	Missing or invalid script arguments, which can include an invalid number of arguments or argument format.
	Logon fails.
	Preparation of SQL query fails.

User monitor type	Probe failure reasons
	Execution of SQL query fails.
SNMP	Monitor fails to establish a connection to the database.
	Missing or invalid script arguments, which can include an invalid number of arguments or argument format.
	Logon fails.
	Monitor fails to create the SNMP session.
	Monitor fails to find the object identifier.
	The monitor threshold value setting is greater than or equal to the actual threshold of the monitor.
RDP (Windows Terminal Server)	Missing or invalid script arguments, which can include an invalid number of arguments or argument format.
	Monitor fails to create a socket.
	Mismatch in versions.
	Monitor fails to confirm connection.

You can view the log file from the NetScaler command line by using the following commands, which open a BSD shell, display the log file on the screen, and then close the BSD shell and return you to the NetScaler command prompt:

```
> shell
root@ns# cat /var/nslog/nsumond.log
root@ns# exit
>
```

User monitors also have a time-out value and a retry count for probe failures. You can use user monitors with non-user monitors. During high CPU utilization, a non-user monitor enables faster detection of a server failure.

If the user monitor probe times out during high CPU usage, the state of the service remains unchanged.

> **Note**
>
> For scriptable monitors, the response timeout must be configured to a value equal to expected timeout + 1 second.
>
> For example, if you expect the timeout to be 4 seconds, configure the response timeout as 5 seconds.

Example command:

add lb monitor <name> USER –scriptname <script-name> -resptimeout 5 seconds

How to Use a User Monitor to Check Web Sites

Feb 13, 2017

You can configure a user monitor to check for specific Web site problems that are reported by HTTP servers using specific HTTP codes. The following table lists the HTTP response codes that this user monitor expects.

HTTP response code	Meaning
200 - success	Probe success.
503 - service unavailable	Probe failure.
404 - not found	Script not found or cannot execute.
500 - Internal server error	Internal error/resource constraints in dispatcher (out of memory, too many connections, unexpected system error, or too many processes). The service is not marked DOWN.
400 - bad request	Error parsing HTTP request.
502 - bad gateway	Error decoding script's response.

You configure the user monitor for HTTP by using the following parameters.

Parameter	Specifies
scriptName	The path and name of the script to execute.
scriptArgs	The strings that are added in the POST data. They are copied to the request verbatim.
dispatcherIP	The IP address of the dispatcher to which the probe is sent.
dispatcherPort	The port of the dispatcher to which the probe is sent.
localfileName	The name of a monitor script file on the local system.

Parameter	Specifies
destPath	A particular location on the NetScaler appliance where the uploaded local file is stored.

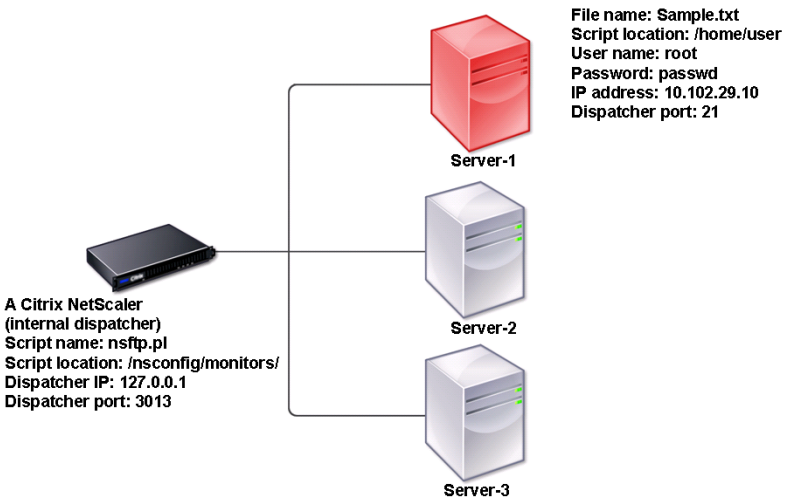
To create a user monitor to monitor HTTP, see Configuring Monitors in a Load Balancing Setup.

Understanding the Internal Dispatcher

Mar 19, 2012

You can use a custom user monitor with the internal dispatcher. Consider a case where you need to track the health of a server based on the presence of a file on the server. The following diagram illustrates this scenario.

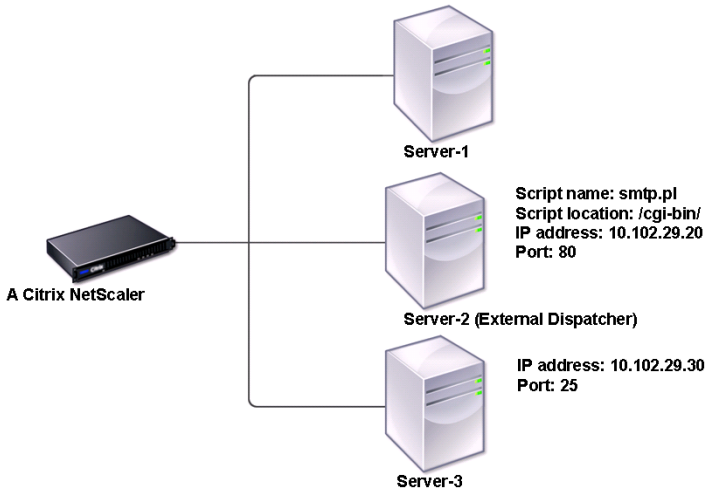
Figure 1. Using a User Monitor with the Internal Dispatcher



A possible solution is to use a Perl script that initiates an FTP session with the server and checks for the presence of the file. You can then create a user monitor that uses the Perl script. The NetScaler includes such a Perl script (nsftp.pl), in the /nsconfig/monitors/ directory.

You can use a user monitor with an external dispatcher. Consider a case where you must track the health of a server based on the state of an SMTP service on another server. This scenario is illustrated in the following diagram.

Figure 2. Using a User Monitor with an External Dispatcher



A possible solution would be to create a Perl script that checks the state of the SMTP service on the server. You can then create a user monitor that uses the Perl script.

Configuring a Custom User Monitor

Dec 22, 2016

To configure a custom user monitor, you must first write the script that performs the action that the monitor will use to check the service that is bound to it, and upload the script to the /nsconfig/monitors directory on the NetScaler appliance. Then you create the monitor on the appliance, as described below.

Note: Monitor probes originate from the NetScaler IP (NSIP) address.

To configure a user monitor by using the command line interface

At the command prompt, type:

add lb monitor <monitorName> USER -scriptname <NameOfScript> -scriptargs <Arguments>

Example

add monitor Monitor-User-1 USER -scriptname nsftp.pl -scriptargs "file=/home/user/sample.txt;user=root;password=passwd"

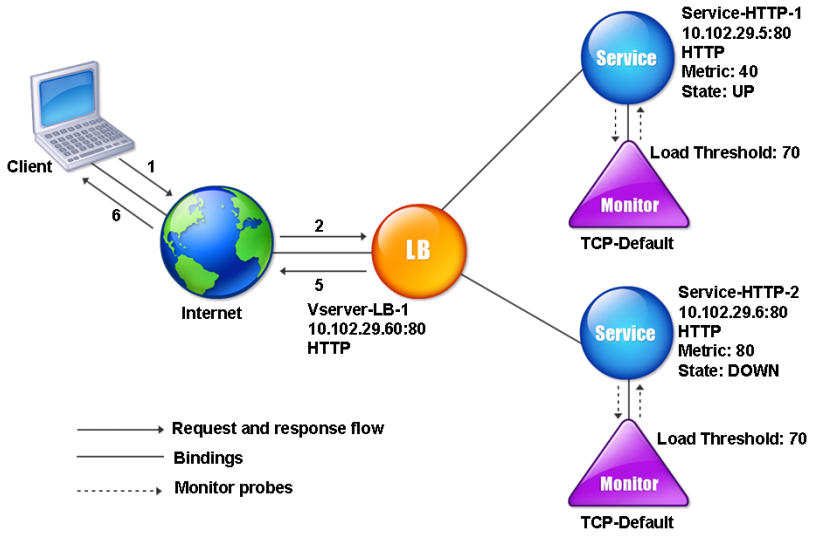
Understanding Load Monitors

Feb 13, 2017

Load monitors use SNMP polled OIDs to calculate load. The load monitor uses the IP address of the service to which it is bound (the destination IP address) for polling. It sends an SNMP query to the service, specifying the OID for a metric. The metrics can be CPU, memory, or number of server connections. The server responds to the query with a metric value. The metric value in the response is compared with the threshold value. The NetScaler appliance considers the service for load balancing only if the metric is less than the threshold value. The service with the lowest load value is considered first.

The following diagram illustrates a load monitor configured for the services described in the basic load balancing setup discussed in Setting Up Basic Load Balancing.

Figure 1. Operation of Load Monitors



Note: The load monitor does not determine the state of the service. It only enables the appliance to consider the service for load balancing.

After you configure the load monitor, you must then configure the metrics that the monitor will use. For load assessment, the load monitor considers server parameters known as metrics, which are defined within the metric tables in the appliance configuration. Metric tables can be of two types:

- **Local.** By default, this table exists in the appliance. It consists of four metrics: connections, packets, response time, and bandwidth. The appliance specifies these metrics for a service, and SNMP queries are not originated for these services. These metrics cannot be changed.
- **Custom.** A user-defined table. Each metric is associated with an OID.

By default, the appliance generates the following tables:

- NetScaler
- RADWARE
- CISCO-CSS
- LOCAL

- FOUNDRY
- ALTEON

You can either add the appliance-generated metric tables, or you can add tables of your own choosing, as shown in the following table. The values in the metric table are provided only as examples. In an actual scenario, consider the real values for the metrics.

Metric name	OIDs	Weight	Threshold
CPU	1.2.3.4	2	70
Memory	4.5.6.7	3	80
Connections	5.6.7.8	4	90

To calculate the load for one or more metrics, you assign a weight to each metric. The default weight is 1. The weight represents the priority given to each metric. If the weight is high, the priority is high. The appliance chooses a service based on the SOURCEIPDESTIP hash algorithm.

You can also set the threshold value for each metric. The threshold value enables the appliance to select a service for load balancing if the metric value for the service is less than the threshold value. The threshold value also determines the load on each service.

Configuring Load Monitors

Feb 13, 2017

To configure a load monitor, first create the load monitor. For instructions on creating a monitor, see Creating Monitors. Next, select or create the metric table to define a set of metrics that determine the state of the server, and (if you create a metric table) bind each metric to the metric table.

To create a metric table by using the command line interface

At the command prompt, type the following commands:

- add lb metricTable <metricTableName>
- bind lb metricTable <metricTableName> <metric> <SNMPOID>

Example

```
add metricTable Table-Custom-1

bind metricTable Table-Custom-1 1.3.6.1.4.1.5951.4.1.1.41.1.5 11
```

To create a metric table and bind metrics to it by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Metric Tables and create a metric table.
2. To bind metrics, click Bind and specify a metric and an SNMP OID.

Unbinding Metrics from a Metrics Table

Nov 12, 2013

You can unbind metrics from a metrics table if the metrics need to be changed, or if you want to remove the metrics table entirely.

To unbind metrics from a metric table by using the command line interface

At the command prompt, type:

unbind lb metricTable <metricTable> <metric>

Example

unbind metricTable Table-Custom-1 1.3.6.1.4.1.5951.4.1.1.41.1.5

To unbind metrics from a metric table by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Metric Tables.
2. Open a metric table, select a metric, and click Delete.

You can view the detail of all configured metric tables, such as name and type, to determine whether the metric table is internal or created and configured.

Configuring Reverse Monitoring for a Service

Dec 22, 2016

A reverse monitor marks a service as DOWN if the probe criteria are satisfied and UP if they are not satisfied. For example, if you want a backup service to receive traffic only when the primary service is DOWN, you can bind a reverse monitor to the secondary service but configure it to probe the primary service.

The NetScaler appliance supports the following reverse monitors:

- HTTP
- ICMP
- TCP (from release 11.1 build 49.x)

Configuring HTTP Reverse Monitoring for a Service

The following table describes the conditions of HTTP direct and reverse monitoring for a service:

Condition	Direct	Reverse
Connection not established.	Fail	Fail
HTTP response code matches the probe's specifications.	Success	Fail
HTTP response code does not match the probe's specifications.	Fail	Success
Probe timed out.	Fail	Fail

To configure HTTP reverse monitoring for a service by using the NetScaler command line

At the command prompt, type:

>add lb monitor <Monitor_Name> HTTP -respCode 200 -httpRequest "HEAD /" -destIP <Primary_Service_IP_Address> -destPort 80 -reverse YES

>bind service <Secondary_Service_Name> -monitorname <Monitor_Name>

Configuring ICMP Reverse Monitoring for a Service

The following table describes the conditions of ICMP direct and reverse monitoring for a service:

Condition	Direct	Reverse
ICMP echo reply is received.	Success	Fail
Probe timed out.	Fail	Success

To configure ICMP reverse monitoring for a service by using the NetScaler command line

At the command prompt, type:

>add lb monitor <Monitor_Name> PING -destIP <Primary_Service_IP_Address> -reverse YES

>bind service <Secondary_Service_Name> -monitorname <Monitor_Name>

Configuring TCP Reverse Monitoring for a Service

If a direct TCP monitor receives a RESET in response to a monitor probe, the service is marked DOWN. However, if a reverse TCP monitor receives a RESET response, the probe is considered successful, and the service is marked UP.

The following table describes the conditions of TCP reverse monitoring for a service:

Condition	Direct	Reverse
TCP connection is established.	Success	Fail
Probe timed out.	Fail	Fail
Response to probe is RESET.	Fail	Success

To configure TCP reverse monitoring for a service by using the NetScaler command line

At the command prompt, type:

add lb monitor <Monitor_Name> TCP –destip <Primary_Service_IP_Address> -destport <primary_service_port> –reverse YES

>bind service <Secondary_Service_Name> -monitorname <Monitor_Name>

To configure reverse monitoring by using the NetScaler GUI

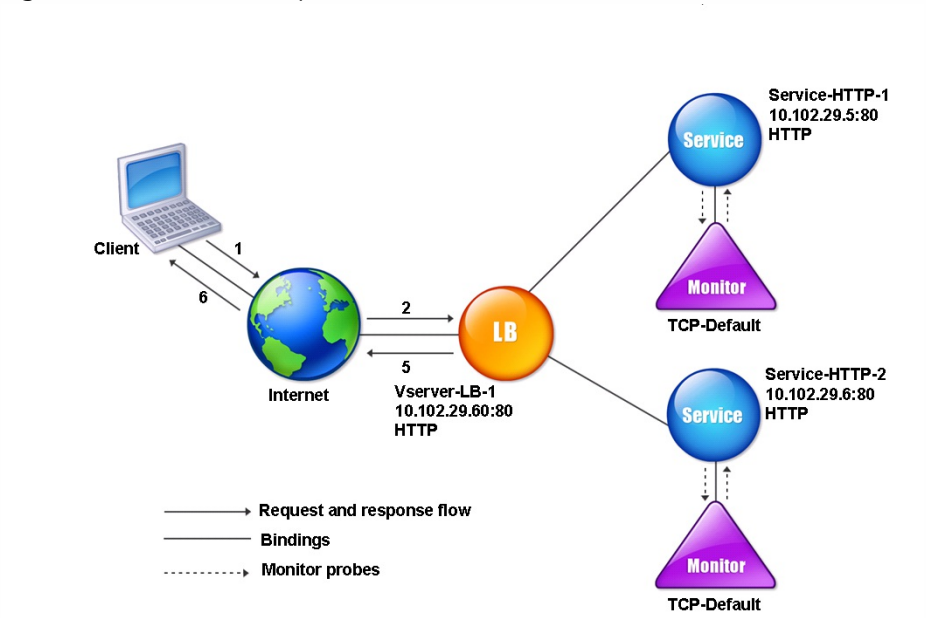
1. Navigate to **Traffic Management** > **Load Balancing** > **Monitors**.
2. Create an HTTP, ICMP, or TCP monitor and select **Reverse**.

Configuring Monitors in a Load Balancing Setup

Jul 05, 2017

To configure monitors on a Web site, you first decide whether to use a built-in monitor or create your own monitor. If you create a monitor, you can choose between creating a monitor based on a built-in monitor, or creating a custom monitor that uses a script that you write to monitor the service. For more information about creating custom monitors, see Custom Monitors. Once you have chosen or created a monitor, you then bind it to the appropriate service. The following conceptual diagram illustrates a basic load balancing setup with monitors.

Figure 1. How Monitors Operate



As shown above, each service has a monitor bound to it. The monitor probes the load balanced server via its service. As long as the load balanced server responds to the probes, the monitor marks it UP. If the load balanced server should fail to respond to the designated number of probes within the designated time period, the monitor marks it DOWN.

This section includes the following details:

- Creating Monitors
- Binding Monitors to Services
- Modifying Monitors
- Enabling and Disabling Monitors
- Unbinding Monitors
- Removing Monitors
- Viewing Monitors
- Closing Monitor Connections
- Ignoring the Upper Limit on Client Connections for Monitor Probes

Creating Monitors

Nov 12, 2013

The NetScaler appliance provides a set of built-in monitors. It also allows you to create custom monitors, either based on the built-in monitors or from scratch.

To create a monitor by using the command line interface

At the command prompt, type:

add lb monitor <monitorName> <monitorType> [<interval>]

Example

add lb mon monitor-HTTP-1 HTTP

add lb mon monitor-HTTP-2 TCP 2

To create a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors, and create a monitor.

Binding Monitors to Services

Nov 12, 2013

After creating a monitor, you bind it to a service. You can bind one or multiple monitors to a service. If you bind one monitor to a service, that monitor determines whether the service is marked UP or DOWN. If you bind multiple monitors to a service, the NetScaler appliance checks all monitors bound to that service using a calculation that you control, and marks the service UP or DOWN depending on the results.

Note: The destination IP address of a monitor probe can be different than the server IP address and port.

To bind a monitor to a service by using the command line interface

At the command prompt, type:

bind lb monitor <monitorName> <ServiceName>

Example

bind mon monitor-HTTP-1 Service-HTTP-1

To bind a monitor to a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open the service, and add a monitor.

Modifying Monitors

Nov 12, 2013

You can modify the settings for any monitor that you created.

Note: Two sets of parameters apply to monitors: those that apply to all monitors, regardless of type, and those that are specific to a monitor type. For information on parameters for a specific monitor type, see the description for that type of monitor.

To modify an existing monitor by using the command line interface

At the command prompt, type:

set lb monitor <monitorName> <type> -interval <interval> -resptimeout <resptimeout>

Example

set mon monitor-HTTP-1 HTTP -interval 50 milli
-resptimeout 20 milli

To modify an existing monitor by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors, and open a monitor to modify.

Enabling and Disabling Monitors

Nov 12, 2013

By default, monitors bound to services and service groups are enabled. When you enable a monitor, the monitor begins probing the services to which it is bound. If you disable a monitor bound to a service, the state the service is determined using the other monitors bound to the service. If the service is bound to only one monitor, and if you disable the monitor, the state of the service is determined using the default monitor.

To enable a monitor by using the command line interface

At the command prompt, type:

enable lb monitor <monitorName>

Example

enable lb mon monitor-HTTP-1

To enable a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Select a monitor, and from the Action list, select Enable or Disable.

To disable a monitor by using the command line interface

At the command prompt, type:

disable lb monitor <monitorName>

Example

disable lb mon monitor-HTTP-1

Unbinding Monitors

Nov 12, 2013

You can unbind monitors from a service and service group. When you unbind a monitor from the service group, the monitors are unbound from the individual services that constitute the service group. When you unbind a monitor from a service or a service group, the monitor does not probe the service or the service group.

Note: When you unbind all user-configured monitors from a service or a service group, the default monitor is bound to the service and the service group. The default monitors then probes the service or the service groups.

To unbind a monitor from a service by using the command line interface

At the command prompt, type:

unbind lb monitor <monitorName>

Example

unbind mon monitor-HTTP-1 Service-HTTP-1

To unbind a monitor from a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service to modify.
2. Click in the Monitors section, select a monitor, and click Unbind.

Removing Monitors

Nov 12, 2013

After you unbind a monitor that you created from its service, you can remove that monitor from the NetScaler configuration. (If a monitor is bound to a service, it cannot be removed.)

Note: When you remove monitors bound to a service, the default monitor is bound to the service. You cannot remove default monitors.

To remove a monitor by using the command line interface

At the command prompt, type:

rm lb monitor <monitorName> <type>

Example

rm lb monitor monitor-HTTP-1 HTTP

To remove a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Select a monitor, and click Delete.

Viewing Monitors

Nov 12, 2013

You can view the services and service groups that are bound to a monitor. You can verify the settings of a monitor to troubleshoot your NetScaler configuration. The following procedure describes the steps to view the bindings of a monitor to the services and service groups.

To view monitor bindings by using the command line interface

At the command prompt, type:

show lb monbindings <MonitorName>

Example

show lb monbindings monitor-HTTP-1

To view monitor bindings by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Select a monitor, and in the Action list, click Show Bindings.

To view monitors by using the command line interface

At the command prompt, type:

show lb monitor <monitorName>

Example

show lb mon monitor-HTTP-1

To view monitors by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors. The details of the available monitors appear in the Monitors pane.

Closing Monitor Connections

Jul 01, 2016

The NetScaler appliance sends probes to the services through the monitors bound to the services. By default, the monitor on the NetScaler and the physical server follow the complete handshake procedure even for monitor probes. However, this procedure adds overhead to the monitoring process and may not be always necessary.

For the TCP monitors, you can configure the NetScaler to close a monitor-probe connection after receiving SYN-ACK from the service. To do so, set the value of the monitorConnectionClose parameter to RESET. If you want the monitor-probe connection to go through the complete procedure, set the value to FIN.

Note: The monitorConnectionClose setting is applicable to all the monitors bound to all the services configured on the NetScaler appliance.

To configure monitor-connection closure by using the command line interface

At the command prompt, type:

set lb parameter -monitorConnectionClose <monitor_conn_close_option>

Example

set lb parameter -monitorConnectionClose RESET

To configure monitor-connection closure by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Configure Load Balancing Parameters.
2. Select FIN or Reset.

Closing Monitor Connections at the Service or Service Group Level

You can also configure the appliance to close a monitor-probe connection at the service and service group level by setting the monConnectionClose parameter. If this parameter is not set, the monitor connection is closed by using the value set in the global load balancing parameters. If this parameter is set at the service or service group level, the monitor connection is closed by sending a connection termination message, with the FIN or RESET bit set, to the service or service group.

To configure monitor-connection closure at the service level by using the NetScaler command line

At the command prompt, type:

> **set service** <service_name> -**monConnectionClose** (**RESET** | **FIN**)

To configure monitor-connection closure at the service group level by using the NetScaler command line

At the command prompt, type:

> **set serviceGroup** <service_name> -**monConnectionClose** (**RESET** | **FIN**)

To configure monitor-connection closure at the service level by using the NetScaler GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**.
2. Add or edit a service, and in **Basic Settings**, set the **Monitoring Connection Close Bit**.

To configure monitor-connection closure at the service group level by using the NetScaler GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Add or edit a service group, and in **Basic Settings**, set the **Monitoring Connection Close Bit**.

Ignoring the Upper Limit on Client Connections for Monitor Probes

Aug 29, 2013

Depending on considerations such as the capacity of a physical server, you can specify a limit on the maximum number of client connections made to any service. If you have set such a limit on a service, the NetScaler appliance stops sending requests to the service when the threshold is reached and resumes sending connections to the service after the number of existing connections falls to within the limits. You can configure the NetScaler to skip this check when it sends monitor-probe connections to a service.

Note: You cannot skip the maximum-client-connections check for an individual service. If you specify this option, it applies to all the monitors bound to all the services configured on the NetScaler appliance.

To set the Skip MaxClients for Monitor Connections option by using the command line interface

At the command prompt, type:

set lb parameter -monitorSkipMaxClient (ENABLED | DISABLED)

Example

set lb parameter -monitorSkipMaxClient enabled

To set the Skip MaxClients for Monitor Connections option by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Configure Load Balancing Parameters.
2. Select Skip MaxClients for Monitoring Connections.

Managing a Large Scale Deployment

Mar 19, 2012

The NetScaler appliance contains several features that are helpful when you are configuring a large load balancing deployment. Instead of configuring virtual servers and services individually, you can create groups of virtual servers and services. You can also create a range of virtual servers and services, and you can translate or mask virtual server and service IP addresses.

You can set persistence for a group of virtual servers. You can bind monitors to a group of services. Creating a range of virtual servers and services of identical type allows you to set up and configure those servers in a single procedure, which significantly shortens the time required to configure those virtual servers and services.

By translating or masking IP addresses, you can take down virtual servers and services, and make changes to your infrastructure, without extensive reconfiguration of your service and virtual server definitions.

Ranges of Virtual Servers and Services

Mar 19, 2012

When you configure load balancing, you can create ranges of virtual servers and services, eliminating the need to configure virtual servers and services individually. For example, you can use a single procedure to create three virtual servers with three corresponding IP addresses. When more than one argument uses a range, all of the ranges must be of the same size.

The following are the types of ranges you can specify when adding services and virtual servers to your configuration:

- **Numeric ranges.** Instead of typing a single number, you can specify a range of consecutive numbers.

  For example, you can create a range of virtual servers by specifying a starting IP address, such as 10.102.29.30, and then typing a value for the last byte that indicates the range, such as 34. In this example, five virtual servers will be created with IP addresses that range between 10.102.29.30 and 10.102.29.34.

  Note: The IP addresses of the virtual servers and services must be consecutive.
- **Alphabetic ranges.** Instead of typing a literal letter, you can substitute a range for any single letter, for example, [C-G]. This results in all letters in the range being included, in this case C, D, E, F, and G.

  For example, if you have three virtual servers named Vserver-x, Vserver-y, and Vserver-z, instead of configuring them separately, you can type vserver [x-z] to configure them all.

Creating a Range of Virtual Servers

Updated: 2013-11-12

You create a range of virtual servers as described below.

To create range of virtual servers by using the command line interface

At the command prompt, type one of the following commands:

- add lb vserver <name>@ <protocol> -range <rangeValue> <IPAddress> [<port>]
- add lb vserver <name>@**[**<rangeValue>**]**> <protocol> <IPAddress[<rangeValue>]> [<port>]

Example

add lb vserver Vserver-LB-2 http -range 6 10.102.29.30 80

OR

> add lb vserver vserver[P-R] http 10.102.29.[26-28] 80
vserver "vserverP" added
vserver "vserverQ" added
vserver "vserverR" added
Done

To create range of virtual servers by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Add a virtual server, and specify a range.

Creating a Range of Services

Updated: 2013-11-12

You create a range of services as described below. If you specify a range for the service name, specify a range for the IP address too.

To create range of services by using the command line interface

At the command prompt, type the command:

add service <name>@ <IP>@ <protocol> <port>

Example

```
> add service serv[1-3] 10.102.29.[102-104] http 80
service "serv1" added
service "serv2" added
service "serv3" added
 Done
```

Configuring Service Groups

Jan 04, 2016

Configuring a service group enables you to manage a group of services as easily as a single service. For example, if you enable or disable any option, such as compression, health monitoring or graceful shutdown, for a service group, the option gets enabled for all the members of the service group.

After creating a service group, you can bind it to a virtual server, and you can add services to the group. You can also bind monitors to service groups.

The members of a service group can be identified by IP address or server name.

Using domain-name based service (DBS) group members is advantageous because you need not reconfigure the member on the NetScaler appliance if the IP address of the member changes. The appliance automatically senses such changes through the configured name server. This feature is particularly useful in cloud scenarios, where the service provider can change a physical server or change the IP address for a service. If you specify a DBS group member, the NetScaler learns the IP address dynamically.

You can bind both IP-based and DBS members to the same service group.

Note: If you use DBS service group members, make sure that either a name server is specified or a DNS server is configured on the NetScaler. A domain name will be resolved into an IP address only if the corresponding address record is present on the NetScaler or the name server.

Creating Service Groups

You can configure up to 8192 service groups on the NetScaler appliance.

To create a service group by using the command line

At the command prompt, type:

add servicegroup <ServiceGroupName> <Protocol>

Example

```
add servicegroup Service-Group-1 HTTP
```

To create a service group by using the configuration utility

Navigate to Traffic Management > Load Balancing > Service Groups, and add a service group.

Binding a Service Group to a Virtual Server

When you bind a service group to a virtual server, the member services are bound to the virtual server.

To bind a service group to a virtual server by using the command line interface

At the command prompt, type:

bind lb vserver <name>@ <serviceGroupName>

Example

```
bind lb vserver Vserver-LB-1 Service-Group-1
```

To bind a service group to a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In Advanced Settings, select Service Groups.

Binding a Member to a Service Group

Adding services to a service group enables the service group to manage the servers. You can add the servers to a service group by specifying the IP addresses or the names of the servers.

In the configuration utility, if you want to add a domain-name based service group member, select Server Based.

With this option, you can add any server that has been assigned a name, regardless of whether the name is an IP address or a user-assigned name.

To add members to a service group by using the command line interface

To configure a service group, at the command prompt, type:

bind servicegroup <serviceGroupName> (<IP>@ | <serverName>) <port>
Examples

bind servicegroup Service-Group-1 10.102.29.30 80

bind servicegroup Service-Group-2 1000:0000:0000:0000:0005:0600:700a:888b 80

bind servicegroup CitrixEdu s1.citrite.net

To add members to a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groupsand open a service group.
2. Click in the Service Group section, and do one of the following:
   - To add a new IP based service group member, select IP Based.
   - To add a server-name based service group member, select Server Based.

   If you want to add a domain-name based service group member, select **Server Based**. With this option, you can add any server that has been assigned a name, regardless of whether the name is an IP address or a user-assigned name.
3. If adding a new IP based member, in the IP Address text box, type the IP address. If the IP address uses IPv6 format, select the IPv6 check box and then enter the address in the IP Address text box.

   Note: You can add a range of IP addresses. The IP addresses in the range must be consecutive. Specify the range by entering the starting IP address in the IP Address text box (for example, 10.102.29.30). Specify the end byte of the IP address range in the text box under Range (for example, 35). In the Port text box type the port (for example, 80), and then click Add.
4. Click Create.

Binding a Monitor to a Service Group

When you create a service group, the default monitor of the type appropriate for the group is automatically bound to it. Monitors periodically probe the servers in the service group to which they are bound and update the state of the service groups.

You can bind a different monitor of your own choice to the service group.

To bind a monitor to a service group by using the command line interface

At the command prompt, type:

bind serviceGroup <serviceGroupName> -monitorName <string> -monState (ENABLED | DISABLED)
Example

bind serviceGroup Service-Group-1 -monitorName monitor-HTTP-1

To a bind monitor to a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Open a service group and, in Advanced Settings, click Monitors.

Retaining the Original State of a Service Group Member after Disabling and Enabling a Virtual Server

From build 64.x, a new global option, –retainDisableServer, enables you to retain a service-group member's state when a server is disabled and reenabled.

Previously, a member's state would change from DISABLED to ENABLED under the following set of conditions:

- Two applications are deployed on the same port on a virtual server.
- Two service groups with a common member are bound to this virtual server, and the common member is enabled in one group and disabled in the other.
- The server is disabled and then reenabled.

Under these conditions, disabling the server disables all the service group members, and reenabling the server enables all the members, by default, regardless of their earlier states. To bring the members back to the original states, you must manually disable those member(s) in the service group. This is a cumbersome task and prone to errors.

Managing Service Groups

Feb 13, 2017

You can change the settings of the services in a service group, and you can perform tasks such as enabling, disabling, and removing service groups. You can also unbind members from a service group.

To manage service groups, see the following sections:

- Modifying a Service Group
- Removing a Service Group
- Unbinding a Member from a Service Group
- Unbinding a Service Group from a Virtual Server
- Unbinding Monitors from Service Groups
- Enabling or Disabling a Service Group
- Viewing the Properties of a Service Group
- Viewing Service Group Statistics
- Load Balancing Virtual Servers Bound to a Service Group

Modifying a Service Group

Updated: 2013-11-12

You can modify attributes of service group members. You can set several attributes of the service group, such as maximum client, SureConnect, and compression. The attributes are set on the individual servers in the service group. You cannot set parameters on the service group such as transport information (IP address and port), weight, and server ID.

Note: A parameter you set for a service group is applied to the member servers in the group, not to individual services.

To modify a service group by using the command line interface

At the command prompt, type the following command with one or more of the optional parameters:

set servicegroup <serviceGroupName> [-type <type>] [-maxClient <maxClient>] [-maxReq <maxReq>] [-cacheable (YES | NO)] [-cip (ENABLED | DISABLED)] [-cipHeader <cipHeader>] [-usip (YES | NO)] [-sc (ON | OFF)] [-sp (ON | OFF)] [-cltTimeout <cltTimeout>] [-svrTimeout <svrTimeout>] [-cka (YES | NO)] [-TCPB (YES | NO)] [-CMP (**YES** | **NO**)] [-maxBandwidth <maxBandwidth>] [-maxThreshold <maxThreshold>] [-state (ENABLED | DISABLED)] [-downStateFlush (ENABLED | DISABLED)

Example

```
set servicegroup Service-Group-1 -type TRANSPARENT

set servicegroup Service-Group-1 -maxClient 4096

set servicegroup Service-Group-1 -maxReq 16384

set servicegroup Service-Group-1 -cacheable YES
```

To modify a service group by using the configuration utility

Navigate to Traffic Management > Load Balancing > Service Groups, and open the service group to modify.

Removing a Service Group

Updated: 2013-09-04

When you remove a service group, the servers bound to the group retain their individual settings and continue to exist on the NetScaler.

To remove a service group by using the command line interface

At the command prompt, type:

rm servicegroup <ServiceGroupName>
Example

rm servicegroup Service-Group-1

To remove a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Select a service group, and click Delete.

Unbinding a Member from a Service Group

Updated: 2013-11-12

When you unbind a member from the service group, the attributes set on the service group will no longer apply to the member that you unbound. The member services retains its individual settings, however, and continues to exist on the NetScaler.

To unbind members from a service group by using the command line interface

At the command prompt, type:

unbind servicegroup <serviceGroupName> <IP>@ [<port>]
Example

unbind servicegroup Service-Group-1 10.102.29.30 80

To unbind members from a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Open a service group, and click in the Service Group Members section.
3. Select a service group member, and click Unbind.

Unbinding a Service Group from a Virtual Server

Updated: 2013-11-12

When you unbind a service group from a virtual server, the member services are unbound from the virtual server and continue to exist on the NetScaler appliance.

To unbind a service group from a virtual server by using the command line interface

At the command prompt, type:

unbind lb vserver <name>@ <ServiceGroupName>

Example

unbind lb vserver Vserver-LB-1 Service-Group-1

To unbind a service group from a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open the virtual server, and click in the Service Group section.
3. Select the service group, and click Unbind.

Unbinding Monitors from Service Groups

Updated: 2013-12-10

When you unbind a monitor from a service group, the monitor that you unbound no longer monitors the individual services that constitute the group.

To unbind a monitor from a service group using the command line interface

At the command prompt, type:

unbind serviceGroup <serviceGroupName> -monitorName <string>

Example

unbind serviceGroup Service-Group-1 -monitorName monitor-HTTP-1

To unbind a monitor from a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Open a service group, and click in the Monitors section.
3. Select a monitor, and click Unbind.

Enabling or Disabling a Service Group

Updated: 2013-09-04

When you enable a service group and the servers, the services belonging to the service group are enabled. Similarly, when a service belonging to a service group is enabled, the service group and the service are enabled. By default, service groups are enabled.

After disabling an enabled service, you can view the service using the configuration utility or the command line to see the amount of time that remains before the service goes DOWN.

To disable a service group by using the command line interface

At the command prompt, type:

disable servicegroup <ServiceGroupName>

Example

disable servicegroup Service-Group-1

To disable a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Select a service group, and in the Action list, click Disable.

To enable a service group by using the command line interface

At the command prompt, type:

enable servicegroup <ServiceGroupName>

Example

```
enable servicegroup Service-Group-1
```

To enable a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Select a service group, and in the Action list, click Enable.

Viewing the Properties of a Service Group

Updated: 2013-09-04

You can view the following settings of the configured service groups: name, IP address, state, protocol, maximum client connections, maximum requests per connection, maximum bandwidth, and monitor threshold. Viewing the details of the configuration can be helpful for troubleshooting your configuration.

To view the properties of a service group by using the command line interface

At the command prompt, type one of the following commands to display the group properties or the properties and the group members:

- show servicegroup <ServiceGroupName>
- show servicegroup <ServiceGroupName> -includemembers

Example

```
show servicegroup Service-Group-1
```

To view the properties of a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Click the arrow next to the service group.

Viewing Service Group Statistics

Updated: 2013-09-04

You can view service-group statistical data, such as rate of requests, responses, request bytes, and response bytes. The NetScaler appliance uses the statistics of a service group, such as these, to balance the load on the services.

To view the statistics of a service group by using the command line interface

At the command prompt, type:

stat servicegroup <ServiceGroupName>

Example

stat servicegroup Service-Group-1

To view the statistics of a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Select a service group, and click Statistics.

Load Balancing Virtual Servers Bound to a Service Group

Updated: 2013-09-04

In large-scale deployments, the same service group can be bound to multiple load balancing virtual servers. In such a case, instead of viewing each virtual server to see the service group it is bound to, you can view a list of all the load balancing virtual servers bound to a service group. You can view the following details of each virtual server:

- Name
- State
- IP address
- Port

To display the virtual servers bound to a service group by using the command line interface

At the command prompt, type the following command to display the virtual servers bound to a service group:

show servicegroupbindings <serviceGroupName>
Example

> show servicegroupbindings SVCGRPDTLS
SVCGRPDTLS - State :ENABLED
1) Test-pers (10.10.10.3:80) - State : DOWN
2) BRVSERV (10.10.1.1:80) - State : DOWN
3) OneMore (10.102.29.136:80) - State : DOWN
4) LBVIP1 (10.102.29.66:80) - State : UP
Done
>

To display the virtual servers bound to a service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Service Groups.
2. Select a service group, and in the Action list, click Show Bindings.

Configuring Automatic Domain Based Service Group Scaling

Aug 06, 2017

A domain based service group consists of members whose IP addresses are obtained by resolving the domain names of servers that are bound to the service group. The domain names are resolved by a name server whose details you configure on the appliance. A domain based service group can also include IP-address based members.

The process of name resolution for a domain based server might return more than one IP address. The number of IP addresses in the DNS response is determined by the number of address (A) records configured for the domain name, on the name server. Even if the name resolution process returns multiple IP addresses, only one IP address is bound to the service group. To scale up or scale down a service group, you need to manually bind and unbind additional domain based servers to and from the service group, respectively.

However, you can configure a domain based service group to scale automatically on the basis of the complete set of IP addresses returned by a DNS name server for a domain based server. To configure automatic scaling, when binding a domain based server to a service group, enable the automatic scaling option. Following are the steps for configuring a domain based service group that scales automatically:

- Add a name server for resolving domain names. For more information about configuring a name server on the appliance, see Adding a Name Server.
- Add a domain based server. For information about adding a domain based server, see Adding a Server.
- Add a service group and associate the domain based server to the service group, with the autoscale option set to DNS. For information about adding a service group, see Configuring Service Groups.

When a domain based server is bound to a service group and the automatic scaling option is set on the binding, a UDP monitor and a TCP monitor are automatically created and bound to the domain based server. The two monitors function as resolvers. The TCP monitor is disabled by default, and the appliance uses the UDP monitor to send DNS queries to the name server to resolve the domain name. If the DNS response is truncated (has the TC flag set to 1), the appliance falls back to TCP and uses the TCP monitor to send the DNS queries over TCP. Thereafter, the appliance continues to use only the TCP monitor.

The DNS response from the name server might contain multiple IP addresses for the domain name. With the automatic scaling option set, the appliance polls each of the IP addresses by using the default monitor, and then includes in the service group only those IP addresses that are up and available. After the IP address records expire, as defined by their time-to-live (TTL) values, the UDP monitor (or the TCP monitor, if the appliance has fallen back to using the TCP monitor) queries the name server for domain resolution and includes any new IP addresses in the service group. If an IP address that is part of the service group is not present in the DNS response, the appliance removes that address from the service group after gracefully closing existing connections to the group member, a process during which it does not allow any new connections to be established with the member. If a domain name that resolved successfully in the past results in an NXDOMAIN response, all the service group members associated with that domain are removed.

Static (IP-address based) members and dynamically scaling domain based members can coexist in a service group. You can also bind members with different domain names to a service group with the automatic scaling option set. However, each domain name associated with a service group must be unique within the service group. You must enable the automatic scaling option for each domain based server that you want to use for automatic service group scaling. If an IP address is common to one or more domains, the IP address is added to the service group only once.

To configure a service group to scale automatically by using the command line interface

At the command prompt, type the following commands to configure the service group and verify the configuration:

- add serviceGroup <serviceGroupName> <serverName> <port> -autoScale (**YES** | **NO**)
- show serviceGroup <serviceGroupName>

Example

In the following example, server1 is a domain based server. The DNS response contains multiple IP addresses. Five addresses are available and are added to the service group.

```
> add serviceGroup servGroup server1 80 -autoScale YES
 Done
> sh servicegroup servGroup
      servGroup - HTTP
       State: ENABLED  Monitor Threshold : 0
            . . .
            . . .
      1)   192.0.2.31:80   State: UP      Server Name: server1 (Auto scale)    Server ID: None Weight: 1

            Monitor Name: tcp-default      State: UP
            Probes: 2      Failed [Total: 0 Current: 0]
            Last response: Success - TCP syn+ack received.

      2)   192.0.2.32:80   State: UP      Server Name: server1 (Auto scale)    Server ID: None Weight: 1

            Monitor Name: tcp-default      State: UP
            Probes: 2      Failed [Total: 0 Current: 0]
            Last response: Success - TCP syn+ack received.

      3)   192.0.2.36:80   State: UP      Server Name: server1 (Auto scale)    Server ID: None Weight: 1

            Monitor Name: tcp-default      State: UP
            Probes: 2      Failed [Total: 0 Current: 0]
            Last response: Success - TCP syn+ack received.

      4)   192.0.2.55:80   State: UP      Server Name: server1 (Auto scale)    Server ID: None Weight: 1

            Monitor Name: tcp-default      State: UP
            Probes: 2      Failed [Total: 0 Current: 0]
            Last response: Success - TCP syn+ack received.

      5)   192.0.2.80:80   State: UP      Server Name: server1 (Auto scale)    Server ID: None Weight: 1

            Monitor Name: tcp-default      State: UP
            Probes: 2      Failed [Total: 0 Current: 0]
            Last response: Success - TCP syn+ack received.
 Done
```

To configure a service group to scale automatically by using the configuration utility

1. Navigate to **Traffic Management** > **Load Balancing** > **Service Groups**.
2. Create a service group, and set the autoscale mode to DNS.

Translating the IP Address of a Domain-Based Server

Nov 12, 2013

To simplify maintenance on the NetScaler appliance and on the domain-based servers that are connected to it, you can configure IP address masks and translation IP addresses. These functions work together to parse incoming DNS packets and substitute a new IP address for a DNS-resolved IP address.

When configured for a domain-based server, IP address translation enables the appliance to locate an alternate server IP address in the event that you take the server down for maintenance or if you make any other infrastructure changes that affect the server.

When configuring the mask, you must use standard IP mask values (a power of two, minus one) and zeros, for example, 255.255.0.0. Non-zero values are only permitted in the starting octets.

When you configure a translation IP for a server, you create a 1:1 correspondence between a server IP address and an alternate server that shares leading or trailing octets in its IP address. The mask blocks particular octets in the original server's IP address. The DNS-resolved IP address is transformed to a new IP address by applying the translation IP address and the translation mask.

For example, you can configure a translation IP address of 10.20.0.0 and a translation mask of 255.255.0.0. If a DNS-resolved IP address for a server is 40.50.27.3, this address is transformed to 10.20.27.3. In this case, the translation IP address supplies the first two octets of the new address, and the mask passes through the last two octets from the original IP address. The reference to the original IP address, as resolved by DNS, is lost. Monitors for all services to which the server is bound also report on the transformed IP address.

When configuring a translation IP address for a domain-based server, you specify a mask and an IP address to which the DNS-resolved IP address is to be translated.

Note: Translation of the IP address is only possible for domain-based servers. You cannot use this feature for IP-based servers. The address pattern can be based on IPv4 addresses only.

To configure a translation IP address for a server by using the command line interface

At the command prompt, type:

add server <name>@ <serverDomainName> -translationIp <translationIPAddress> -translationMask <netMask> -state <ENABLED | DISABLED>

Example

```
add server myMaskedServer www.example.com -translationIp 10.10.10.10 -translationMask
255.255.0.0 -state ENABLED
```

To configure a translation IP address for a server by using the configuration utility

Navigate to Traffic Management > Load Balancing > Servers, create a domain-based server, and specify a translation IP address.

Masking a Virtual Server IP Address

Feb 13, 2017

You can configure a mask and a pattern instead of a fixed IP address for a virtual server. This enables traffic that is directed to any of the IP addresses that match the mask and pattern to be rerouted to a particular virtual server. For example, you can configure a mask that allows the first three octets of an IP address to be variable, so that traffic to 111.11.11.198, 22.22.22.198, and 33.33.33.198 is all sent to the same virtual server.

By configuring a mask for a virtual server IP address, you can avoid reconfiguration of your virtual servers due to a change in routing or another infrastructure change. The mask allows the traffic to continue to flow without extensive reconfiguration of your virtual servers.

The mask for a virtual server IP address works somewhat differently from the IP pattern definition for a server described in Translating the IP Address of a Domain-Based Server. For a virtual server IP address mask, a non-zero mask is interpreted as an octet that is considered. For a service, the non-zero value is blocked.

Additionally, for a virtual server IP address mask, either leading or trailing values can be considered. If the virtual server IP address mask considers values from the left of the IP address, this is known as a forward mask. If the mask considers the values to the right side of the address, this is known as a reverse mask.

Note: The NetScaler appliance evaluates all forward mask virtual servers before evaluating reverse mask virtual servers. When masking a virtual server IP address, you also need to create an IP address pattern for matching incoming traffic with the correct virtual server. When the appliance receives an incoming IP packet, it matches the destination IP address in the packet with the bits that are considered in the IP address pattern, and after it finds a match, it applies the IP address mask to construct the final destination IP address.

Consider the following example:

- Destination IP address in the incoming packet: 10.102.27.189
- IP address pattern: 10.102.0.0
- IP mask: 255.255.0.0
- Constructed (final) destination IP address: 10.102.27.189.

In this case, the first 16 bits in the original destination IP address match the IP address pattern for this virtual server, so this incoming packet is routed to this virtual server.

If a destination IP address matches the IP patterns for more than one virtual server, the longest match takes precedence. Consider the following example:

- Virtual Server 1: IP pattern 10.10.0.0, IP mask 255.255.0.0
- Virtual Server 2: IP pattern 10.10.10.0, IP mask 255.255.255.0
- Destination IP address in the packet: 10.10.10.45.
- Selected virtual server: Virtual Server 2.

The pattern associated with Virtual Server 2 matches more bits than that associated with Virtual Server 1, so IPs that match it will be sent to Virtual Server 2.

Note: Ports are also considered if a tie-breaker is required.

To configure a virtual server IP address mask by using the command line interface

At the command prompt, type:

add lb vserver <name>@ http -ipPattern <ipAddressPattern> -ipMask <ipMask> <listenPort>

Example

Pattern matching based on prefix octets:

add lb vserver myLBVserver http -ippattern 10.102.0.0 -ipmask 255.255.0.0 80

Pattern matching based on trailing octets:

add lb vserver myLBVserver1 http -ippattern 0.0.22.74 -ipmask 0.0.255.255 80

Modify a pattern-based virtual server:

set lb vserver myLBVserver1 -ippattern 0.0.22.74 -ipmask 0.0.255.255

To configure a virtual server IP address mask by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the Address Type list, select IP Pattern, and specify an IP pattern and IP mask.

Configuring Load Balancing for Commonly Used Protocols

Jun 28, 2017

In addition to Web sites and Web-based applications, other types of network-deployed applications that use other common protocols often receive large amounts of traffic and therefore benefit from load balancing. Several of these protocols require specific configurations for load balancing to work properly. Among them are FTP, DNS, SIP, and RTSP.

If you configure your NetScaler appliance to use domain names for your servers rather than IPs, you may also need to set up IP translation and masking for those servers.

To configure load balancing for commonly used protocols, see the following sections:

- Load Balancing for a Group of FTP Servers
- Load Balancing DNS Servers
- Load Balancing Domain-Name Based Services
- Load Balancing a Group of SIP Servers
- Load Balancing RTSP Servers
- Load Balancing of Remote Desktop Protocol (RDP) Servers

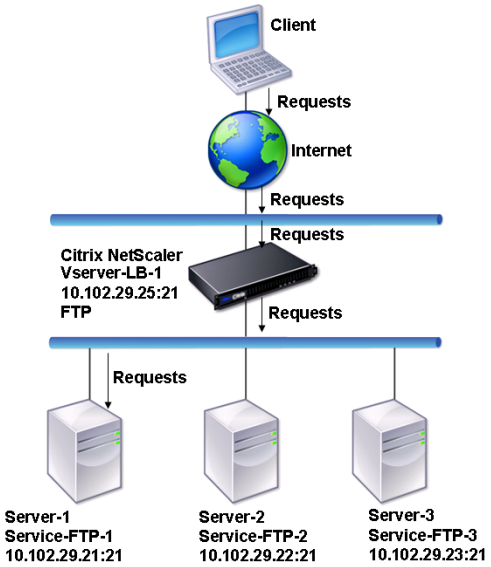
Load Balancing for a Group of FTP Servers

Feb 13, 2017

The NetScaler appliance can be used to load balance FTP servers. FTP requires that the user initiate two connections on two different ports to the same server: the control connection, through which the client sends commands to the server, and the data connection, through which the server sends data to the client. When the client initiates an FTP session by opening a control connection to the FTP server, the appliance uses the configured load balancing method to select an FTP service, and forwards the control connection to it. The load balanced FTP server then opens a data connection to the client for information exchange.

The following diagram describes the topology of a load balancing configuration for a group of FTP servers.

Figure 1. Basic Load Balancing Topology for FTP Servers



In the diagram, the services Service-FTP-1, Service-FTP-2, and Service-FTP-3 are bound to the virtual server Vserver-LB-1. Vserver-LB-1 forwards the client's connection request to one of the services using the least connection load balancing method. Subsequent requests are forwarded to the service that the appliance initially selected for load balancing.

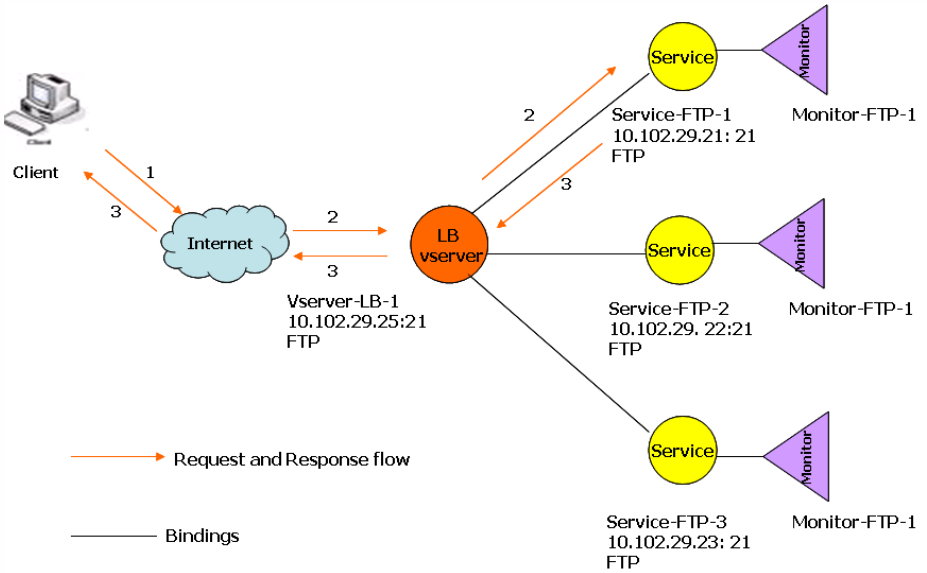
The following table lists the names and values of the basic entities configured on the appliance.

Entity type	Name	IP address	Port	Protocol
Vserver	Vserver-LB-1	10.102.29.25	21	FTP
Services	Service-FTP-1	10.102.29.21	21	FTP
	Service-FTP-2	10.102.29.22	21	FTP
	Service-FTP-3	10.102.29.23	21	FTP

Entity type	Name	IP address	Port	Protocol
Monitors	FTP	None	None	None

The following diagram shows the load balancing entities, and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing FTP Servers Entity Model



The appliance can also provide a passive FTP option to access FTP servers from outside of a firewall. When a client uses the passive FTP option and initiates a control connection to the FTP server, the FTP server also initiates a control connection to the client. It then initiates a data connection to transfer a file through the firewall.

To create services and virtual servers of type FTP, see Setting Up Basic Load Balancing. Name the entities and set the parameters to the values described in the columns of the previous table. When you configure a basic load balancing setup, a default monitor is bound to the services.

Next, bind the FTP monitor to the services by following the procedure described in the section Binding Monitors to Services.

To create FTP monitors by using the command line interface

At the command prompt, type:

add lb monitor <MonitorName> FTP -interval <Interval> -userName <UserName> -password <Password>

Example

add lb monitor monitor-FTP-1 FTP -interval 360 -userName User -password User

To create FTP monitors by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Create a monitor of type FTP, and in Special Parameters, specify a user name and password.

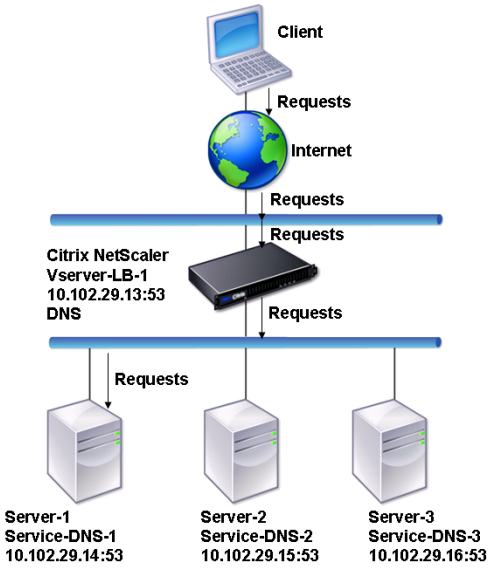
Load Balancing DNS Servers

Feb 13, 2017

When you request DNS resolution of a domain name, the NetScaler appliance uses the configured load balancing method to select a DNS service. The DNS server to which the service is bound then resolves the domain name and returns the IP address as the response. The appliance can also cache DNS responses and use the cached information to respond to future requests for resolution of the same domain name. Load balancing DNS servers improves DNS response times.

The following diagram describes the topology of a load balancing configuration that load balances a group of DNS services.

Figure 1. Basic Load Balancing Topology for DNS Servers

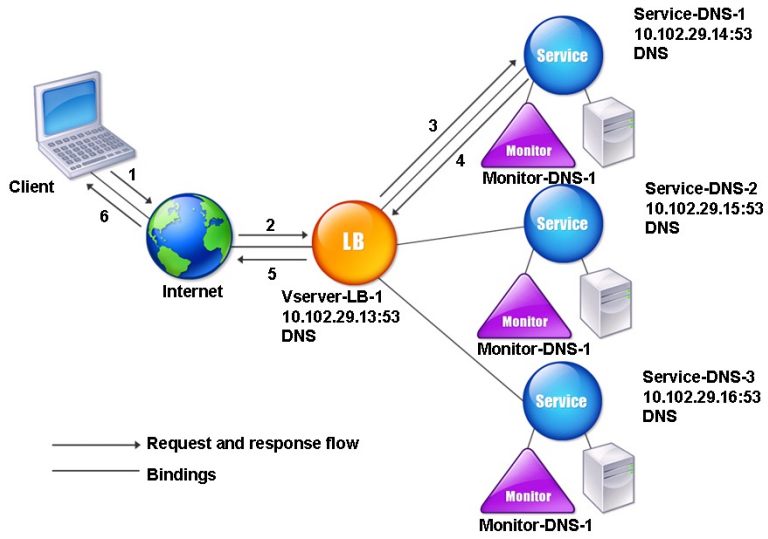


In the diagram, the services Service-DNS-1, Service-DNS-2, and Service-DNS-3 are bound to the virtual server Vserver-LB-1. The virtual server Vserver-LB-1 forwards client requests to a service using the least connection load balancing method. The following table lists the names and values of the basic entities configured on the appliance.

Entity type	Name	IP address	Port	Protocol
Virtual Server	Vserver-LB-1	10.102.29.13	53	DNS
Services	Service-DNS-1	10.102.29.14	53	DNS
	Service-DNS-2	10.102.29.15	53	DNS
	Service-DNS-3	10.102.29.16	53	DNS
Monitors	monitor-DNS-1	None	None	None

The following diagram shows the load balancing entities and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing DNS Servers Entity Model



To configure a basic DNS load balancing setup, see Setting Up Basic Load Balancing. Follow the procedures to create services and virtual servers of type DNS, naming the entities and setting the parameters using the values described in the previous table. When you configure a basic load balancing setup, the default ping monitor is bound to the services. For instructions on binding a DNS monitor to DNS services, you can also see Binding Monitors to Services.

The following procedure describes the steps to create a monitor that maps a domain name to the IP address based on a query.

To configure DNS monitors by using the command line interface

At the command prompt, type:

add lb monitor <monitorName> DNS -query <domainName> -queryType <**Address**|**ZONE**> -IPAddress <ipAddress>
Example

add lb monitor monitor-DNS-1 DNS -query www.citrix.com -queryType Address -IPAddress 10.102.29.66

add lb monitor monitor-DNS-2 DNS -query www.citrix2.com -queryType Address -IPAddress 1000:0000:0000:0000:0005:0600:700a::888b-888d

To configure DNS monitors by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Create a monitor of type DNS, and in Special Parameters, specify a query and query type.

Load Balancing Domain-Name Based Services

Aug 06, 2017

When you create a service for load balancing, you can provide an IP address. Alternatively, you can create a server using a domain name. The server name (domain name) can be resolved using an IPv4 or IPv6 name server, or by adding an authoritative DNS record (A record for IPv4 or AAAA record for IPv6) to the NetScaler configuration.

When you configure services with domain names instead of IP addresses, and if the name server resolves the domain name to a new IP address, the monitor bound to the service runs a health check on the new IP address, and updates the service IP address only when the IP address is found to be healthy. The monitor could be the default monitor bound to the service or you can bind any other supported monitor. It probes the service at regular intervals defined in the monitor parameters. If the domain name resolves to a new IP address, the monitor sends a fresh probe to check the health of the service. All subsequent probes are at the predefined interval.

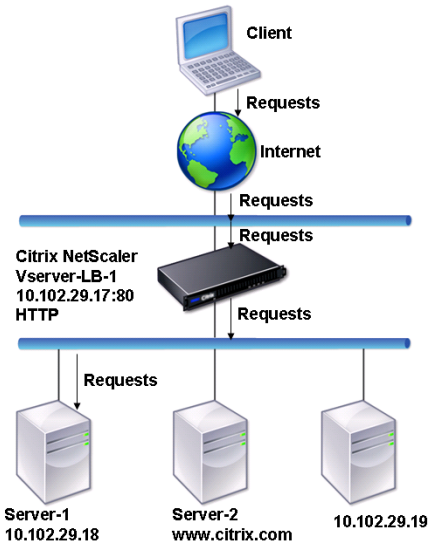
Note: When you change the IP address of a server, the corresponding service is marked down for the first client request. The name server resolves the service IP address to the changed IP address for the next request, and the service is marked UP.

Domain-name based services have the following restrictions:

- The maximum domain name length is 255 characters.
- The Maximum Client parameter is used to configure a service that represents the domain name-based server. For example, a maxClient of 1000 is set for the services bound to a virtual server. When the connection count at the virtual server reaches 2000, the DNS resolver changes the IP address of the services. However, because the connection counter on the service is not reset, the virtual server cannot take any new connections until all the old connections are closed.
- When the IP address of the service changes, persistence is difficult to maintain.
- If the domain name resolution fails due to a timeout, the appliance uses the old information (IP address).
- When monitoring detects that a service is down, the appliance performs a DNS resolution on the service (representing the domain name-based server) to obtain a new IP address.
- Statistics are collected on a service and are not reset when the IP address changes.
- If a DNS resolution returns a code of “name error” (3), the appliance marks the service down and changes the IP address to zero.

When the appliance receives a request for a service, it selects the target service. This way, the appliance balances load on your services. The following diagram describes the topology of a load balancing configuration that load balances a group of domain-name based servers (DBS).

Figure 1. Basic Load Balancing Topology for DBS Servers



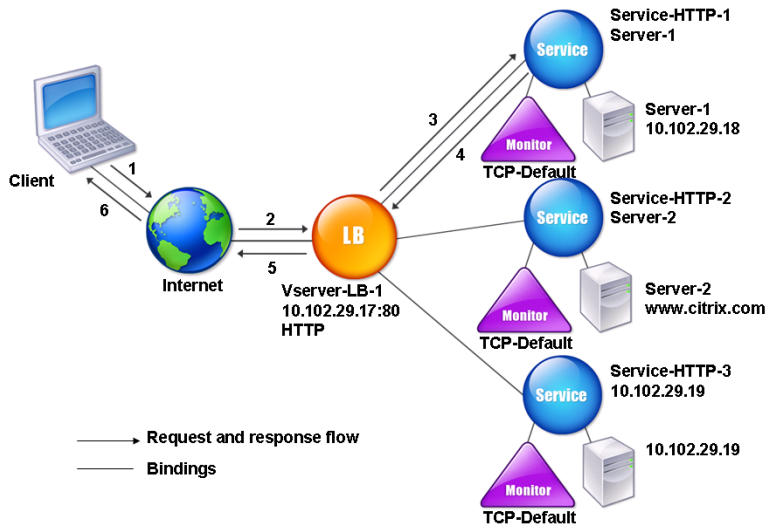
The services Service-HTTP-1, Service-HTTP-2, and Service-HTTP-3 are bound to the virtual server Vserver-LB-1. The vserver Vserver-LB-1 uses the least connection load balancing method to choose the service. The IP address of the service is resolved using the name server Vserver-LB-2.

The following table lists the names and values of the basic entities configured on the appliance.

Entity type	Name	IP address	Port	Protocol
Virtual Server	Vserver-LB-1	10.102.29.17	80	HTTP
	Vserver-LB-2	10.102.29.20	53	DNS
Servers	server-1	10.102.29.18	80	HTTP
	server-2	www.citrix.com	80	HTTP
Services	Service-HTTP-1	server-1	80	HTTP
	Service-HTTP-2	server-2	80	HTTP
	Service-HTTP-2	10.102.29.19	80	HTTP
Monitors	Default	None	None	None
Name Server	None	10.102.29.19	None	None

The following diagram shows the load balancing entities and the values of the parameters that need to be configured on the appliance.

Figure 2. Load Balancing DBS Servers Entity Model



To configure a basic load balancing setup, see Setting Up Basic Load Balancing. Create the services and virtual servers of type HTTP, and name the entities and set the parameters using the values described in the previous table.

You can add, remove, enable, and disable external name servers. You can create a name server by specifying its IP address, or you can configure an existing virtual server as the name server.

To add a name server by using the command line interface

At the command prompt, type:

add dns nameServer <dnsVserverName>
Example

add dns nameServer Vserver-LB-2

To add a name server by using the configuration utility

1. Navigate to **Traffic Management** > **DNS** > **Name Servers**.
2. Create a DNS name server of type DNS Virtual Server, and select a server from the DNS Virtual Server list.

You can also add an authoritative name server that resolves the domain name to an IP address.

> **Note**
>
> You can add a name server of type TCP, UDP or UDP_TCP to resolver DBS probes. However, if TCP and UDP name servers coexists, and a UDP name server receives a response with truncated bit, this response is not retried over TCP name server.

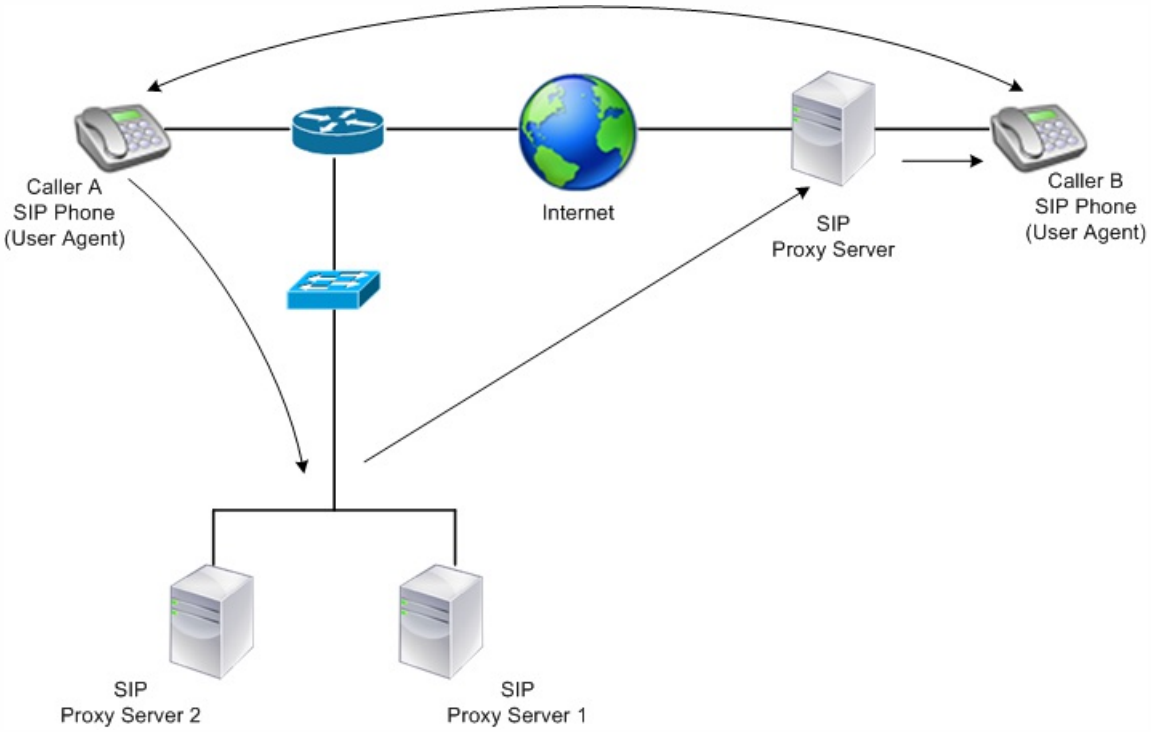
Load Balancing a Group of SIP Servers

Dec 09, 2014

The Session Initiation Protocol (SIP) is designed to initiate, manage, and terminate multimedia communications sessions. It has emerged as the standard for Internet telephony (VoIP). SIP messages can be transmitted over TCP or UDP. SIP messages are of two types: request messages and response messages.

The traffic in a SIP based communication system is routed through dedicated devices and applications (entities). In a multimedia communication session, these entities exchange messages. The following figure shows a basic SIP based communication system:

Figure 1. SIP Based Communication System



A NetScaler ADC enables you to load balance SIP messages over UDP or over TCP (including TLS). You can configure the NetScaler ADC to load balance SIP requests to a group of SIP proxy servers. To do so, you create a load balancing virtual server with the load balancing method and the type of persistence set to one of the following combinations:

- Call-ID hash load balancing method with no persistence setting
- Call-ID based persistence with least connection or round robin load balancing method
- Rule based persistence with least connection or round robin load balancing method

Also, by default, the NetScaler ADC appends RPORT to the via header of the SIP request, so that the server sends the response back to the source IP address and port from which the request originated.

Note: For load balancing to work, you must configure the SIP proxies so that they do not add private IP addresses or private domains to the SIP header/payload. SIP proxies must add to the SIP header a domain name that resolves to the IP address of the SIP virtual server. Also, the SIP proxies must communicate with a common database to share registration information.

Server Initiated Traffic

For SIP-server initiated outbound traffic, configure RNAT on the NetScaler ADC so that the private IP addresses used by the clients are translated into public IP addresses.
If you have configured SIP parameters that include the RNAT source or destination port, the appliance compares the values of the source and destination ports of the request packets with the RNAT source port and RNAT destination port. If one of the values matches, the appliance updates the VIA header with RPORT. The SIP response from the client then traverses the same path as the request.

For server-initiated SSL traffic, the NetScaler ADC uses a built-in certificate-key pair. If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the NetScaler internal service named **nsrnatsip-127.0.0.1-5061**.

Support for Policies and Expressions

The NetScaler default expressions language contains a number of expressions that operate on Session Initiation Protocol (SIP) connections. These expressions can be bound only to SIP based (sip_udp, sip_tcp or sip_ssl) virtual servers, and to global bind points. You can use these expressions in content switching, rate limiting, responder, and rewrite policies.
For more information, see SIP Expressions.

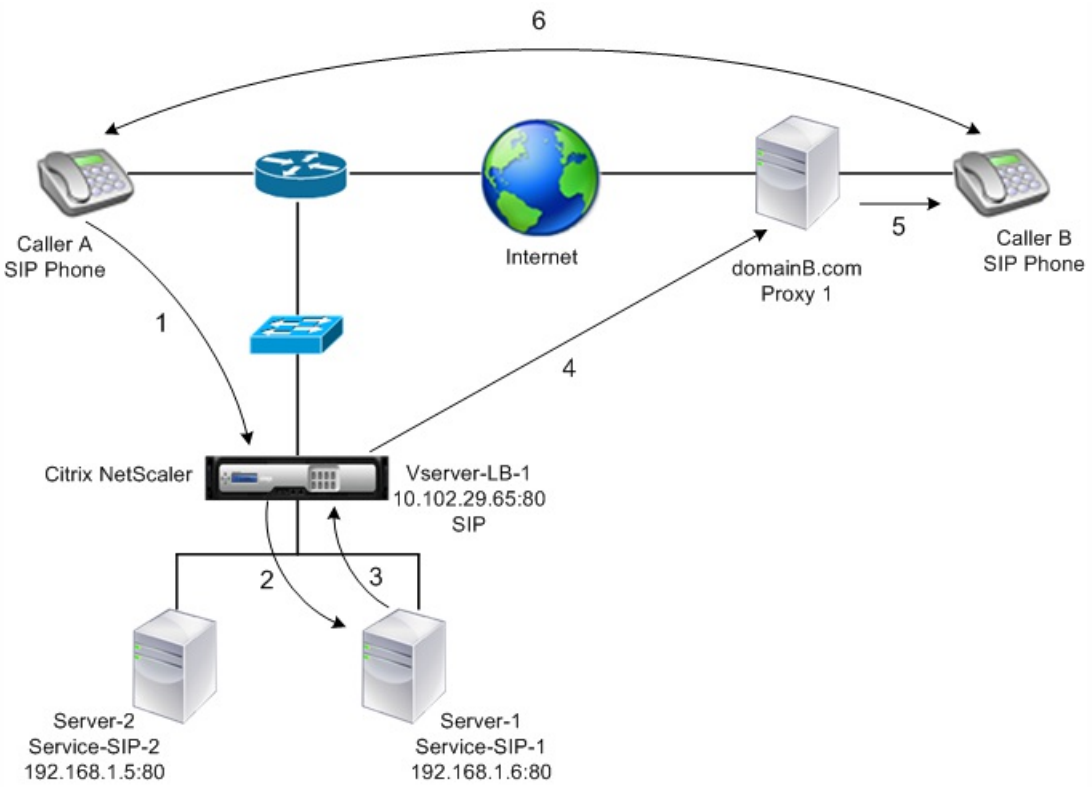
Configuring Load Balancing for SIP Signaling Traffic over TCP or UDP

The NetScaler ADC can load balance SIP servers that send requests over UDP or TCP, including TCP traffic secured by TLS. The ADC provides the following service types to load balance the SIP servers:

- SIP_UDP – Used when SIP servers send SIP messages over UDP.
- SIP_TCP – Used when SIP servers send SIP messages over TCP.
- SIP_SSL – Used to secure SIP signaling traffic over TCP by using SSL or TLS. The NetScaler ADC supports the following modes:
  - End-to-end TLS connection between the client, the ADC, and the SIP server.
  - TLS connection between the client and the ADC, and TCP connection between the ADC and the SIP server.
  - TCP connection between the client and the ADC, and TLS connection between the ADC and the SIP server.

The following figure shows the topology of a setup configured to load balance a group of SIP servers sending SIP messages over TCP or UDP.

Figure 2. SIP Load Balancing Topology



Entity type	Name	IP address	Port	Service type / Protocol
Virtual Server	Vserver-LB-1	10.102.29.65	80	SIP_UDP / SIP_TCP / SIP_SSL
Services	Service-SIP-1	192.168.1.6	80	SIP_UDP / SIP_TCP / SIP_SSL
	Service-SIP-2	192.168.1.5	80	SIP_UDP / SIP_TCP / SIP_SSL
Monitors	Default	None	80	SIP_UDP / SIP_TCP / SIP_SSL

Following is an overview of configuring basic load balancing for SIP traffic:

1. Configure services, and configure a virtual server for each type of SIP traffic that you want to load balance:
   - **SIP_UDP** – If you are load balancing the SIP traffic over UDP.
   - **SIP_TCP** – If you are load balancing the SIP traffic over TCP.
   - **SIP_SSL** – If you are load balancing and securing the SIP traffic over TCP.

   Note: If you use SIP_SSL, be sure to create an SSL certificate-key pair. For more information, see Adding a Certificate Key Pair.
2. Bind the services to the virtual servers.
3. If you want to monitor the states of the services with a monitor other than the default (**tcp-default**), create a custom monitor and bind it to the services. The NetScaler ADC provides two custom monitor types, **SIP-UDP** and **SIP-TCP**, for monitoring SIP services.
4. If using a SIP_SSL virtual server, bind an SSL certificate-key pair to the virtual server.

5. If you are using the NetSCaler ADC as the gateway for the SIP servers in your deployment, configure RNAT.
6. If you want to append RPORT to the SIP messages that are initiated from the SIP server, configure the SIP parameters.

To configure a basic load balancing setup for SIP traffic by using the command line interface

1. Create one or more services. At the command prompt, type:
   add service <name> <serverName> (SIP_UDP | SIP_TCP | SIP_SSL) <port>

   Example
   add service Service-SIP-UDP-1 192.0.2.5 SIP_UDP 80

2. Create as many virtual servers as necessary to handle the services that you created. The virtual server type must match the type of services that you will bind to it. At the command prompt, type:
   add lb vserver <name> <serverName> (SIP_UDP | SIP_TCP | SIP_SSL) <port>

   Example
   add lb vserver Vserver-LB-1 SIP_UDP 10.102.29.60 80

3. Bind each service to a virtual server. At the command prompt, type:
   bind lb vserver <name> <serverName>

   Example
   bind lb vserver Vserver-LB-1 Service-SIP-UDP-1

4. (Optional) Create a custom monitor of type SIP-UDP or SIP-TCP, and bind the monitor to the service. At the command prompt, type:
   add lb monitor <monitorName> <monitorType> [<interval>]

   bind lb monitor <monitorName> <ServiceName>

   Example
   add lb monitor mon1 sip-UDP -sipMethod REGISTER -sipuRI sip:mon@test.com -sipregURI sip:mon@test.com -respcode 200

   bind monitor mon1 Service-SIP-UDP-1

5. If you created a SIP_SSL virtual server, bind an SSL certificate key pair to the virtual server. At the command prompt, type: At the command prompt, type:
   bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName> -CA –skipCAName

   Example
   bind ssl vserver Vserver-LB-1 -certkeyName CertKey-SSL-1

6. Configure RNAT as required by your network topology. At the command prompt, type one of the following commands to create, respectively, an RNAT entry that uses a network address as the condition and a MIP or SNIP as the NAT IP address, an RNAT entry that uses a network address as the condition and a unique IP address as the NAT IP address, an RNAT entry that uses an ACL as the condition and a MIP or SNIP as the NAT IP address, or an RNAT entry that uses an ACL as a condition and a unique IP address as the NAT IP address:
   set rnat <IPAddress> <netmask>

   set rnat <IPAddress> <netmask> -natip <NATIPAddress>

set rnat <aclname> [-redirectPort <port>]

set rnat <aclname> [-redirectPort <port>] -natIP <NATIPAddress>

Example
set rnat 192.168.1.0 255.255.255.0 -natip 10.102.29.50

If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the NetScaler internal service named **nsrnatsip-127.0.0.1-5061**.

add ssl certKey <certkeyName> -cert <string> [-key <string>]

bind ssl service <serviceName> -certkeyName <string>

Example
add ssl certKey c1 -cert cert.epm -key key.ky

bind ssl service nsrnatsip-127.0.0.1-5061 -certkeyName c1

7. If you want to append RPORT to the SIP messages that the SIP server initiates, type the following command at the command prompt:
set lb sipParameters -rnatSrcPort <rnatSrcPort> -rnatDstPort<rnatDstPort> -retryDur <integer> -addRportVip <addRportVip> - sip503RateThreshold <sip503_rate_threshold_value>

Sample Configuration for load balancing the SIP traffic over UDP

> add service service-UDP-1 10.102.29.5 SIP_UDP 80

Done

> add lb vserver vserver-LB-1 SIP_UDP 10.102.29.60 80

Done

> bind lb vserver vserver-LB-1 service-UDP-1

Done

> add lb mon mon1 sip-udp -sipMethod REGISTER -sipuRI sip:mon@test.com -sipregURI sip:mon@test.com -respcode 200

Done

> bind mon mon1 service-UDP-1

Done

> set rnat 192.168.1.0 255.255.255.0

Done

> set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000 -addRportVip ENABLED -sip503RateThreshold 1000

Done

Sample Configuration for load balancing the SIP traffic over TCP

```
> add service service-TCP-1 10.102.29.5 SIP_TCP 80

Done

> add lb vserver vserver-LB-1 SIP_TCP 10.102.29.60 80

Done

> bind lb vserver vserver-LB-1 service-TCP-1

Done

> add lb mon mon1 sip-tcp -sipMethod REGISTER -sipuRI sip:mon@test.com -sipregURI sip:mon@test.com -respcode 200

Done

> bind mon mon1 service-TCP-1

Done

> set rnat 192.168.1.0 255.255.255.0

Done

> set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000 -addRportVip ENABLED -sip503RateThreshold
1000

Done
```

Sample Configuration for load balancing and securing SIP traffic over TCP

```
> add service service-SIP-SSL-1 10.102.29.5 SIP_SSL 80

Done

> add lb vserver vserver-LB-1 SIP_SSL 10.102.29.60 80

Done

> bind lb vserver vserver-LB-1 service-SIP-SSL

Done

> add lb mon mon1 sip-tCP -sipMethod REGISTER -sipuRI sip:mon@test.com -sipregURI sip:mon@test.com -respcode 200

Done

> bind mon mon1 service-SIP-SSL

Done

> bind ssl vserver Vserver-LB-1 -certkeyName CertKey-SSL-1

Done
```

```
> set rnat 192.168.1.0 255.255.255.0

Done

> set lb sipParameters -rnatSrcPort 5060 -rnatDstPort 5060 -retryDur 1000 -addRportVip ENABLED -sip503RateThreshold 1000

Done
```

To configure a basic load balancing setup for SIP traffic by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and add a virtual server of type SIP_UDP, SIP_TCP, or SIP_SSL.
2. Click the Service section, and add a service of type SIP_UDP, SIP_TCP, or SIP_SSL.
3. (Optional) Click the Monitor section, and add a monitor of type: SIP-UDP or SIP-TCP.
4. Bind the monitor to the service, and bind the service to the virtual server.
5. If you created a SIP_SSL virtual server, bind an SSL certificate key pair to the virtual server. Click the Certificates section, and bind a certificate key pair to the virtual server.
6. Configure RNAT as required by your network topology. To configure RNAT:
   1. Navigate to System > Network > Routes.
   2. On the Routes page, click the RNAT tab.
   3. In the details pane, click Configure RNAT.
   4. In the Configure RNAT dialog box, do one of the following:
      - If you want to use the network address as a condition for creating an RNAT entry, click Network and set the following parameters:
        - Network
        - Netmask
      - If you want to use an extended ACL as a condition for creating an RNAT entry, click ACL and set the following parameters:
        - ACL Name
        - Redirect Port
   5. To set a MIP or SNIP address as a NAT IP address, skip to step 7.
   6. To set a unique IP address as a NAT IP, in the Available NAT IP (s) list, select the IP address that you want to set as the NAT IP, and then click Add. The NAT IP you selected appears in the Configured NAT IP(s) list.
   7. Click Create, and then click Close.

   If you want to use a custom certificate-key pair, bind the custom certificate-key pair to the NetScaler internal service named **nsrnatsip-127.0.0.1-5061**. To bind the pair:

   1. Navigate to Traffic Management > Load Balancing > Services and click the Internal Services tab.
   2. Select nsrnatsip-127.0.0.1-5061 and click **Edit**.
   3. Click the **Certificates** section and bind a certificate key pair to the internal service.
7. If you want to append RPORT to the SIP messages that the SIP server initiates, configure the SIP parameters. Navigate to Traffic Management > Load Balancing and click Change SIP settings, set the various SIP parameters.

SIP Expression and Policy Example: Compression Enabled in Client Requests

A NetScaler ADC cannot process compressed client SIP requests, so the client SIP request fails.

You can configure a responder policy that intercepts the SIP NEGOTIATE message from the client and looks for the compression header. If the message includes a compression header, the policy responds with "400 Bad Request," so that

the client resends the request without compressing it.

At the command prompt, type the following commands to create the responder policy:

```
> add responder action sipaction1 respondwith q{"SIP/2.0 400 Bad Request\r\n\r\n"}

Done.

> add responder policy sippol1

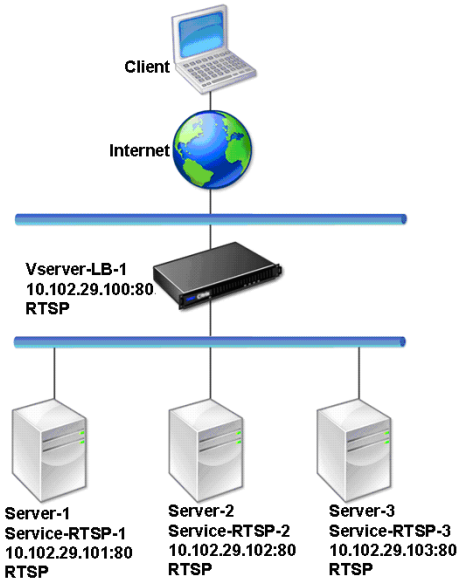
> add responder policy sippol1 "SIP.REQ.METHOD.EQ(\"NEGOTIATE\")&&SIP.REQ.HEADER(\"Compression\").EXISTS" sipaction1
```

Load Balancing RTSP Servers

Feb 13, 2017

The NetScaler appliance can balance load on RTSP servers to improve the performance of audio and video streams over networks. The following diagram describes the topology of an load balancing setup configured to load balance a group of RTSP servers.

Figure 1. Load Balancing Topology for RTSP

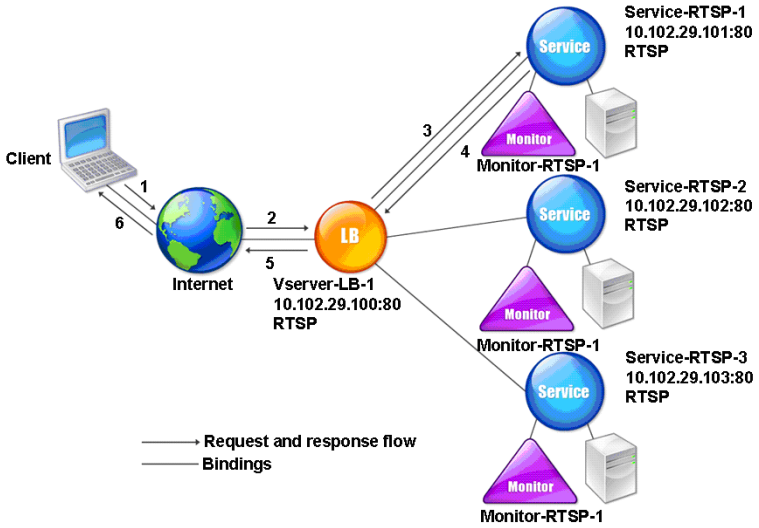


In the example, the services Service-RTSP-1, Service-RTSP-2, and Service-RTSP-3 are bound to the virtual server Vserver-LB-1. The following table lists the names and values of the example entities.

Entity type	Name	IP address	Port	Protocol
Virtual Server	Vserver-LB-1	10.102.29.100	554	RTSP
Services	Service-RTSP-1	10.102.29.101	554	RTSP
	Service-RTSP-2	10.102.29.102	554	RTSP
	Service-RTSP-3	10.102.29.103	554	RTSP
Monitors	Monitor-RTSP-1	None	554	RTSP

The following diagram shows the load balancing entities used in RTSP configuration.

Figure 2. Load Balancing RTSP Servers Entity Model



To configure a basic load balancing setup for RTSP servers, see Setting Up Basic Load Balancing. Create services and virtual servers of type RTSP. When you configure a basic load balancing setup, the default TCP-default monitor is bound to the services. To bind an RTSP monitor to these services, see Binding Monitors to Services. The following procedure describes how create a monitor that checks RTSP servers.

To configure RTSP monitors by using the command line interface

At the command prompt, type:

add lb monitor <monitorName> <type>

Example

add lb monitor Monitor-RTSP-1 RTSP

To configure RTSP monitors by using the configuration utility

Navigate to Traffic Management > Load Balancing > Monitors, and create a monitor of type RTSP.

Load Balancing of Remote Desktop Protocol (RDP) Servers

Jun 27, 2017

Remote Desktop Protocol (RDP) is a multichannel-capable protocol that allows for separate virtual channels for carrying presentation data, serial device communication, licensing information, highly encrypted data (keyboard and mouse activity), and so on.

RDP is used for providing a graphical user interface to another computer on the network. RDP is used with Windows terminal servers for providing fast access with almost real-time transmission of mouse movements and key presses even over low-bandwidth connections.

When multiple terminal servers are deployed to provide remote desktop services, the NetScaler appliance provides load balancing of the terminal servers (Windows 2003 and 2008 Server Enterprise Editions). In some cases, a user who is accessing an application remotely may want to leave the application running on the remote machine but shut down the local machine. The user therefore closes the local application without logging out of the remote application. After reconnecting to the remote machine, the user should be able to continue with the remote application. To provide this functionality, the NetScaler RDP implementation honors the routing token (cookie) set by the Terminal Services Session Directory or Broker so that the client can reconnect to the same terminal server to which it was connected previously. The Session Directory, implemented on Windows 2003 Terminal Server, is referred to as Broker on Windows 2008 Terminal Server.

When a TCP connection is established between the client and the load balancing virtual server, the NetScaler applies the specified load balancing method and forwards the request to one of the terminal servers. The terminal server checks the session directory to determine whether the client has a session running on any other terminal server in the domain.

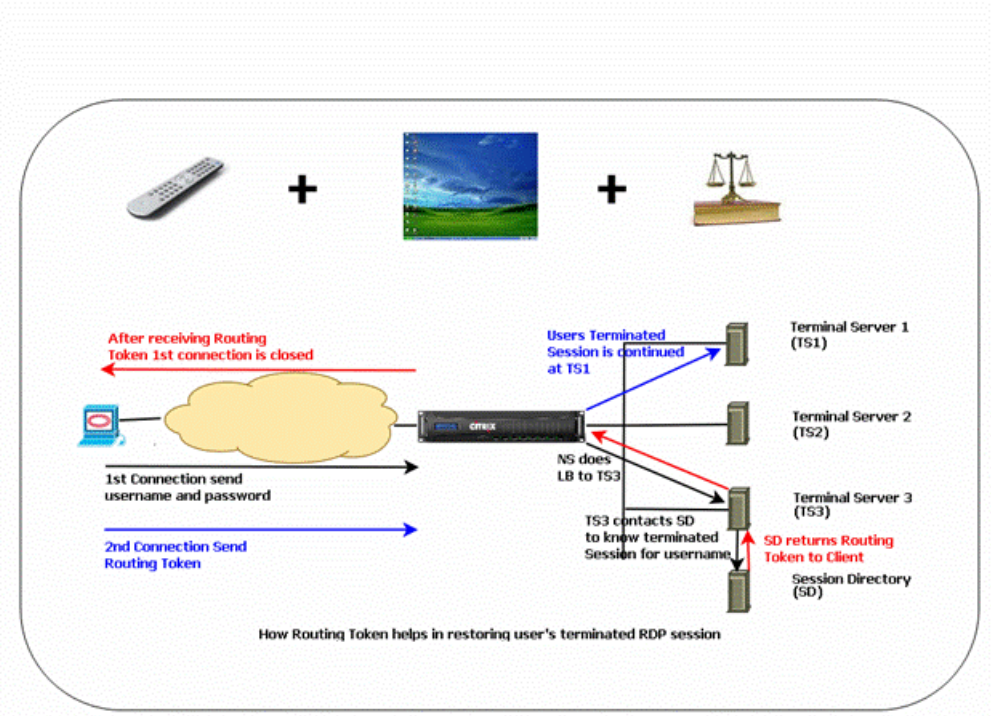
If there is no active session on any other terminal server, the terminal server responds by serving the client request, and the NetScaler forwards the response to the client.

If there is an active session on any other terminal server, the terminal server that receives the request inserts a cookie (referred to as routing token) with the details of the active session and returns the packets to the NetScaler, which returns the packet to the client. The server closes the connection with the client. When the client retries to connect, the NetScaler reads the cookie information and forwards the packet to the terminal server on which the client has an active session.

The user on the client machine experiences a continuation of the service and does not have to take any specific action.

Note: The Windows Session Directory feature requires the Remote Desktop client that was first released with Windows XP. If a session with a Windows 2000 or Windows NT 4.0 Terminal Server client is disconnected and the client reconnects, the server with which the connection is established is selected by the load balancing algorithm.
The following diagram describes RDP load balancing.

Figure 1. Load Balancing Topology for RDP



Note

- When an RDP service is configured, persistence is automatically maintained by using a routing token. You need not enable persistence explicitly.
- The NetScaler appliance supports only IP-based cookies.

Ensure that the disconnected RDP sessions are cleared on the terminal servers at the backend to avoid flapping between two terminal servers when an RDP session is disconnected without logging out. For more information, see http://technet.microsoft.com/en-us/library/cc758177(WS.10).aspx#BKMK_2

When you add an RDP service, by default, NetScaler adds a monitor of the type TCP and binds it to the service. The default monitor is a simple TCP monitor that checks whether or not a listening process exists at the 3389 port on the server specified for the RDP service. If there is a listening process at 3389, NetScaler marks this service as UP and if there is no listening process, it marks the service as DOWN.

For more efficient monitoring of an RDP service, in addition to the default monitor, you can configure a script monitor that is meant for the RDP protocol. When you configure the scripting monitor, the NetScaler opens a TCP connection to the specified server and sends an RDP packet. The monitor marks the service as UP only if it receives a confirmation of the connection from the physical server. Therefore, from the scripting monitor, the NetScaler can know whether the RDP service is ready to service a request.

The monitor is a user-type monitor and the script is located on the NetScaler at /nsconfig/monitors/nsrdp.pl. When you configure the user monitor, the NetScaler runs the script automatically. To configure the scripting monitor, add the monitor and bind it to the RDP service.

To configure RDP load balancing, create services of type RDP and bind them to an RDP virtual server.

To configure RDP load balancing services by using the command line interface

At the command prompt, type the following commands to configure an RDP load balancing setup and verify the configuration:

add service <name>@ <serverName> <serviceType> <port>

Note: Repeat the above command to add more services.
Example

```
> add service ser1 10.102.27.182 RDP 3389
Done
> add service ser2 10.102.27.183 RDP 3389
Done
>show service ser1
ser1 (10.102. 27.182:3389) - RDP
      State: UP
…
  Server Name: 10.102.27.182
  Server ID : 0    Monitor Threshold : 0
      Down state flush: ENABLED
…
1)     Monitor Name: tcp-default
            State: UP       Weight: 1
…
            Response Time: 4.152 millisec
 Done
```

To configure RDP load balancing services by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, and create services of type RDP.

To configure an RDP load balancing virtual server by using the command line interface

At the command prompt, type the following commands to configure an RDP load balancing virtual server and verify the configuration:

- add lb vserver <name>@ <serviceType> <ipAddress> <port>
- bind lb vserver <name>@ <serviceName>

  Bind all the RDP services to be load balanced to the virtual server.

Example

This example has two RDP services bound to the RDP virtual server.

```
> add lb vs v1 rdP 10.102.27.186 3389
Done

> bind lb vs v1 ser1
```

```
service "ser1" bound
> bind lb vs v1 ser2
service "ser2" bound
Done

>sh lb vs v1
v1 (10.102.27.186:3389) - RDP   Type: ADDRESS
State: UP
…
No. of Bound Services :  2 (Total)      2 (Active)
Configured Method: LEASTCONNECTION
  Current Method: Round Robin, Reason: A new service is bound
Mode: IP
Persistence: NONE
  L2Conn: OFF

1) ser1 (10.102.27.182: 3389) - RDPState: UP   Weight: 1
2) ser2 (10.102.27.183: 3389) - RDPState: UP   Weight: 1
Done
```

To configure an RDP load balancing virtual server by using the configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Servers, create a virtual server of type RDP, and bind RDP services to this virtual server.

To configure a scripting monitor for RDP services by using the command line interface

At the command prompt, type the following commands:

- add lb monitor <monitorName> USER -scriptName nsrdp.pl
- bind lb monitor <monitorName> <rdpServiceName>

Example

```
add service ser1 10.102.27.182 RDP 3389
add lb monitor RDP_MON USER -scriptName nsrdp.pl
bind lb monitor RDP_MON ser1
```

To configure a scripting monitor for RDP services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors, and create a monitor of type USER.
2. In Special Parameters, in the Script Name list, select nsrdp.pl, and then bind this monitor to an RDP service.

Use Case 1: SMPP Load Balancing

Feb 17, 2016

Millions of short messages are exchanged daily between individuals and value-added service providers, such as banks, advertisers, and directory services, by using the short message peer to peer (SMPP) protocol. Often, message delivery is delayed because servers are overloaded and traffic is not optimally distributed among the servers. The NetScaler ADC supports SMPP load balancing and provides optimal distribution of messages across your servers, preventing poor performance and outages.

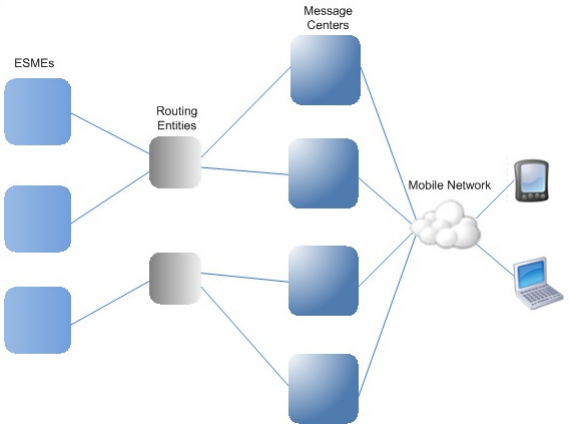
The NetScaler ADC performs load balancing on the server side when messages are received from clients and on the client side when messages are received from servers.

Load balancing of SMPP messages by the NetScaler ADC provides the following benefits:

- Better load distribution on servers, which translates to faster response time to end users
- Server health monitoring and better failover capabilities
- Quick and easy addition of new servers (message centers) without changing the client configuration
- High availability

Introduction to SMPP

SMPP is an application layer protocol for transfer of short messages between External Short Message Entities (ESME), Routing Entities (RE) and Message Centers (MC) over long-lived TCP connections. It is used for sending short message service (SMS) messages between friends, contacts, and third parties such as banks (mobile banking), advertisers (mobile commerce), and directory services. Messages from an ESME (non-mobile entity) arrive at the MC, which distributes them to short message entities (SMEs) such as mobile phones. SMPP is also used by SMEs to send short messages to third parties (for example, for purchase of products, bill payment, and funds transfer). These messages arrive at the MC and are forwarded to the destination MC or ESME.
The following diagram shows the different SMPP entities: ESMEs, REs, and MCs, in a mobile network.



Architecture Overview of the Different SMPP Entities in a Mobile Network

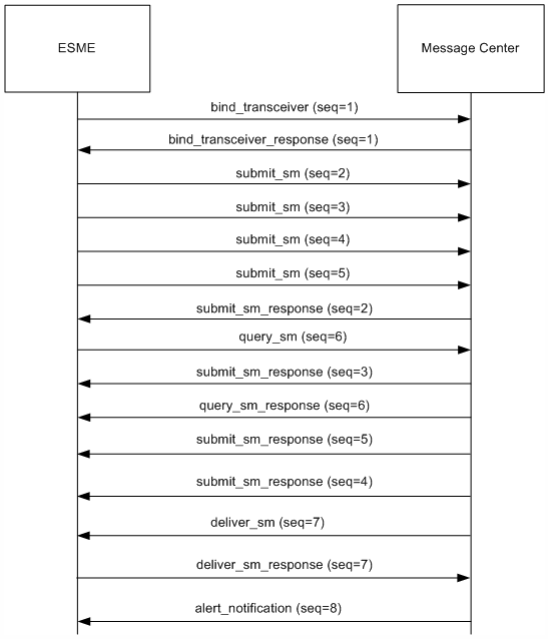
Note: The terms client and ESME are used interchangeably throughout the document.
An ESME (client) opens a connection to the MC in one of the three modes: as a transmitter, a receiver, or a transceiver. As a transmitter, it can only submit messages for delivery. As a receiver, it can only receive messages. As a transceiver, the ESME can both submit and receives messages. The ESME sends the MC one of the three messages (also known as PDUs): bind_transmitter, bind_receiver, or bind_transceiver. The MC responds with a bind_transmitter_resp, bind_receiver_resp, or bind_transceiver_resp, as appropriate for the request.

After the connection is established, the ESME can, depending on the mode in which it is bound to the MC, send a submit_sm or data_sm message, receive a deliver_sm or data_sm message, or send and receive any of these types of messages. The ESME can also send ancillary messages, such as query_sm, replace_sm, and cancel_sm, to query the status of an earlier message delivery, replace an earlier message with a new message, or cancel an undelivered message.

If a message is not delivered because an ESME is not available or a mobile subscriber is not online, the message is queued. Later, when the MC detects that the mobile subscriber is now reachable, it sends an alert_notification PDU to the ESME over a receiver or transceiver session, requesting delivery of any queued messages.

Each request PDU has a unique sequence number. The response PDU has the same sequence number as the original request. Because message exchange over SMPP can be in asynchronous mode, an ESME or an MC can send multiple requests at a time. The sequence number plays a crucial role in returning the response in the same SMPP session. In other words, the sequence number makes request and response matching possible.

The following diagram shows how the traffic flow uses the various PDUs when the ESME binds as a transceiver.



Limitation

The NetScaler appliance does not support outbind operations. That is, a message center cannot initiate an SMPP session with an ESME through the NetScaler appliance.

How SMPP Load Balancing Works on the NetScaler ADC

An ESME (client) sends a bind message to open a connection to the NetScaler ADC. The ADC authenticates each ESME and, if successful, responds with an appropriate message. The NetScaler ADC establishes a connection with each message center and load balances all the messages among these message centers. When the ADC receives a message from a client, it reuses an open connection to the message center or sends a bind request to a message center if an open connection is not available.

The ADC can load balance messages originating from the clients and from the servers. It can monitor the health of the message centers and handle concatenated messages. It also provides content switching support for the message centers.

Messages Originating from the ESMEs

Each ESME must be added as a user on the NetScaler ADC for authentication. The client establishes a TCP connection with an SMPP virtual server configured on the ADC by sending a bind request. The ADC authenticates the client and, if successful, parses the bind message. The ADC then sends the request to the message center selected by the configured load balancing method. If a connection to the message center is not available for reuse, the ADC opens a TCP connection with the message center by sending a new bind request to the message center.
Before forwarding the response (submit_sm_resp or data_sm_resp) from the message center to the client, the ADC adds a custom server ID to the message ID to identify the message center for ancillary operations, such as query, replace, or cancel requests for a message, by the client. Requests from other clients are load balanced in the same way.

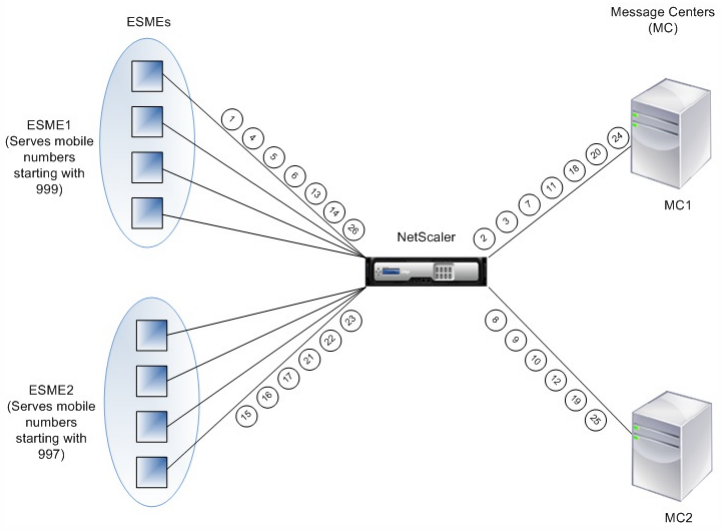
In the original bind request, a client specifies the address range that it can serve. This range is used for forwarding deliver_sm or data_sm messages from the message centers to the clients.

Messages Originating from a Message Center

ESMEs that can handle a specific address range are grouped into a cluster. All the nodes in a cluster provide the same credentials. Within a cluster, only the round robin method is used for load balancing. To deliver mobile originated (MO) messages, the message center sends a deliver_sm message to the NetScaler ADC. If a cluster that can serve the destination address range (for example, numbers starting with 998) is bound to the ADC, it selects that cluster, and then load balances the message among the ESME nodes in that cluster.

If an ESME that can serve deliver_sm messages for the address range is not bound to the ADC, and message queuing is enabled, the message is queued until such a client binds to the ADC in a receiver or transceiver mode. You can specify the size of the queue.

The following diagram illustrates the internal flow of PDUs between ESMEs, NetScaler ADC, and the message centers. For simplicity, only two ESMEs and two message centers are shown.



Flow of messages (PDUs):

1. ESME1 sends bind request to NetScaler
2. NetScaler sends bind request to MC1
3. MC1 sends bind response to NetScaler
4. NetScaler sends bind response to ESME1
5. ESME1 sends submit_sm(1) to NetScaler
6. ESME1 sends submit_sm(2) to NetScaler
7. NetScaler forwards submit_sm(1) to MC1
8. NetScaler sends bind request to MC2
9. MC2 sends bind response to NetScaler
10. NetScaler forwards submit_sm(2) to MC2
11. MC1 sends submit_sm_resp(1) to NetScaler
12. MC2 sends submit_sm_resp(2) to NetScaler
13. NetScaler forwards submit_sm_resp(1) to ESME1
14. NetScaler forwards submit_sm_resp(2) to ESME1
15. ESME2 sends bind request to NetScaler
16. NetScaler sends bind response to ESME2
17. ESME2 sends submit_sm(3) to NetScaler
18. NetScaler forwards submit_sm(3) to MC1
19. MC2 sends deliver_sm to NetScaler (ESME2 serves the address range specified in the message)
20. MC1 sends submit_sm_resp(3) to NetScaler
21. NetScaler forwards submit_sm_resp(3) to ESME2
22. NetScaler forwards deliver_sm to ESME2
23. ESME2 sends deliver_sm_resp to NetScaler
24. MC1 sends alert_notification to NetScaler (ESME1 serves the address range specified in the message)
25. NetScaler forwards deliver_sm_resp to MC2
26. NetScaler forwards the alert_notification to ESME1

Health Monitoring of Message Centers

By default, a TCP_default monitor is bound to an SMPP service, but you can bind a custom monitor of type SMPP. The custom monitor opens a TCP connection to the message center and sends an enquire_link packet. Depending on the success or failure of the probe, the service is marked UP or DOWN.

Content Switching on Message Centers

Message centers can accept multiple connections (or bind requests) from ESMEs. You can configure the NetScaler ADC to content switch these requests on the basis of the SMPP bind parameters. Following are some common expressions for configuring methods to select a message center:

- Based on the address range: In the following sample expression, the ADC selects a specific message center if the address range starts at 988.
  Example

  ```
  SMPP.BINDINFO.ADDRESS_RANGE.CONTAINS(\"^988\")
  ```

- Based the ESME ID: In the following sample expression, the ADC selects a specific message center if the ESME ID equals ESME1.
  Example

  ```
  SMPP.BINDINFO.SYSTEM_ID.EQ("ESME1")
  ```

- Based on the ESME type: In the following sample expression, the ADC selects a specific message center if the ESME type is VMS. VMS stands for voice mail system.
  Example

  ```
  SMPP.BINDINFO.SYSTEM_TYPE.EQ("VMS")
  ```

- Based on the type of number (TON) of the ESME: In the following sample expression, the ADC selects a specific message center if TON equals 1 (1 stands for an international number.)
  Example

  ```
  SMPP.BINDINFO.ADDR_TON.EQ(1)
  ```

- Based on the number plan indicator (NPI) of the ESME: In the following sample expression, the ADC selects a specific message center if NPI equals 0 (0 stands for an unknown connection.)

Example

SMPP.BINDINFO.ADDR_NPI.EQ(0)

- Based on the bind type: In the following sample expression, the ADC selects a specific message center if the bind type is TRANSCEIVER. (A transceiver can send and receive messages.)
  Example

  SMPP.BINDINFO.TYPE.EQ(TRANSCEIVER)

Concatenated Message Handling

An SMS can hold a maximum of 140 bytes. Longer messages must be broken down into smaller parts. If the destination mobile is capable, the messages are combined and delivered as one long SMS. The NetScaler ADC forwards the fragments of a message to the same message center. Each message contains a reference number, a sequence number, and the total number of fragments. The reference number is the same for each fragment of a long message. The sequence number specifies that position of the particular fragment in the complete message. After all the fragments are received, the ESME combines the fragments into one long message and delivers the message to the mobile subscriber.

If a client disconnects from an active connection, the connection to the message center is not closed. It is reused for requests from other clients.

Limitation

Message IDs, from the message center, longer than 59 bytes are not supported. If the message ID length returned by the message center is more than 59 bytes, ancillary operations fail and the NetScaler ADC responds with an error message.

Configuring SMPP Load Balancing on the NetScaler ADC

Perform the following tasks to configure SMPP load balancing on the ADC:

1. Add an SMPP user. The ADC authenticates the user before it accepts a bind request from the user. The user is typically an ESME.
2. Add a load balancing virtual server, specifying the protocol as SMPP.
3. Add a service, specifying the protocol as SMPP, and a custom server ID that is unique for each server. Bind the service to the load balancing virtual server created earlier.
4. Optionally, create a service group and add services to the service group.
5. Optionally, add a monitor of type SMPP-ECV and bind it to the service. A TCP-default monitor is bound by default.
6. Set the SMPP parameters, such as client mode and message queue.

To configure SMPP load balancing by using the command line

At the command prompt, type:

- add smpp user <username> -password <password>
- add service <name> <IP> SMPP <port> –customserverID <customserverID>
- add lb vserver <name> <IP> SMPP <port>
- bind lb vserver <name> <service name>
- set smpp param

Example

```
add smpp user smppclient1 -password c03ebb540695b6110eb31172f32245a1 -encrypted -encryptmethod ENCMTHD_2
add smpp user smppclient2 -password c03ebb540695b6110eb31172f32245a1 -encrypted -encryptmethod ENCMTHD_2
add service smmpsvc 10.102.84.140 SMPP 2775 -gslb NONE -maxClient 0 -maxReq 0 -cip DISABLED -usip NO -useproxyport YES -sp ON -cltTimeout 180 -svrTimeout 360 -CustomServerID ab -CKA N
add service smmpsvc2 10.102.81.175 SMPP 2775 -gslb NONE -maxClient 0 -maxReq 0 -cip DISABLED -usip NO -useproxyport YES -sp ON -cltTimeout 180 -svrTimeout 360 -CustomServerID xy -CKA
add lb vserver smppvs SMPP 10.102.239.179 2775 -persistenceType NONE -cltTimeout 180
bind lb vserver smppvs smmpsvc2
bind lb vserver smppvs smmpsvc
set smpp param -addrrange "\\d*"
```

To configure SMPP load balancing by using the configuration utility

1. Navigate to System > User Administration > SMPP Users, and add an SMPP user.
2. Navigate to Traffic Management > Load Balancing > Configure SMPP Parameters, and set the parameters as required by your deployment.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers, and add a virtual server of type SMPP.
4. Click in the Service section, add a service of type SMPP, and specify a Server ID.

Use Case 2: Configuring Rule Based Persistence Based on a Name-Value Pair in a TCP Byte Stream

Jun 08, 2015

Some protocols transmit name-value pairs in a TCP byte stream. The protocol in the TCP byte stream in this example is the Financial Information eXchange (FIX) protocol. In its traditional, non-XML implementation, the FIX protocol enables two hosts communicating over a network to exchange business or trade-related information as a list of name-value pairs (called "FIX fields"). The field format is <tag>=<value><delimiter>. This traditional tag-value format makes the FIX protocol ideal for the use case.

The tag in a FIX field is a numeric identifier that indicates the meaning of the field. For example, the tag 35 indicates the message type. The value after the equal sign holds a specific meaning for the given tag and is associated with a data type. For example, a value of A for the tag 35 indicates that the message is a logon message. The delimiter is the nonprinting "Start of Header" (SOH) ASCII character (0x01), which is the caret symbol (^). Each field is also assigned a name. For example, the field with tag 35 is the msgType field. Following is an example of a logon message.

8=FIX.4.1 9=61 35=A 49=INVMGR 56=BRKR 34=1 52=20000426-12:05:06 98=0 108=30 10=157

Your choice of persistence type for a tag-value list such as the one shown above is determined by the options that are available to you for extracting a particular string from the list. Token-based persistence methods require you to specify the offset and length of the token that you want to extract from the payload. The FIX protocol does not allow you to do that, because the offset of a given field and the length of its value can vary from one message to another (depending on the message type, the preceding fields, and the lengths of the preceding values) and from one implementation to another (depending on whether custom fields have been defined). Such variations make it impossible to predict the exact offset of a given field or to specify the length of the value that is to be extracted as the token. In this case, therefore, rule based persistence is the preferred persistence type.

Assume that a virtual server fixlb1 is load balancing TCP connections to a farm of servers hosting instances of a FIX-enabled application, and that you want to configure persistence for connections on the basis of the value of the SenderCompID field, which identifies the firm sending the message. The tag for this FIX field is 49 (shown in the earlier logon message example).

To configure rule based persistence for the load balancing virtual server, set the persistence type for the load balancing virtual server to RULE and configure the rule parameter with an expression. The expression must be one that extracts the portion of the TCP payload in which you expect to find the SenderCompID field, typecasts the resulting string to a name-value list based on the delimiters, and then extracts the value of the SenderCompID field (tag 49), as follows:

```
set lb vserver fixlb1 -persistenceType RULE -rule
"CLIENT.TCP.PAYLOAD(300).TYPECAST_NVLIST_T('=','^').VALUE(\"49\")"
```

Note: Backslash characters have been used in the expression because this is a CLI command. If you are using the configuration utility, do not enter the backslash characters.
If the client sends a FIX message that contains the name-value list in the earlier logon message example, the expression extracts the value INVMGR, and the NetScaler appliance creates a persistence session based on this value.

The argument to the PAYLOAD() function can be as large as you deem is necessary to include the SenderCompID field in the string extracted by the function. Optionally, you can use the SET_TEXT_MODE(IGNORECASE) function if you want

the appliance to ignore case when extracting the value of the field, and the HASH function to create a persistence session based on a hash of the extracted value. The following expression uses the SET_TEXT_MODE(IGNORECASE) and HASH functions:

```
CLIENT.TCP.PAYLOAD(500).TYPECAST_NVLIST_T('=','^').SET_TEXT_MODE(IGNORECASE).VALUE("49").HASH
```

Following are more examples of rules that you can use to configure persistence for FIX connections (replace <tag> with the tag of the field whose value you want to extract):

- To extract the value of any FIX field in the first 300 bytes of the TCP payload, you can use the expression CLIENT.TCP.PAYLOAD(300).BEFORE_STR("^").AFTER_STR("<tag>=").
- To extract a string that is 20 bytes long at offset 80, cast the string to a name-value list, and then extract the value of the field that you want, use the expression CLIENT.TCP.PAYLOAD(100).SUBSTR(80,20).TYPECAST_NVLIST_T('=','^').VALUE("<tag>").
- To extract the first 100 bytes of the TCP payload, cast the string to a name-value list, and extract the value of the third occurrence of the field that you want, use the expression CLIENT.TCP.PAYLOAD(100).TYPECAST_NVLIST_T('=','^').VALUE("<tag>",2).
  Note: If the second argument that is passed to the VALUE() function is n, the appliance extracts the value of the $(n+1)^{th}$ instance of the field because the count starts from zero (0).

Following are more examples of rules that you can use to configure persistence. Only the payload-based expressions can evaluate data being transmitted through the FIX protocol. The other expressions are more general expressions for configuring persistence based on lower networking protocols.

- CLIENT.TCP.PAYLOAD(100)
- CLIENT.TCP.PAYLOAD(100).HASH
- CLIENT.TCP.PAYLOAD(100).SUBSTR(5,10)
- CLIENT.TCP.SRCPORT
- CLIENT.TCP.DSTPORT
- CLIENT.IP.SRC
- CLIENT.IP.DST
- CLIENT.IP.SRC.GET4
- CLIENT.IP.DST.GET4
- CLIENT.ETHER.SRCMAC.GET6
- CLIENT.ETHER.DSTMAC.GET5
- CLIENT.VLAN.ID

Use Case 3: Configuring Load Balancing in Direct Server Return Mode

Jun 20, 2017

Load balancing in direct server return (DSR) mode allows the server to respond to clients directly by using a return path that does not flow through the NetScaler appliance. In DSR mode, however, the appliance can continue to perform health checks on services. In a high-data volume environment, sending server traffic directly to the client in DSR mode increases the overall packet handling capacity of the appliance because the packets do not flow through the appliance.

DSR mode has the following features and limitations:

- It supports one-arm mode and inline mode.
- The appliance ages out sessions based on idle timeout.
- Because the appliance does not proxy TCP connections (that is it does not send SYN-ACK to the client), it does not completely shut out SYN attacks. By using the SYN packet rate filter, you can control the rate of SYNs to the server. To control the rate of SYNs, set a threshold for the rate of SYNs. To get protection from SYN attacks, you must configure the appliance to proxy TCP connections. However, that requires the reverse traffic to flow through the appliance.
- In a DSR configuration, the NetScaler appliance does not replace the load balancing virtual server's IP address with the destination server's IP address. Instead, it forwards packets to a service by using the server's MAC address. The VIP must be configured on the server and ARP must be disabled for the VIP which is configured on the server to prevent the client request from bypassing the appliance when it is configured in one-arm mode. For example, a user needs to configure VIP in the loopback interface and disable the ARP for the same VIP.
- The appliance obtains the server's MAC address from the monitor bound to the service. However, custom user monitors (monitors of type USER), which use scripts stored on the NetScaler appliance, do not learn a server's MAC address. If you use only custom monitors in a DSR configuration, for each request the virtual server receives, the appliance attempts to resolve the destination IP address to a MAC address (by sending ARP requests). Because the destination IP address is a virtual IP address owned by the NetScaler appliance, the ARP requests always resolve to the MAC address of the NetScaler interface. Consequently, all traffic received by the virtual server is looped back to the appliance. If you use user monitors in a DSR configuration, you must also configure another monitor of a different type (for example, a PING monitor) for the services, ideally with a longer interval between probes, so that the MAC address of the servers can be learned.

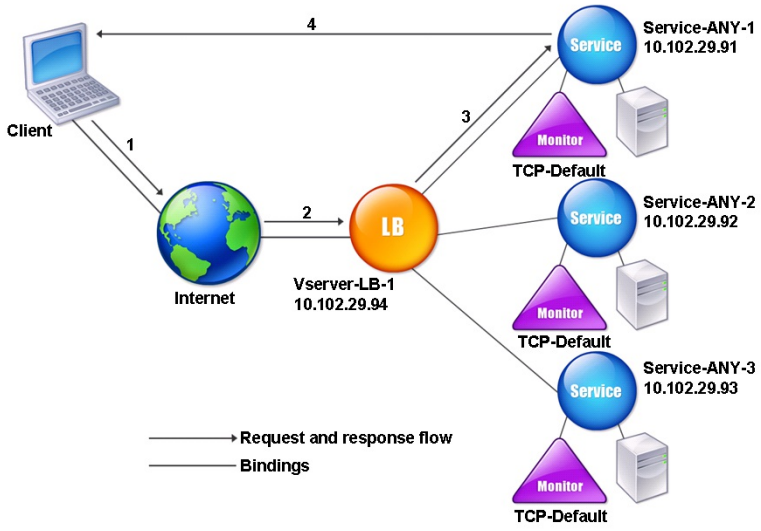
In the example scenario, the services Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to a service, and the service responds to clients directly, bypassing the NetScaler. The following table lists the names and values of the entities configured on the NetScaler in DSR mode.

Entity type	Name	IP address	Protocol
Virtual server	Vserver-LB-1	10.102.29.94	ANY
Services	Service-ANY-1	10.102.29.91	ANY
	Service-ANY-2	10.102.29.92	ANY

Entity type	Name Service-ANY-3	IP address 10.102.29.93	Protocol ANY
Monitors	TCP	None	None

The following diagram shows the load balancing entities and values of the parameters to be configured on the appliance.

Figure 1. Entity Model for Load Balancing in DSR Model



For the appliance to function correctly in DSR mode, the destination IP in the client request must be unchanged. Instead, the appliance changes the destination MAC to that of the selected server. This setting enables the server to determine the client MAC address for forwarding requests to the client while bypassing the server.

Next, you configure a basic load balancing setup as described in Setting Up Basic Load Balancing, naming the entities and setting the parameters using the values described in the previous table.

After you configure the basic load balancing setup, you must customize it for DSR mode. To do this, you configure a supported load balancing method, such as the Source IP Hash method with a sessionless virtual server. You also need to set the redirection mode to allow the server to determine the client MAC address for forwarding responses and bypass the appliance.

After you configure the load balancing method and redirection mode, you need to enable the USIP mode on each service. The service then uses the source IP address when forwarding responses.

To configure the load balancing method and redirection mode for a sessionless virtual server by using the command line interface

At the command prompt, type:

set lb vserver <vServerName> -lbMethod <LBMethodOption> -m <RedirectionMode> -sessionless <Value>

Example

```
set lb vserver Vserver-LB-1 -lbMethod SourceIPHash -m MAC -sessionless enabled
```

> **Note**
>
> For a service that is bound to a virtual server on which -m MAC option is enabled, you must bind a non-user monitor.

To configure the load balancing method and redirection mode for a sessionless virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open a virtual server, select Redirection Mode as MAC Based, and method as SOURCEIPHASH.
3. In Traffic Settings, select Sessionless Load Balancing.

To configure a service to use source IP address by using the command line interface

At the command prompt, type:

set service <ServiceName> -usip <Value>

Example

```
set service Service-ANY-1 -usip yes
```

To configure a service to use source IP address by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open a service, and in Traffic Settings, select Use Source IP Address.

Some additional steps are required in certain situations, which are described in the succeeding sections.

Use Case 4: Configuring LINUX Servers in DSR Mode

Jun 08, 2015

The LINUX operating system requires that you set up a loopback interface with the NetScaler appliance virtual IP address (VIP) on each load balanced server in the DSR cluster.

To configure LINUX server in DSR mode

To create a loop back interface with the NetScaler appliance's VIP on each load balanced server, at the Linux OS prompt type the following commands:

ifconfig dummy0 up

ifconfig dummy0:0 inet <netscaler vip> netmask 255.255.255.255 up

echo 1 > /proc/sys/net/ipv4/conf/dummy0/arp_ignore

echo 2 > /proc/sys/net/ipv4/conf/dummy0/arp_announce

Then, run the software that re-maps the TOS id to VIP.

Note: Add the correct mappings to the software before running it. In the preceding commands, the LINUX server uses dummy0 to connect to the network. When you use this command, type the name of the interface that your LINUX server uses to connect to the network.

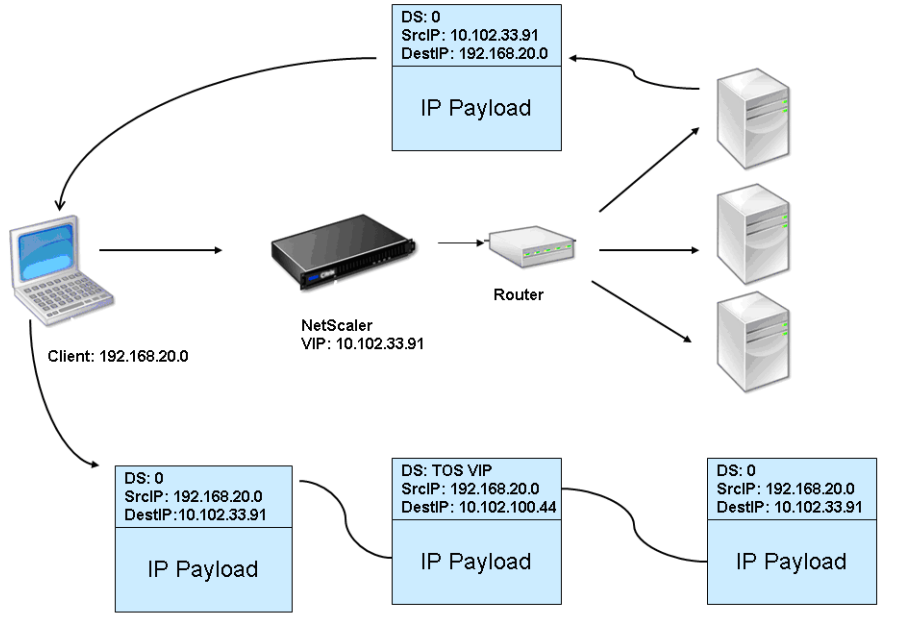
Use Case 5: Configuring DSR Mode When Using TOS

Feb 13, 2017

Differentiated services (DS), also known as TOS (Type of Service), is a field that is part of the TCP packet header. TOS is used by upper layer protocols for optimizing the path for a packet. The TOS information encodes the NetScaler appliance virtual IP address (VIP), and the load balanced servers extract the VIP from it.

In the following scenario, the appliance adds the VIP to the TOS field in the packet and then forwards the packet to the load balanced server. The load balanced server then responds directly to the client, bypassing the appliance, as illustrated in the following diagram.

Figure 1. The NetScaler Appliance in DSR mode with TOS



The TOS feature is specifically customized for a controlled environment, as described below:

- The environment must not have any stateful devices, such as stateful firewall and TCP gateways, in the path between the appliance and the load balanced servers.
- Routers at all the entry points to the network must remove the TOS field from all incoming packets to make sure that the load balanced server does not confuse another TOS field with that added by the appliance.
- Each server can have only 63 VIPs.
- The intermediate router must not send out ICMP error messages regarding fragmentation. The client will not understand the message, as the source IP address will be the IP address of the load balanced server and not the NetScaler VIP.
- TOS is valid only for IP-based services. You cannot use domain name based services with TOS.

In the example, Service-ANY-1 is created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to the service, and the service responds to clients directly, bypassing the appliance. The following table lists the names and values of the entities configured on the appliance in DSR mode.

Entity Type	Name	IP Address	Protocol

Entity Type	Name	IP Address	Protocol
Virtual server	Vserver-LB-1	10.102.33.91	ANY
Services	Service-ANY-1	10.102.100.44	ANY
Monitors	PING	None	None

DSR with TOS requires that load balancing be set up on layer 3. To configure a basic load balancing setup for Layer 3, see Setting Up Basic Load Balancing. Name the entities and set the parameters using the values described in the previous table.

After you configure the load balancing setup, you must customize the load balancing setup for DSR mode by configuring the redirection mode to allow the server to decapsulate the data packet and then respond directly to the client and bypass the appliance.

After specifying the redirection mode, you can optionally enable the appliance to transparently monitor the server. This enables the appliance to transparently monitor the load balanced servers.

To configure the redirection mode for the virtual server by using the command line interface

At the command prompt, type:

set lb vserver <vServerName> -m <Value> -tosId <Value>

Example

set lb vserver Vserver-LB-1 -m TOS -tosId 3

To configure the redirection mode for the virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open a virtual server, and in Redirect Mode, select TOS ID.

To configure the transparent monitor for TOS by using the command line interface

At the command prompt, type:

add monitor <MonitorName> <Type> -destip <DestinationIP> -tos <Value> -tosId <Value>

Example

add monitor mon1 PING -destip 10.102.33.91 -tos Yes -tosId 3

To create the transparent monitor for TOS by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Create a monitor, select TOS, and type the TOS ID that you specified for the virtual server.

Wildcard TOS Monitors

In a load balancing configuration in DSR mode using TOS field, monitoring its services requires a TOS monitor to be created and bound to these services. A separate TOS monitor is required for each load balancing configuration in DSR mode using TOS field, because a TOS monitor requires the VIP address and the TOS ID to create an encoded value of the VIP address. The monitor creates probe packets in which the TOS field is set to the encoded value of the VIP address. It then sends the

probe packets to the servers represented by the services of a load balancing configuration.

With a large number of load balancing configurations, creating a separate custom TOS monitor for each configuration is a big, cumbersome task. Managing these TOS monitors is also a big task. Now, you can create wildcard TOS monitors. You need to create only one wildcard TOS monitor for all load balancing configurations that use the same protocol (for example, TCP or UDP).

A wildcard TOS monitor has the following mandatory settings:

- Type = <protocol>
- TOS = Yes

The following parameters can be set to a value or can be left blank:

- Destination IP
- Destination Port
- TOS ID

A wildcard TOS monitor (with destination IP, Destination port, and TOS ID not set) bound to a DSR service automatically learns the TOS ID and the VIP address of the load balancing virtual server. The monitor creates probe packets with TOS field set to the encoded VIP address and then sends the probe packets to the server represented by the DSR service.

To create a wildcard TOS monitor by using the NetScaler command line

At the command prompt, type:

- **add lb monitor** <monitorName> <Type> -**tos** YES
- **show lb monitor** <monitorName>

To bind a wildcard TOS monitor to a service by using the NetScaler command line

At the command prompt, type:

- **bind lb monitor** <monitorName> <serviceName>
- **show lb monitor** <monitorName>

To create a wildcard TOS monitor by using the NetScaler GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Monitors**.
2. Add a monitor with the following parameter settings:
   - Type = <protocol>
   - TOS = YES

To bind a wildcard TOS monitor to a service by using the NetScaler GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**.
2. Open a service and bind a wildcard TOS monitor to it.

In the following sample configuration, V1, V2, and V3 are load balancing virtual servers of type ANY and has TOS ID set to 1, 2, and 3 respectively. S1, S2,S3, S4, and S5 are services of type ANY. S1 and S2 are bound to both V1 and V2. S3, S4 and S5 and bound to both V1 and V3. WLCD-TOS-MON is a wildcard TOS monitor with type TCP and is bound to S1, S2, S3, S4 and S5.

WLCD-TOS-MON automatically learns the TOD ID and VIP address of virtual servers bound to S1, S2, S3, S4, and S5.

Because S1 is bound to V1 and V2, WLCD-TOS-MON creates two types of probe packets for S1, one with TOS field set to the encoded VIP address (203.0.113.1) of V1 and and the other with the VIP address (203.0.113.2) of V2. The NetScaler then sends these probe packets to the server represented by S1. Similarly, WLCD-TOS-MON creates probe packets for S2, S3, S4, and S5.

Sample Configuration COPY

```
> add lb monitor WLCD-TOS-MON  TCP -tos YES

Done

> add lb vserver V1 ANY 203.0.113.1 * -m TOS –tosID 1

Done

> add lb vserver V2 ANY 203.0.113.2 * -m TOS –tosID 2

Done

> add lb vserver V3 ANY 203.0.113.3 * -m TOS –tosID 3

Done

> add service S1 198.51.100.1 ANY *

Done

> add service S2 198.51.100.2 ANY *

Done

> add service S3 198.51.100.3 ANY *

Done

> add service S4 198.51.100.4 ANY *

Done

> add service S5 198.51.100.5 ANY *

Done

> bind lb monitor WLCD-TOS-MON S1
```

```
> bind lb monitor WLCD-TOS-MON S1

Done

> bind lb monitor WLCD-TOS-MON S2

Done

> bind lb monitor WLCD-TOS-MON S3

Done

> bind lb monitor WLCD-TOS-MON S4

Done

> bind lb monitor WLCD-TOS-MON S5

Done

> bind lb vserver V1 S1, S2, S3, S4, S5

Done

> bind lb vserver V2, S1, S2

Done

> bind lb vserver V3 S3, S4, S5

Done
```

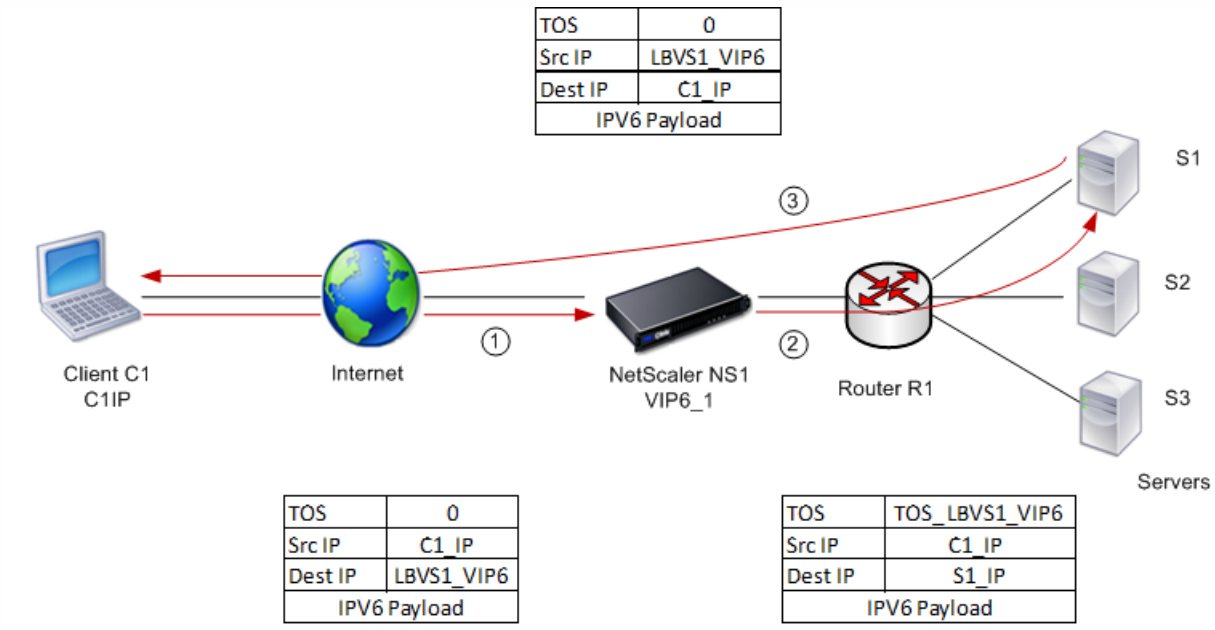
Use Case 6: Configuring Load Balancing in DSR Mode for IPv6 Networks by Using the TOS Field

Jun 08, 2015

You can configure load balancing in Direct Server Return (DSR) mode for IPv6 networks by using the Type of Service (TOS) field when the NetScaler appliance and the servers are in different networks.

Note: The TOS field is also called the Traffic Class field.
In DSR mode, when a client sends a request to a VIP6 address on a NetScaler appliance, the appliance forwards this request to the server by changing the destination IPv6 address of the packet to the IPv6 address of the server and sets an encoded value of the VIP6 address in the TOS (also called traffic class) field of the IPv6 header. You can configure the server to use the information in the TOS field to derive the VIP6 address from the encoded value, which is then used as source IP address in response packets. Response traffic directly goes to the client, bypassing the NetScaler.

Consider an example where a load balancing virtual server LBVS1, configured on a NetScaler appliance NS1, is used to load balance traffic across servers S1, S2, and S3. The NetScaler appliance NS1 and the servers S1, S2, and S3 are in different networks so router R1 is deployed between NS1 and the servers.



The following table lists the settings used in this example.

Entities	Name
IPv6 address of client C1	C1_IP (for reference purposes only)
Load balancing virtual server on NS1	LBVS1
IPv6 address of LBVS1	LBVS1_VIP6 (for references purpose only)
TOS value	TOS_ LBVS1_VIP6 (for references purpose only)

Entities	Name
Service for server S1 on NS1	SVC_S1
IPv6 address for server S1	S1_IP (for references purpose only)
Service for server S2 on NS1	SVC_S2
IPv6 address for server S1	S2_IP (for references purpose only)
Service for server S3 on NS1	SVC_S3
IPv6 address for server S1	S3_IP (for references purpose only)

Following is the traffic flow in the example scenario:

1. Client C1 sends a request to virtual server LBVS1.
2. LBVS1's load balancing algorithm selects server S1 and the appliance opens a connection to S1. NS1 sends the request to S1 with:
   - TOS field set to TOS_ LBVS1_VIP6.
   - Source IP address as C1_IP.
3. The server S1, on receiving the request, uses the information in the TOS field to derive the LBVS1_VIP6 address, which is the IP address of the virtual server LBVS1 on NS1. The server directly sends the response to C1, bypassing the NetScaler, with:
   - Source IP address set to the derivedLBVS1_VIP6 address so that the client communicates to the virtual server LBVS1 on NS1 and not to server S1.

To configure load balancing in DSR Mode using TOS, perform the following steps on the appliance:

1. Enable USIP mode globally.
2. Add the servers as services.
3. Configure a load balancing virtual server with a TOS value.
4. Bind the services to the virtual server.

To configure load balancing in DSR Mode using TOS by using the command line interface

At the command prompt, type:

- enable ns mode USIP
- add service <serviceName> <IP> <serviceType> <port>
  Repeat the above command as many times as necessary to add each server as a service on the NetScaler appliance.
- add lb vserver <name> <serviceType> <ip> <port> -m <redirectionMode> -tosId <positive_integer>
- bind lb vserver <vserverName> <serviceName>

To enable USIP mode by using the configuration utility

Navigate to System > Settings > Configure Modes, and select Use Source IP Address.

To create services by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, and create a service.

To create a load balancing virtual server and bind services by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and create a virtual server.

2. Click in the Service section to bind a service to this virtual server.

Use Case 7: Configuring Load Balancing in DSR Mode by Using IP Over IP

Jul 18, 2017

You can configure your NetScaler appliance to use direct server return (DSR) mode across Layer 3 networks by using IP tunneling, also called *IP over IP* configuration. As with standard load balancing configurations for DSR mode, this allows servers to respond to clients directly instead of using a return path through the NetScaler appliance, improving response times and throughput. As with standard DSR mode, the NetScaler appliance monitors the servers and performs health checks on the application ports.

With IP over IP configuration, the NetScaler appliance and the servers do not need to be on the same Layer 2 subnet. Instead, the NetScaler appliance encapsulates the packets before sending them to the destination server. After the destination server receives the packets, it decapsulates the packets, and then sends its responses directly to the client.

To configure IP over IP DSR mode on your NetScaler appliance, you must do the following:

- **Create a load balancing virtual server.** Set the protocol to ANY and set the mode to IPTUNNEL.
- **Create services.** Create a service for each of your back-end applications. Bind the services that you created to the virtual server.
- **Configure for decapsulation:** You can configure either a NetScaler appliance or a backend server to act as a decapsulator.

Configuring a Load Balancing Virtual Server

Updated: 2013-11-29

Configure a virtual server to handle requests to your applications. Assign a service type of ANY and set the forwarding method to IPTUNNEL. Optionally, configure the virtual server to operate in sessionless mode. You can configure any load balancing method that you want to use.

To create and configure a load balancing virtual server for IP over IP DSR by using the command line interface

At the command prompt type the following command to configure a load balancing virtual server for IP over IP DSR and verify the configuration:

- add lb vserver <name> serviceType <serviceType> IPAddress <ip> Port <port> -lbMethod <method> -m <ipTunnelTag> -sessionless <sessionless>
- show lb vserver <name>

Example

In the following example, we have selected the load balancing method as sourceIPhash and configured sessionless load balancing.

```
add lb vserver Vserver-LB-1 ANY 10.102.29.60 * -lbMethod SourceIPHash -m IPTUNNEL -sessionless enabled
```

To create and configure a load balancing virtual server for IP over IP DSR by using

the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Create a virtual server, and specify Redirection Mode as IP Tunnel Based.

Configuring Services for IP over IP DSR

Updated: 2013-11-29

After creating your load-balanced server, You must configure one service for each of your applications. The service handles traffic from the NetScaler appliance to those applications, and allows the NetScaler appliance to monitor the health of each application.

You assign a service type of ANY and configure it for USIP mode. Optionally, you can also bind a monitor of type IPTUNNEL to the service for tunnel-based monitoring.

To create and configure a service for IP over IP DSR by using the command line interface

At the command prompt, type the following commands to create a service and optionally, create a monitor and bind it to the service:

- add service <serviceName> <serverName> <serviceType> <port> -usip <usip>
- add monitor <monitorName> <monitorType> -destip <ip> -iptunnel <iptunnel>
- bind service <serviceName> -monitorName <monitorName>

Example

In the following example, we are creating a monitor of type IPTUNNEL:

```
add monitor mon-1 PING -destip 10.102.29.60 -iptunnel yes
add service Service-DSR-1 10.102.30.5 ANY * -usip yes
bind service Service-DSR-1 -monitorName mon-1
```

To configure a monitor by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Monitors.
2. Create a monitor, and select IP Tunnel.

To create and configure a service for IP over IP DSR by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Create a service and, in Settings, select Use Source IP Address.

To bind a service to a load balancing virtual server by using the command line interface

At the command prompt type the following command:

bind lb vserver <name> <serviceName>

Example

bind lb vserver Vserver-LB-1 Service-DSR-1

To bind a service to a load balancing virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open a virtual server, and click in the Services section to bind a service to the virtual server.

Decapsulator configuration

- When a NetScaler appliance is used as a decapsulator, an IP tunnel must be created in the NetScaler appliance. For details, see Configuring IP Tunnels.

Example configuration:

NetScaler as encapsulator COPY

```
add lb vserver v1 any 1.1.1.1 * -m IPTUNNEL

add service s1 2.2.2.2 ANY *

bind lb vserver v1 s1
```

NetScaler as decapsulator COPY

```
add iptunnel tun1 <snip_in_encap> netmask *

add ns ip 1.1.1.1 255.255.255.255 –type vip –arp disabled

add lb vserver v1 any 1.1.1.1 *

add service s1 <actualserverip> ANY *

bind lb vserver v1 s1
```

- When a backend server is used as a decapsulator, the backend configuration varies depending on the server type. The steps involved in configuring a backend server as a decapsulator are;

1. Configure a loop back interface.
2. Add a route through tunnel interface.

Note: Make sure that the tunnel modules are installed in the system.

Example configuration:

In this example, 1.1.1.1 is the NetScaler virtual IP (VIP) address and 2.2.2.2 is the backend server IP address.

The VIP address is configured in the loopback interface and a route is added through the tunnel interface. The modprobe ipip command is used for enabling the tunnel interface.

NetScaler as encapsulator COPY

```
add lb vserver v1 ANY 1.1.1.1 80 -m IPTUNNEL

add service svc1 2.2.2.2 ANY 80 -usip YES -useproxyport NO

bind lb vserver v1 svc1
```

Backend server as decapsulator

COPY

```
ifconfig lo inet 1.1.1.1 netmask 255.255.255.255

modprobe ipip

echo 1 > /proc/sys/net/ipv4/conf/tunl0/arp_ignore

echo 2 > /proc/sys/net/ipv4/conf/tunl0/arp_announce

ifconfig tunl0 1.1.1.1 netmask 255.255.255.255 up

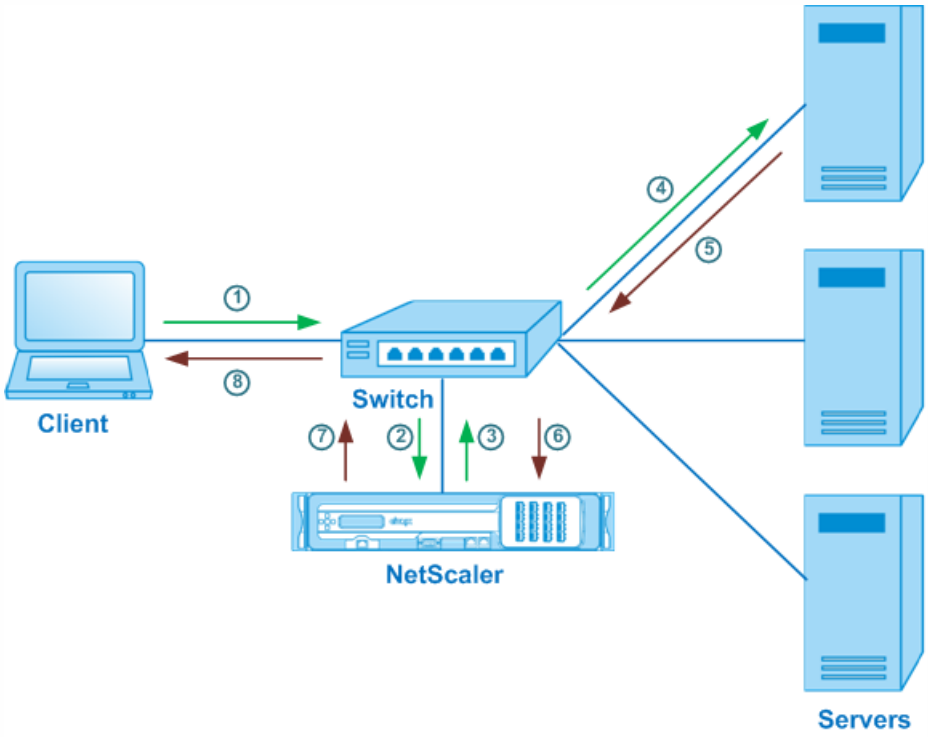
route add -host 1.1.1.1 dev tunl0
```

Use Case 8: Configuring Load Balancing in One-arm Mode

Feb 25, 2016

In a one-arm setup, you connect the NetScaler appliance to the network through a single VLAN. The appliance receives the request from the client on a single VLAN and it sends the request to the server on the same VLAN. This is one of the simplest deployment scenarios, where the router, the servers and the appliance are all connected to the same switch. Client requests at the switch are forwarded to the appliance, and the appliance uses the configured load balancing method to select the service, as is shown in the following diagram.

Figure 1. Load Balancing in One-Arm Mode



In the example scenario, the services Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to the virtual server Vserver-LB-1. The virtual server load balances the client request to a service. The following table lists the names and values of the entities configured on the appliance in one-arm mode.

Entity type	Name	IP address	Protocol
Virtual server	Vserver-LB-1	10.102.29.94	ANY
Services	Service-ANY-1	10.102.29.91	ANY
	Service-ANY-2	10.102.29.92	ANY

Entity type	Name	IP address	Protocol
Monitors	TCP	None	None
Service-ANY-3		10.102.29.93	ANY

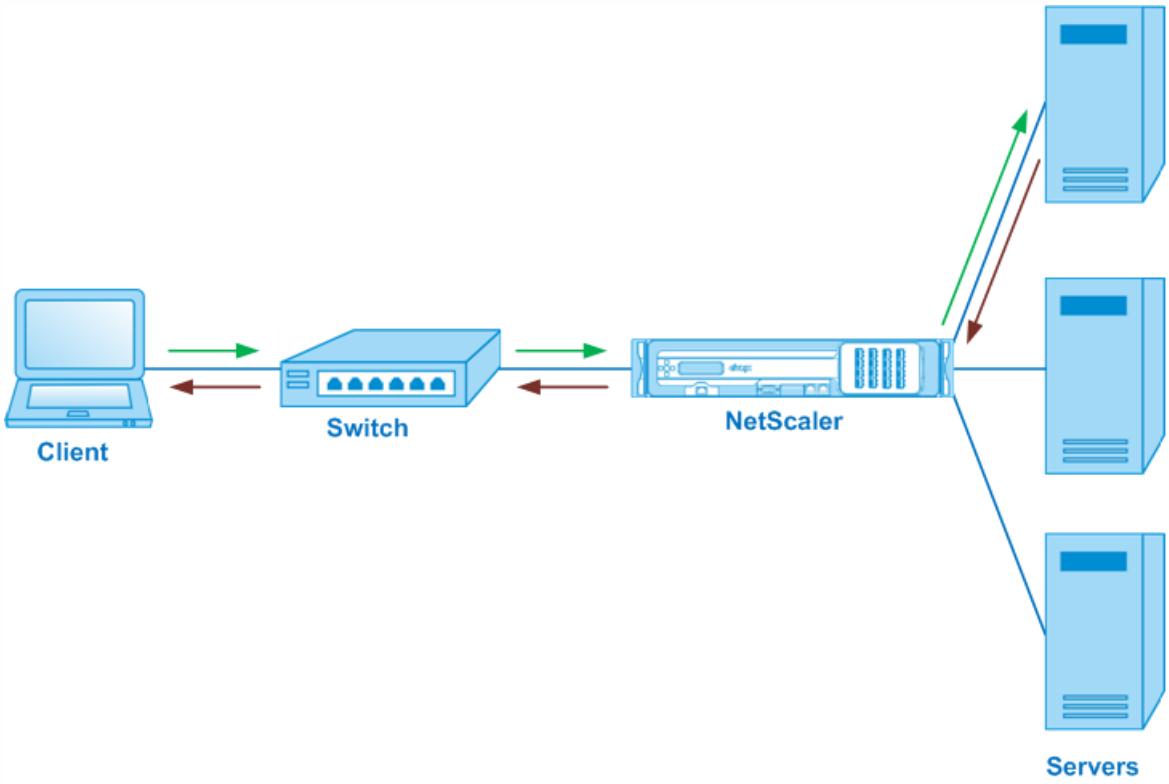
To configure a load balancing setup in one-arm mode, see "Setting Up Basic Load Balancing."

Use Case 9: Configuring Load Balancing in the Inline Mode

Feb 19, 2016

In an inline mode (also called two-arm mode) setup, you connect the NetScaler appliance to the network through multiple VLANs. The appliance receives the request from the client on one VLAN and it sends the request to the server on another VLAN. In the two-arm setup, the appliance is connected between the servers and the client. Client requests at the switch are forwarded to the appliance, and the appliance uses the configured load balancing method to select the service. This is shown in the following diagram.

Figure 1. Load Balancing in Inline Mode



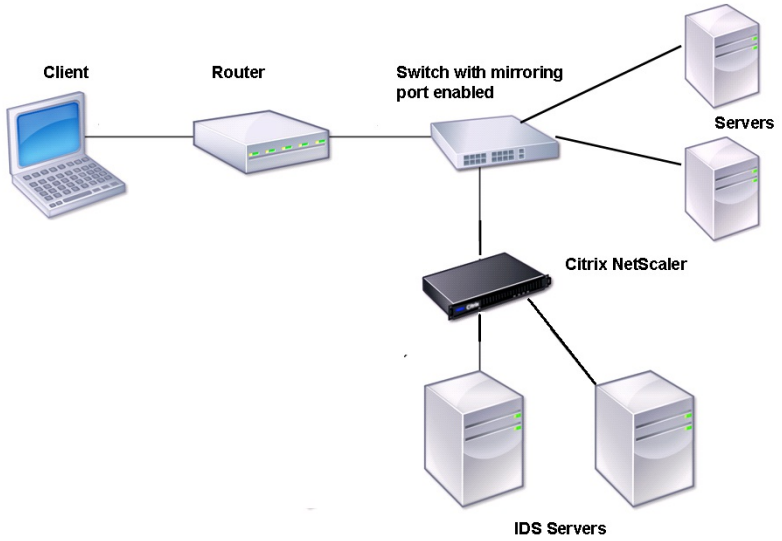
The configuration and the entity diagram for inline mode are the same as described in "Configuring Load Balancing in One-arm Mode."

Use Case 10: Load Balancing of Intrusion Detection System Servers

Feb 13, 2017

To enable the NetScaler appliance to support load balancing of intrusion detection system (IDS) servers, the IDS servers and clients must be connected through a switch that has port mirroring enabled. The client sends a request to the server. Because port mirroring is enabled on the switch, the request packets are copied or sent to the NetScaler appliance virtual server port. The appliance then uses the configured load balancing method to select an IDS server, as shown in the following diagram.

Figure 1. Topology of Load Balanced IDS Servers



Note: Currently, the appliance supports load balancing of passive IDS devices only.
As illustrated in the preceding diagram, the IDS load balancing setup functions as follows:

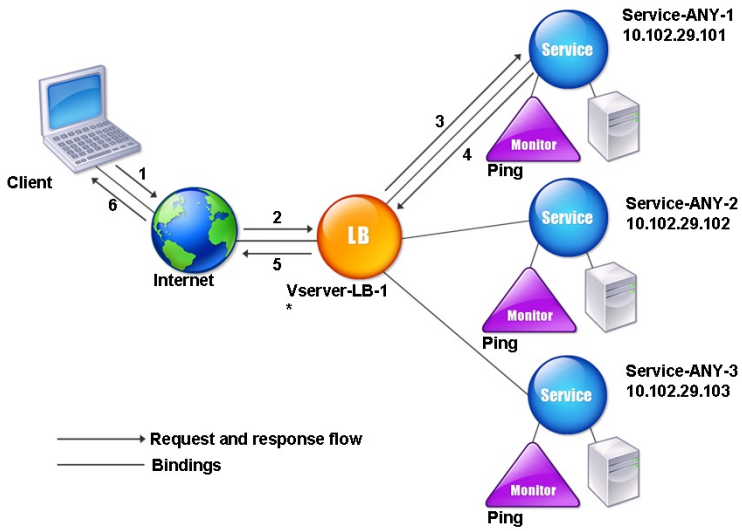
1. The client request is sent to the IDS server, and a switch with a mirroring port enabled forwards these packets to the IDS server. The source IP address is the IP address of the client, and the destination IP address is the IP address of the server. The source MAC address is the MAC address of the router, and the destination MAC address is the MAC address of the server.
2. The traffic that flows through the switch is mirrored to the appliance. The appliance uses the layer 3 information (source IP address and destination IP address) to forward the packet to the selected IDS server without changing the source IP address or destination IP address. It modifies the source MAC address and the destination MAC address to the MAC address of the selected IDS server.

Note: When load balancing IDS servers, you can configure the SRCIPHASH, DESTIPHASH, or SRCIPDESTIPHASH load balancing methods. The SRCIPDESTIPHASH method is recommended because packets flowing from the client to a service on the appliance must be sent to a single IDS server.
Suppose Service-ANY-1, Service-ANY-2, and Service-ANY-3 are created and bound to Vserver-LB-1. The virtual server balances the load on the services. The following table lists the names and values of the entities configured on the appliance.

Entity type	Name	IP address	Port	Protocol
Virtual server	Vserver-LB-1	*	*	ANY
Services	Service-ANY-1	10.102.29.101	*	ANY
	Service-ANY-2	10.102.29.102	*	ANY
	Service-ANY-3	10.102.29.103	*	ANY
Monitors	Ping	None	None	None

Note: You can use inline mode or one-arm mode for an IDS load balancing setup.
The following diagram shows the load balancing entities and values of the parameters to be configured on the appliance.

Figure 2. Entity Model for Load Balancing IDS Servers



To configure an IDS load balancing setup, you must first enable MAC-based forwarding. You must also disable layer 2 and layer 3 modes on the appliance.

To enable MAC-based forwarding by using the command line interface

At the command prompt, type:

enable ns mode <ConfigureMode>

Example

enable ns mode MAC

To enable MAC-based forwarding by using the configuration utility

Navigate to System > Settings > Configure Modes, and select MAC Based Forwarding.

Next, see "Setting Up Basic Load Balancing", to configure a basic load balancing setup.

After you configure the basic load balancing setup, you must customize it for IDS by configuring a supported load balancing method (such as the SRCIPDESTIP Hash method on a sessionless virtual server) and enabling MAC mode. The appliance does not maintain the state of the connection and only forwards the packets to the IDS servers without processing them. The destination IP address and port remains unchanged because the virtual server is in the MAC mode.

To configure LB method and redirection mode for a sessionless virtual server by using the command line interface

At the command prompt, type:

set lb vserver <vServerName> -lbMethod <LBMethodOption> -m <RedirectionMode> -sessionless <Value>

Example

set lb vserver Vserver-LB-1 -lbMethod SourceIPDestIPHash -m MAC -sessionless enabled

> **Note**
>
> For a service that is bound to a virtual server on which -m MAC option is enabled, you must bind a non-user monitor.

To configure LB method and redirection mode for a sessionless virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open a virtual server and, in Redirection Mode, select MAC Based.
3. In Advanced Settings, click Methods, and select SRCIPDESTIPHASH. Click Traffic Settings, and select Sessionless Load Balancing.

To set a service to use source IP address by using the command line interface

At the command prompt, type:

set service <ServiceName> -usip <Value>

Example

set service Service-ANY-1 -usip yes

To set a service to use source IP address by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. Open a service, and in Settings select Use Source IP Address.

For USIP to function correctly, you must set it globally. For more information about configuring USIP globally, see "IP Addressing."

Use Case 11: Isolating Network Traffic using Listen Policies

Feb 13, 2017

A very common security requirement in a data center is to maintain network path isolation between the traffic of various applications or tenants. One application or tenant's traffic must be isolated from the traffic of other applications or tenants. For example, a financial services company would want to keep the traffic of its insurance department's applications separate from that of its financial services applications. In the past, this was easily achieved through physical separation of network service devices such as firewalls, load balancers, and IDP, and network monitoring and logical separation in the switching fabric.

As data center architectures evolve toward multi-tenant virtualized data centers, networking services in the aggregation layer of a data center are getting consolidated. This development has made network path isolation a critical component for network service devices and is driving the requirement for ADCs to be able to isolate traffic at the L4 to L7 levels. Furthermore, all the traffic of a particular tenant must go through a firewall before reaching the service layer.

To address the requirement of isolating the network paths, a NetScaler appliance identifies network domains and controls the traffic across the domains. The NetScaler solution has two main components: listen policies and shadow virtual servers.

Each network path to be isolated is assigned a virtual server on which a listen policy is defined so that the virtual server listens to traffic only from a specified network domain.

To isolate the traffic, listen policies can be based on a number of client parameters or their combinations, and the policies can be assigned priorities. The following table lists the parameters that can be used in listen policies for identifying the traffic.

Table 1. Client Parameters Used to Define Listen Policies

Category	Parameters
Ethernet protocol	Source MAC address, destination MAC address
Network interface	Network ID, receiving throughput, sending throughput, transmission throughput
IP protocol	Source IP address, destination IP address
IPv6 protocol	Source IPv6 address, destination IPv6 address
TCP protocol	Source port, destination port, maximum segment size, payload, and other options
UDP protocol	Source port, destination port
VLAN	ID

On the NetScaler appliance, a virtual server is configured for each domain, with a listen policy specifying that the virtual server is to listen only to traffic for that domain. Also configured for each domain is a shadow load balancing virtual server, which listens to traffic destined for any domain. Each of the shadow load balancing virtual servers has a wildcard (*) IP address and port, and its service type is set to ANY.

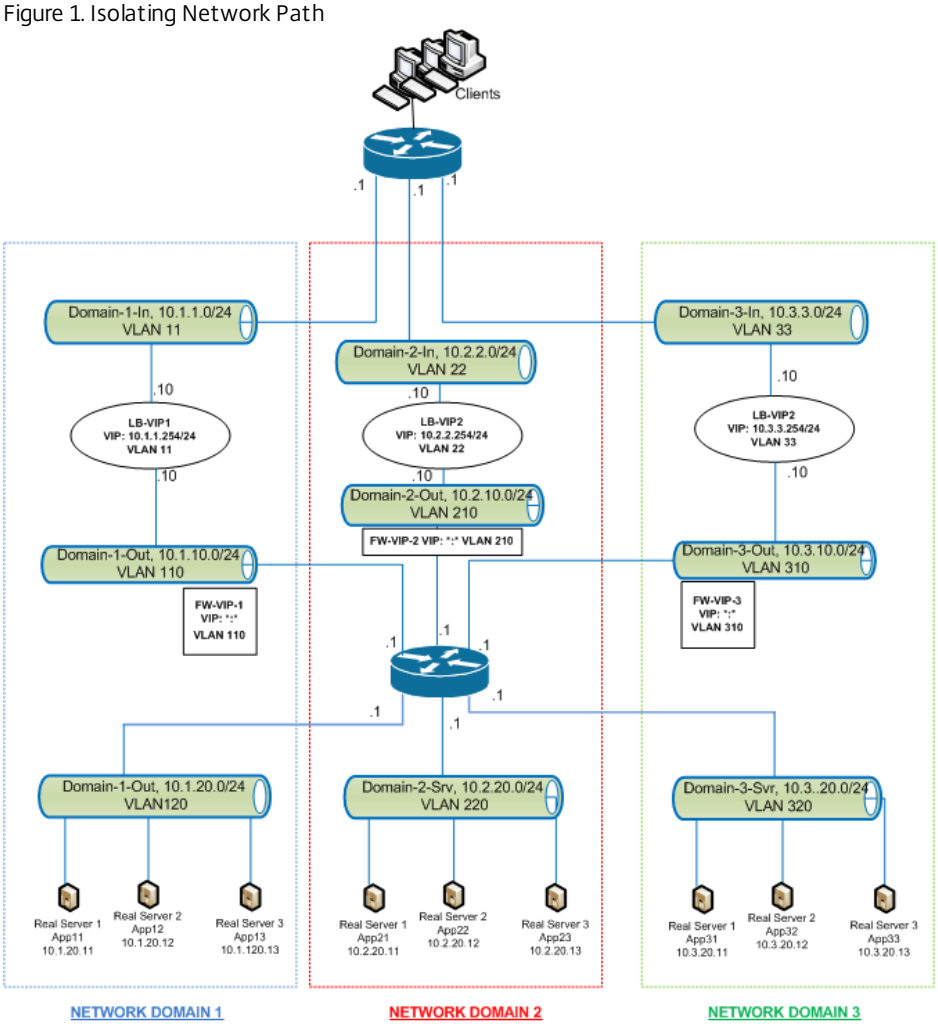
In each domain, a firewall for the domain is bound as a service to the shadow load balancing virtual server, which forwards all traffic through the firewall. Local traffic is forwarded to its destination, and traffic destined for another domain is forwarded to the firewall for that domain. The shadow load balancing virtual servers are configured for MAC mode redirection.

How Network Paths Are Isolated

The following figure shows a typical traffic flow across domains. Consider the traffic flow within Network Domain 1, and between Network

Domain 1 and Network Domain 2.

Figure 1. Isolating Network Path



Traffic within Network Domain 1

Network Domain 1 has three VLANs: VLAN 11, VLAN110, and VLAN120. The following steps describe the traffic flow.

- A client from VLAN 11 sends a request for a service available from the service pool in VLAN 120.
- The load balancing virtual server LB-VIP1, which is configured to listen to traffic from VLAN 11, receives the request and forwards the request to VLAN 110. The virtual server in VLAN 110 forwards the request to shadow load balancing virtual server FW-VIP-1.
- FW-VIP-1, which is configured to listen to traffic from VLAN 110, receives the request and forwards it to VLAN 120.
- The load balancing virtual server in VLAN 120 load balances the request to one of the physical servers, App11, App12, or App13.
- The response sent by the physical server returns by the same path to the client in VLAN 11.

This configuration ensures that traffic is always segregated inside the NetScaler for all the traffic that originates from a client.

Traffic between Network Domain 1 and Network Domain 2

Network Domain 1 has three VLANs: VLAN 11, VLAN 110, and VLAN 120. Network Domain 2 also has three VLANS: VLAN 22, VLAN 210, and VLAN 220. The following steps describe the traffic flow from VALN 11 to VLAN 22.

- A client from VLAN 11, which belongs to Network Domain 1, sends a request for a service available from the service pool in VLAN 220, which belongs to the Network Domain 2.
- In Network Domain 1, the load balancing virtual server LB-VIP1, which is configured to listen to traffic from VLAN 11, receives the request and forwards the request to VLAN 110.
- Shadow load balancing virtual server FW-VIP-1, which is configured to listen to VLAN 110 traffic destined to any other domain, receives the request and forwards it to firewall virtual server FW-VIP-2 because the request is destined to a physical server in Network Domain 2.

- In Network Domain 2, FW-VIP-2 forwards the request to VLAN 220.
- The load balancing virtual server in VLAN 220 load balances the request to one of the physical servers, App21, App22, or App23.
- The response sent by the physical server returns by the same path through the firewall in Network Domain 2 and then to Network Domain 1 to reach the client in VLAN 11.

Configuration Steps

To configure network path isolation by using listen policies, do the following:

- Add listen policy expressions. Each expression specifies a domain to which traffic is destined. You can use the VLAN ID or other parameters to identify the traffic.
- For each network domain, configure two virtual servers as follows:
  - Create a load balancing virtual server for which you specify a listen policy that identifies the traffic destined for this domain. You can specify the name of an expression created earlier, or you can create a new expression while creating the virtual server.
  - Create another load balancing virtual server, referred to as shadow virtual server, for which you specify a listen policy expression that applies to traffic destined for any domain. On this virtual server, set the service type to ANY and the IP address and port to an asterisk (*). Enable MAC-based forwarding on this virtual server.
  - Enable the L2 Connection option on both the virtual servers.
    Generally, to identify a connection, the NetScaler uses the 4-tuple of client IP address, client port, destination IP address, and destination port. When you enable the L2 Connection option, the Layer 2 parameters of the connection (channel number, MAC address, and VLAN ID) are used in addition to the normal 4-tuple.
- Add services representing the server pools in the domain, and bind them to the virtual server.
- Configure the firewall for each domain as a service, and bind all of the firewall services to the shadow virtual server.

To isolate network traffic by using the command line interface

At the command prompt, type the following commands:

- add policy expression <expressionName> <listenPolicyExpression>
- add lb vserver <name> <serviceType> <ip> <port> -l2conn ON -listenPolicy <expressionName>
  Add a load balancing virtual server for each domain. This virtual server is for traffic of the same domain.
- add lb vserver <name> ANY * * -l2conn ON -m MAC -listenPolicy <expressionName>
  Add a shadow load balancing virtual server for each domain. This virtual server is for traffic of other domains.

Example

```
add policy expression e110 client.vlan.id==110
add policy expression e210 client.vlan.id==210
add policy expression e310 client.vlan.id==310
add policy expression e11 client.vlan.id==11
add policy expression e22 client.vlan.id==22
add policy expression e33 client.vlan.id==33

add lb vserver LB-VIP1 HTTP 10.1.1.254 80 -persistenceType NONE -listenPolicy e11
-cltTimeout 180 -l2Conn ON

add lb vserver LB-VIP2 HTTP 10.2.2.254 80 -persistenceType NONE - listenPolicy e22
-cltTimeout 180 -l2Conn ON

add lb vserver LB-VIP3 HTTP 10.3.3.254 80 -persistenceType NONE - listenPolicy e33
-cltTimeout 180 -l2Conn ON

add lb vserver FW-VIP-1 ANY * * -persistenceType NONE -lbMethod ROUNDROBIN - listenPolicy e110 -Listenpriority 1 -m MAC -cltTimeout 120
```

```
add lb vserver FW-VIP-2 ANY * * -persistenceType NONE -lbMethod ROUNDROBIN - listenPolicy e210 -Listenpriority 2 -m MAC -cltTimeout 120

add lb vserver FW-VIP-3 ANY * * -persistenceType NONE -lbMethod ROUNDROBIN - listenPolicy e310 -Listenpriority 3 -m MAC -cltTimeout 120

add service RD-1 10.1.1.1 ANY * -gslb NONE -maxClient 0 -maxReq 0 -cip DISABLED
-usip NO -useproxyport NO -sp ON -cltTimeout 120 -svrTimeout 120 -CKA NO -TCPB NO -CMP NO

add service RD-2 10.2.2.1 ANY * -gslb NONE -maxClient 0 -maxReq 0 -cip DISABLED
-usip NO -useproxyport NO -sp ON -cltTimeout 120 -svrTimeout 120 -CKA NO -TCPB NO -CMP NO

add service RD-3 10.3.3.1 ANY * -gslb NONE -maxClient 0 -maxReq 0 -cip DISABLED
-usip NO -useproxyport NO -sp ON -cltTimeout 120 -svrTimeout 120 -CKA NO -TCPB NO -CMP NO

bind lb vserver FW-VIP-1 RD-1

bind lb vserver FW-VIP-2 RD-2

bind lb vserver FW-VIP-3 RD-3
```

To isolate network traffic by using the configuration utility

1. Add services representing the servers, as described in "Creating a Service."
2. Add each firewall as a service:
   1. Navigate to Traffic Management > Load Balancing > Services
   2. Create a service, specifying protocol as ANY, server as firewall's IP address, and port as 80.
3. Configure a load balancing virtual server.
4. Configure the shadow load balancing virtual server.
5. For each network domain, repeat steps 3 and 4.
6. From the Load Balancing Virtual Servers pane, open the virtual servers that you created and verify the settings.

Use Case 12: Configuring XenDesktop for Load Balancing

Dec 27, 2016

For an improved performance in the delivery of virtual desktop applications, you can integrate the NetScaler appliance with Citrix XenDesktop and use the NetScaler load balancing feature to distribute the load across the Web Interface servers and the Desktop Delivery Controller (DDC) servers.

Generally, you use XenDesktop in situations where applications are not compatible with running on a terminal server or XenApp, or if each virtual desktop has unique requirements. In such cases, you need one desktop host for each user that connects. However, the hosts can be pooled so that you need only one host for each currently connected user.

The core application service deployed for XenDesktop is the Desktop Delivery Controller (DDC). The DDC is installed on a server, and its main function is to register desktop hosts and broker client connections to them.

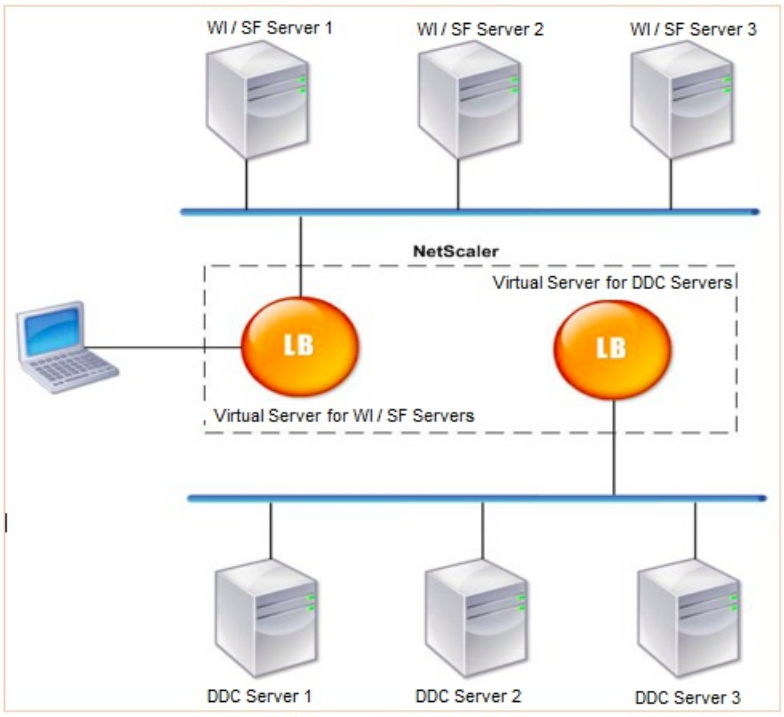
The DDC also authenticates users and manages the assembly of the users' virtual desktop environments by controlling the state of the desktops, and starting and stopping the desktops.

Generally, multiple DDCs are installed to enhance availability.

The Web Interface servers provide secure access to virtual desktops. The Web Interface is the initial connection portal to the Desktop Delivery Controller (DDC). The Web browser on the user's device sends information to the Web server, which communicates with the server farm to provide the user with access to the virtual desktop.

The following figure shows the topology of a NetScaler appliance working with XenDesktop.

Figure 1. **Load Balancing of XenDesktop**



> **Note**
>
> Although you can use the HTTP protocol, Citrix recommends that you use SSL for communication between the client and the NetScaler. You can use the HTTP protocol for communication between the NetScaler and the DDC servers even though you use the SSL protocol for communication with the client.

To configure load balancing for XenDesktop by using the NetScaler GUI

1. Create a service.
   1. Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Services** and click **Add**.
   2. Create a service by specifying a name, an IP address, a port, and a protocol type and then click **OK**.
2. Create a load balancing virtual server.
   1. Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Virtual Servers** and click **Add**.
   2. Create a virtual server by specifying a name, an IP address, a port, and a protocol type and then click **OK**.
3. Bind the service to the load balancing virtual server.
4. Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Virtual Servers** and select a server.
   1. Click **Edit**.
   2. In the **Services and Service Groups**, click **>** and click **Add Binding**.
   3. Select the service you want to bind and enter the weight value.
   4. Click **Bind**.

To configure load balancing for XenDesktop by using the command line interface

- To create a service, at the command prompt, type:

  add service <name> <serverName> <serviceType> <port>

  Example

  add service Service-HTTP-1 192.0.2.5 HTTP 80

- To create a virtual server, at the command prompt, type:

  add lb vserver <name> <serviceType> <ip> <port>

  Example

  add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80

- To bind a service to a load balancing virtual server, at the command prompt, type:

  bind lb vserver <name> <serviceName>

  Example

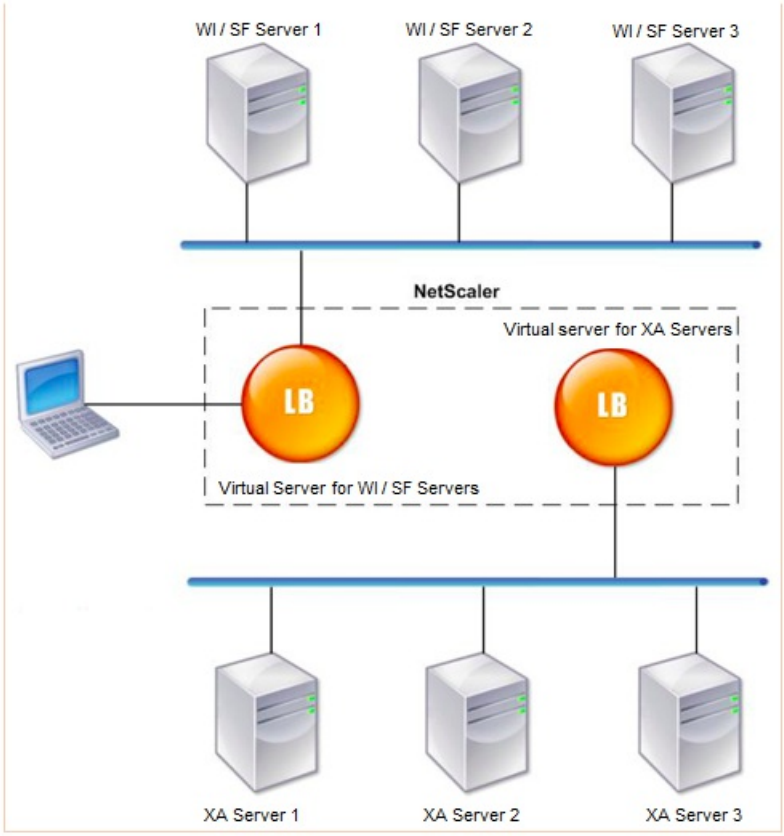
  bind lb vserver Vserver-LB-1 Service-HTTP-1

Use Case 13: Configuring XenApp for Load Balancing

Dec 27, 2016

For efficient delivery of applications, you can integrate the NetScaler appliance with Citrix XenApp and use the NetScaler load balancing feature to distribute the load across the XenApp server farms. The following figure is a topology diagram of such a setup.

Figure 1. **Load Balancing of XenApp**



The Web Interface servers provide secure access to XenApp application resources through the user's Web browser. The Web Interface client presents to the users all the resources, such as applications, content, and desktops that are made available in the XenApp server farms. Users can access the published resources through a standard Web browser or through the Citrix online plug-in.

The Web browser on the user's device sends information to the Web server, which communicates with the servers on the server farm to provide the user with access to the resources.

The Web Interface and the XML Broker are complementary services. The Web Interface provides users with access to applications, and the XML Broker evaluates the user's permissions to determine which applications appear in the Web Interface.

The XML service is installed on all the servers in the server farm. The XML service specified in the Web Interface functions as an XML broker. On the basis of the user credentials passed by the Web Interface server, the XML Broker server sends a list of applications accessible to the user.

In large enterprises where multiple Web Interface servers and XML Broker servers are deployed, Citrix recommends load balancing these servers by using NetScaler. Configure one virtual server to load balance all of the Web Interface servers and another for all of the XML Broker servers. The load balancing method and other features can be configured on the virtual server as required.

> **Note**
>
> Although you can use the HTTP protocol, Citrix recommends that you use SSL for communication between the client and the NetScaler. You can use the HTTP protocol for communication between the NetScaler and the WI servers even though you use the SSL protocol for communication with the client.

To configure load balancing for XenApp by using the NetScaler GUI

1. Create a service.
   1. Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Services** and click **Add**.
   2. Create a service by specifying a name, an IP address, a port, and a protocol type and then click **OK**.
2. Create a load balancing virtual server.
   1. Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Virtual Servers** and click **Add**.
   2. Create a virtual server by specifying a name, an IP address, a port, and a protocol type and then click **OK**.
3. Bind the service to the load balancing virtual server.
4. Navigate to **Configuration** > **Traffic Management** > **Load Balancing** > **Virtual Servers** and select a server.
   1. Click **Edit**.
   2. In the **Services and Service Groups**, click **>** and click **Add Binding**.
   3. Select the service you want to bind and enter the weight value.
   4. Click **Bind**.

To configure load balancing for XenApp by using the command line interface

- To create a service, at the command prompt, type:

  add service <name> <serverName> <serviceType> <port>

  Example

  add service Service-HTTP-1 192.0.2.5 HTTP 80

- To create a virtual server, at the command prompt, type:

  add lb vserver <name> <serviceType> <ip> <port>

  Example

  add lb vserver Vserver-LB-1 HTTP 10.102.29.60 80

- To bind a service to a load balancing virtual server, at the command prompt, type:

  bind lb vserver <name> <serviceName>

  Example

bind lb vserver Vserver-LB-1 Service-HTTP-1

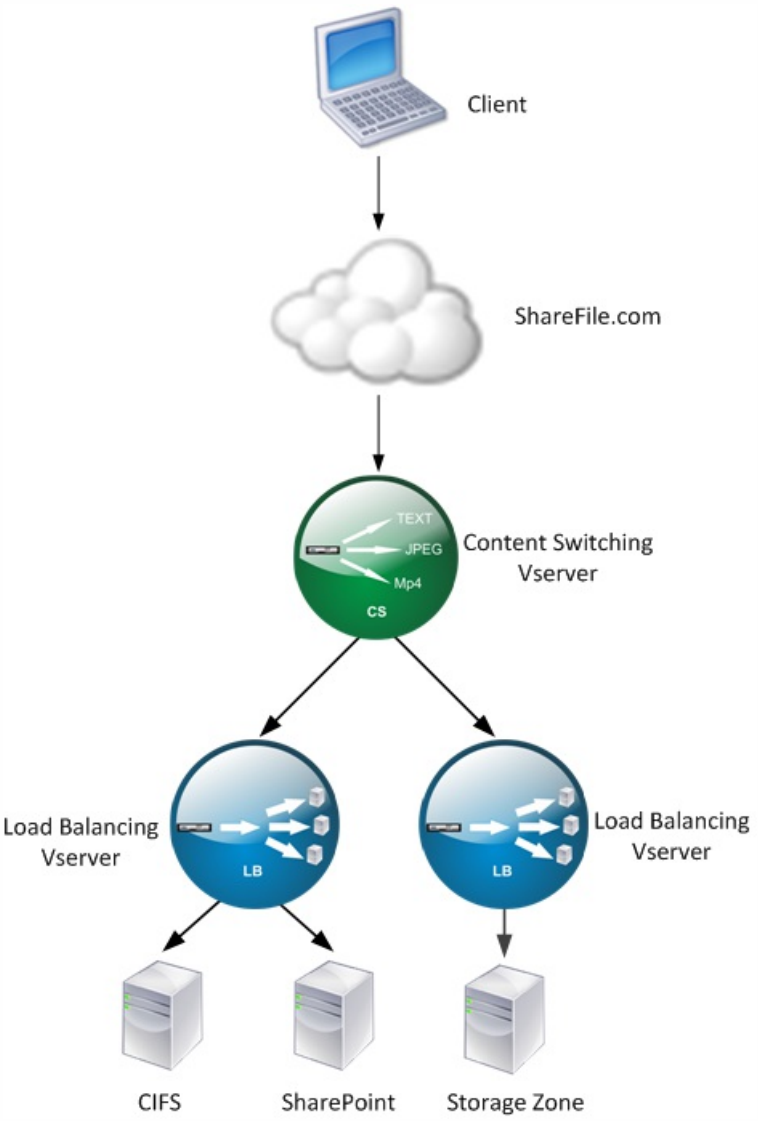
Use Case 14: ShareFile Wizard for Load Balancing Citrix ShareFile

Jun 08, 2015

You can configure load balancing for Citrix ShareFile using the wizard. The Citrix ShareFile wizard helps in setting up load balancing configuration for ShareFile site based on the type of content requested. The content switching server directs the request based on whether it is a StorageZone, CIFS or a SharePoint request. The content switching is based on policies. The wizard auto generates the policies to identify whether the request is for StorageZone, CIFS or SharePoint. The content switching virtual server uses these policies to direct the request to the correct load balancing server.

A typical data flow can be depicted as shown in the diagram below.

Figure 1. ShareFile Data Load Balancing



You can view the load balancing virtual servers that the ShareFile wizard creates by navigating to Traffic Management >Virtual Servers and Services > Virtual Servers. You cannot manually remove the virtual servers created using the ShareFile

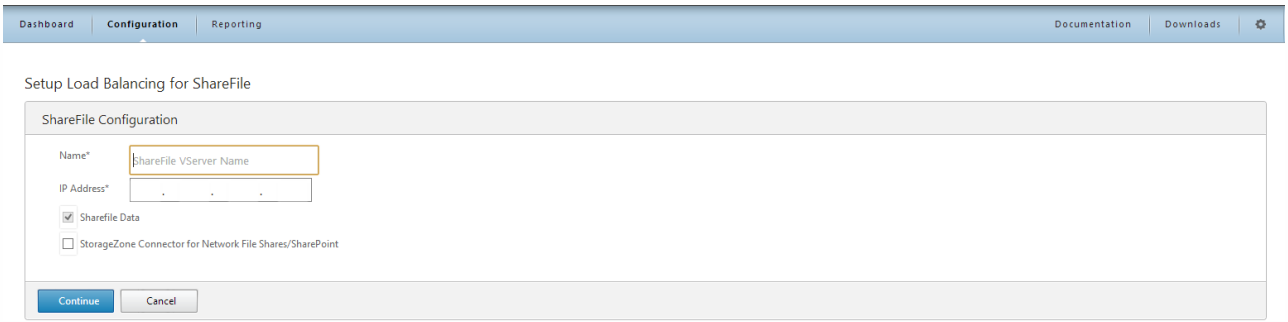
wizard. Use the wizard to remove the virtual servers.

NetScaler uses the LDAP authentication for SharePoint or CIFS request. Hash authentication is used for authenticating requests for StorageZones.

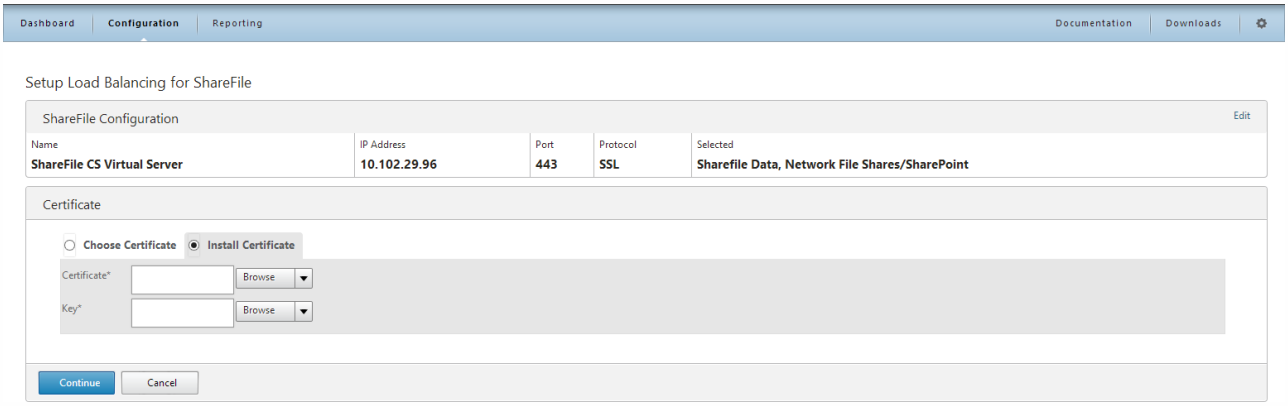
To configure a NetScaler appliance for load balancing Citrix ShareFile

Updated: 2015-06-04

1. In the navigation pane, click Load Balancing.
2. Navigate to Traffic Management > Load Balancing.
3. Under Citrix ShareFile, click Setup NetScaler for ShareFile.
4. On the Setup Load Balancing for ShareFile page, provide the following information:
   - Name: Name of the content switching virtual server.
   - IP Address: IP address of the content switching virtual server.
   - If you want to setup load balancing for CIFS or SharePoint, click the StorageZone Connector for Network File Shares/SharePoint checkbox and then click Continue. By default ShareFile Data checkbox is selected.

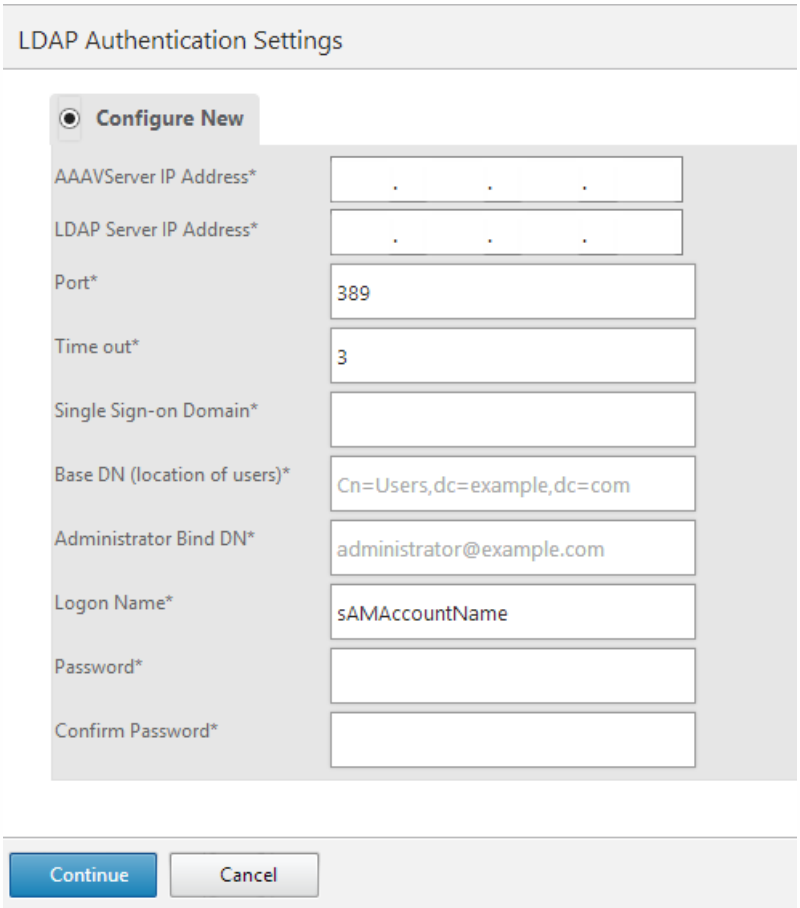


5. Provide a valid certificate. If you have a certificate, click Choose Certificate and from the drop-down list select the certificate. If you have to install a certificate, click Install Certificate and provide the Certificate-Key pair.



6. Click Continue.
7. In the Add New StorageZone Controller dialog box, specify the values of the following parameters:
   - StorageZone Controller IP Address— IP address
   - Port— Port number. The default value is 443.
   - Protocol— Select from HTTPS or HTTP

8. Click Create and then click Done. The wizard automatically creates a service and autogenerate the name of the service.
9. If you chose load balancing for CIFS or SharePoint in step 4.c, then specify the values for LDAP Authentication Settings:
   - AAAVServer IP Address— IP address of AAA virtual server
   - LDAP Server IP Address— IP Address of the LDAP server
   - Port— Port number. The default value is 389
   - Time out— The time out value in minutes
   - Single Sign-on Domain— Single sign-on domain name
   - Base DN— Base domain name
   - Administrator Bind DN— LDAP account name with the domain name, for example, adminstrator@domainname.com
   - Logon Name— Logon name is the sAMAccount name
   - Password and Confirm Password— Enter the password and confirm the password



10. Click Continue and then click Done.

To remove load balancing configuration for ShareFile

1. Click on Configuration > Traffic Management > Load Balancing.

2. On the Load Balancing page, under Citrix ShareFile click on Remove ShareFile Configuration.

Troubleshooting

Apr 26, 2017

If the load balancing does not work as expected after you have configured it, you can use some common tools to access NetScaler resources and diagnose the problem.

Resources for Troubleshooting Load Balancing

Updated: 2013-08-01

For best results, use the following resources to troubleshoot a content switching issue on a NetScaler appliance:

- Latest ns.conf file
- Relevant newnslog files
- Ethereal packet traces recorded on the appliance and relevant client, if possible
- The ns.log file

In addition to the above resources, the following tools expedite troubleshooting:

- A browser add-on tool that can display HTTP headers. This can be used to troubleshoot persistency related issues.
- The Wireshark application customized for the NetScaler trace files.

Troubleshooting Load Balancing Issues

Updated: 2015-06-11

- **Issue**

  CPU usage reaches 100% when a user monitor is bound to a service that is bound to a virtual server on which -m MAC option is enabled.

- **Resolution**

  Bind a non-user monitor to the service.

- **Issue**
  I created a user script for monitoring, but it is not working.

  Resolution

  Check the number of arguments in the script. The limit is 512. A script with more than 512 arguments might not work properly. Use the nsumon-debug.pl script from the NetScaler command line to debug the script.

- **Issue**
  I see a lot of monitor probes, and they seem to be increasing the network traffic unnecessarily. Is there a way to turn off the monitor probes?

  Resolution

  You can turn off the monitor probe connections, by disabling the monitor or setting the value of the healthMonitor parameter in the set service command to NO. With the NO option, the appliance shows the service as UP at all times.

- **Issue**
  I have set up monitors for services, but connections are still directed to servers that are DOWN.

Resolution

You probably need to decrease the monitor probe intervals. The NetScaler appliance does not detect the DOWN state until the monitor sends a probe.

- **Issue**
  A metric bound to the monitor is present in the local and custom metric tables.

  Resolution

  Add the local prefix to the metric name if the metric is chosen from the local metric table. However, if the metric is chosen from the custom table, you don't need to add any prefix.

- **Issue**
  The monitor probes to a service are not reaching the service.

  Resolution

  Check whether you have set a limit on the number of connections for a service. If yes, exempt monitor-probe connections from this limit by setting the monitorSkipMaxClient parameter to ENABLED.

- **Issue**
  I am able to ping the servers, but the state of the services is always shown as DOWN.

  Resolution

  Check the type of monitors configured. For example, if a server is not configured for SSL and you use an HTTPS monitor, the state of the service is marked as DOWN. In this case using a TCP monitor should change the state of the service to UP.

- **Issue**
  Setting a weight for load monitors does not help in deciding the state of the service.

  Resolution

  Load monitors cannot decide the state of the service. Therefore, setting a weight on the load monitors is inappropriate.

- **Issue**
  A service is not stable.

  Resolution

  Consider troubleshooting the following components:
  - Verify that a correct server is bound to the service.
  - Verify the type of monitor bound to the service.
  - Verify the reasons for the monitor failures. You can open service from the Services page and verify the details for the number of probes, failures, and last response status for the monitor in the Monitors tab of the Configure service dialog box. To display the details, click the monitor configured.
  - If it is a custom monitor, bind a TCP or ping monitor to the service and verify the status of the monitor. If this resolves the issue, there is some problem with the custom monitor and the monitor requires further investigation.
  - You can record packet traces on the NetScaler appliance and verify the monitor probes and server response for

further investigation.

- **Issue**
  The virtual IP (VIP) address is not stable or its status is displayed as DOWN.

  Resolution

  Consider troubleshooting the following components:
  - Verify that the load balancing feature is licensed.
  - Verify that the feature is enabled.
  - Verify that an appropriate service is bound to the virtual server.
  - If the status of the VIP address is displayed as DOWN, verify that an administrator has enabled the service. If it is not, the status of the service should be Out-Of-Service. In such as case, you must enable the service and verify if the issue is resolved.
  - Verify the service(s) bound to the virtual server and complete the troubleshooting steps mentioned for service not stable issue.
  - If the VIP address is not stable, all the services bound to the virtual server should fail. Therefore, verify if all the services are failing at the same time. If it is so, there is a network issue between the NetScaler appliance and the servers.

- **Issue**
  The site is experiencing uneven load balancing.

  Resolution

  Consider troubleshooting the following components:
  - Verify the load balancing method configured on the appliance.
  - Verify weights associated with the services are as expected.
  - If the load balancing method is other than round robin, verify the number of connections to the server logged in the newnslog file. You can run the following command to verify the number on the newnslog file:
    # nsconmsg –K <newnslog_file> -s ConLb=2 –d oldconmsg

    Verify the services for the specific virtual server and check for the Response time, Open Established connections (OE), Hits, Persistent Hits and persistent rate (P) to troubleshoot the issue further.

  - If the load balancing method is round robin, verify the persistent Hits as mentioned in the preceding step. Additionally, verify if the service is not stable. If it is not, complete the troubleshooting steps mentioned for service not stable issue
  - Verify if persistency is configured on the appliance.
  - Verify is any service is not stable. If yes, complete the troubleshooting steps mentioned for service not stable issue.

- **Issue**
  The service status is displayed as DOWN.

  Resolution

  Consider troubleshooting the following components:
  - Verify whether a SNIP or MIP address is configured.
  - Verify that appropriate monitors are bound to the service.
  - If custom monitors are bound to the service, bind a TCP or ping monitor to the service and verify the status of the monitor. If this resolves the issue, there is some problem with the custom monitor and the monitor requires further investigation.

- Verify if the status of service is displayed as DOWN for the server that is in another subnet. If yes, verify if Use Subnet IP (USNIP) resolves the issue because this could be due to the MIP address being unable to communicate to the server.

- **Issue**
  There is an issue with the response time.

  Resolution

  Consider troubleshooting the following components:
  - Verify the server response time from the service stats either by running the following command:
    # nsconmsg –K <newnslog_file> -s ConLb=2 –d oldconmsg
  - Check for service not stable and service status being displayed as DOWN issues.

- **Issue**
  One of the servers is serving more requests than the other load balanced servers.

  Resolution

  Consider troubleshooting the following components:

  - Verify the load balancing method. Use the round robin method to distribute the client request equally regardless of the load on the servers.
  - Determine whether persistence is enabled for the load balancing configuration. If persistence is enabled, a given servers might be carrying a heavier load to maintain its session, especially If the persistence sessions are long.
  - Verify whether weights are assigned to each service. Assigning proper weights helps in proper load distribution.

- **Issue**
  Connections to a specific load balanced server are stalled. For example, all connections to one Outlook server might be stalled.

  Resolution

  Consider troubleshooting the following components:
  - Verify the load balance method. If it is round robin, consider changing the method to least connections.
  - Consider reducing the monitor time-out period. A shorter timeout period helps in marking a service as DOWN sooner, which would help in directing the traffic to server which is functional.
  - If the connections are stalled for a long period, surge-queue might build. Consider flushing the surge-queue to avoid a sudden spike in load on the server.
  - If the servers are working at their maximum level, consider adding a new server for better performance.

- **Issue**
  A majority of the connections are directed to a particular server, even when the least connections method for load balancing is configured.

  Resolution

  Determine whether persistence is configured and is of type source IP. If source IP persistence is configured even with the least connections method, the requests go to a specific server. The server's IP address is required for maintaining the session information. Consider using HTTP Cookies based persistence.

- **Troubleshooting Tips**

  For other issues, consider following tips to troubleshoot an issue not listed above:
  - If multiple load monitors are bound to a service, the load on the service is the sum of all the values on the load monitors bound to it. For load balancing to work properly, you must bind the same set of monitors to all the services.
  - If you disable a load monitor bound to the service and the service is bound to a virtual server, the virtual server uses the round robin method for load balancing.
  - When you bind a service to a virtual server where the load balancing method is CUSTOMLOAD and the service status is UP, the virtual server uses the initial round robin method for load balancing. It continues to be in round robin if the service has no custom load monitors, or if status of at least one of the custom load monitors is not UP.
  - All the services that are bound to a virtual server where the load balancing method is CUSTOMLOAD, the services must have load monitors bound to them.
  - The CUSTOMLOAD load balancing method also follows startup round robin.
  - If you disable a metric-based binding and this is the last active metric, the specific virtual server uses the round robin method for load balancing. A metric is disabled by setting the metric threshold to zero.
  - When a metric bound to a monitor crosses the threshold value, that particular service is not considered for load balancing. If all the services have reached the threshold, the virtual server uses the round robin method for load balancing and an error message “5xx - server busy error” is displayed.
  - A maximum of 10 metrics from a custom table can be bound to the monitor.
  - The OIDs must be scalar variables.
  - For successful load balancing, the interval must be as low as possible. If the interval is high, the time period for retrieving the load value increases. As a result, load balancing takes place using improper values.
  - A user cannot modify the local table.

Load Balancing FAQ

Jul 01, 2016

What are the various load balancing policies I can create on the NetScaler appliance?

You can create the following types of load balancing policies on the NetScaler appliance:

- Least Connections
- Round Robin
- Least response time
- Least bandwidth
- Least packets
- URL hashing
- Domain name hashing
- Source IP address hashing
- Destination IP address hashing
- Source IP - Destination IP hashing
- Token
- LRTM

Can I achieve the Web farm security by implementing load balancing using the NetScaler appliance?

Yes. You can achieve Web farm security by implementing load balancing using the NetScaler appliance. NetScaler appliance enables you to implement the following options of the load balancing feature:

- IP Address hiding: Enables you to install the actual servers to be on private IP address space for security reasons and for IP address conservation. This process is transparent to the end-user because the NetScaler appliance accepts requests on behalf of the server. While in the address hiding mode, the appliance completely isolates the two networks. Therefore, a client can access a service running on the private subnet, such as FTP or a Telnet server, through a different VIP on the appliance for that service.
- Port Mapping: Enables the actual TCP services to be hosted on non-standard ports for security reasons. This process is transparent to the end-user as the NetScaler appliance accepts requests on behalf of the server on the standard advertised IP address and port number.

What are various devices that I can use to load balance with a NetScaler appliance?

You can load balance following devices with a NetScaler appliance:

- Server farms
- Caches or Reverse Proxies
- Firewall devices
- Intrusion detection systems
- SSL offload devices
- Compression devices
- Content Inspection servers

Why should I implement the load balancing feature for the website?

You can implement the Load balancing feature for the website to take the following advantages:

- Reduce the response time: When you implement the load balancing feature for the website, one of the major benefits is the boost you can look forward to in load time. With two or more servers sharing the load of the web traffic, each of the servers runs less traffic load than a single server alone. This means there are more resources available to fulfill the client requests. This results in a faster website.

- Redundancy: Implementing the load balancing feature introduces a bit of redundancy. For example, if the website is balanced across three servers and one of them does not respond at all, the other two can keep running and the website visitors do not even notice any downtime. Any load balancing solution immediately stops sending traffic to the backend server that is not available.

Why do I need to disable the Mac Based Forwarding (MBF) option for Link Load Balancing (LLB)?

- If you enable the MBF option, the NetScaler appliance considers that the incoming traffic from the client and the outgoing traffic to the same client flow through the same upstream router. However, the LLB feature requires that the best path be chosen for the return traffic.
- Enabling the MBF option breaks this topology design by sending the outgoing traffic through the router that forwarded the incoming client traffic.

Networking

May 13, 2016

The following topics provide a conceptual reference and instructions for configuring the various networking components on the NetScaler appliance.

IP Addressing	Learn the various types of NetScaler-owned IP addresses and how to create, customize, and remove them.
Interfaces	Configure some of the basic network configurations that must be done to get started.
Access Control Lists (ACLs)	Configure the different types of Access Control Lists and how to create, customize, and remove them.
IP Routing	Learn and configure the routing functionality of the NetScaler appliance, both static and dynamic.
Internet Protocol version 6 (IPv6)	Learn how the NetScaler appliance supports IPv6.
Traffic Domains	Learn and configure traffic domains to segment network traffic for different applications.
VXLAN	Learn and configure VXLANs to meet the scalability needs in your datacenter.

IP Addressing

Aug 28, 2013

Before you can configure the NetScaler appliance, you must assign the NetScaler IP Address (NSIP), also known as the Management IP address. You can also create other NetScaler-owned IP addresses for abstracting servers and establishing connections with the servers. In this type of configuration, the appliance serves as a proxy for the abstracted servers. You can also proxy connections by using network address translations (INAT and RNAT). When proxying connections, the appliance can behave either as a bridging (Layer 2) device or as a packet forwarding (Layer 3) device. To make packet forwarding more efficient, you can configure static ARP entries. For IPv6, you can configure neighbor discovery (ND).

This document includes the following information:

Configuring NetScaler-Owned IP Addresses

Mar 20, 2012

The NetScaler-owned IP Addresses—NetScaler IP Address (NSIP), Virtual IP Addresses (VIPs), Subnet IP Addresses (SNIPs), Mapped IP Addresses (MIPs), and Global Server Load Balancing Site IP Addresses (GSLBIPs)—exist only on the NetScaler appliance. The NSIP uniquely identifies the NetScaler on your network, and it provides access to the appliance. A VIP is a public IP address to which a client sends requests. The NetScaler terminates the client connection at the VIP and initiates a connection with a server. This new connection uses a SNIP or a MIP as the source IP address for packets forwarded to the server. If you have multiple data centers that are geographically distributed, each data center can be identified by a unique GSLBIP.

You can configure some NetScaler-owned IP addresses to provide access for management applications.

This document includes the following information:

- Configuring the NetScaler IP Address (NSIP)
- Configuring and Managing Virtual IP (VIP) Addresses
- Configuring ARP response Suppression for Virtual IP addresses (VIPs)
- Configuring Subnet IP Addresses (SNIPs)
- Configuring Mapped IP Addresses (MIPs)
- Configuring GSLB Site IP Addresses (GSLBIP)
- Removing a NetScaler-Owned IP Address
- Configuring Application Access Controls

Configuring the NetScaler IP Address (NSIP)

Jul 07, 2016

The NetScaler IP (NSIP) address is the IP address at which you access the NetScaler appliance for management purposes. The appliance can have only one NSIP, which is also called the management IP address. You must add this IP address when you configure the NetScaler for the first time. You cannot remove an NSIP address. For security reasons, the NSIP should be a non-routable IP address on your organization's LAN.

If you modify this address, you must reboot the NetScaler appliance. If the subnet address of the new NSIP address is different from the previous one, you must add a default route for this subnet so that the new NSIP address becomes reachable from other networks on the LAN.

> **Important**
>
> Configuring the NetScaler IP address is mandatory.

Changing the NSIP address of a NetScaler appliance consists of the following tasks:

- Change the NSIP address.
- Add a default route for the subnet address of the NSIP address, if one is not present.
- Save the configuration.
- Restart the appliance.

Command Line Procedures

To change the NetScaler IP address by using the NetScaler command line

At the command prompt, type:

- **set ns config -IPAddress** <ip_addr> **-netmask** <netmask>
- **show ns config**

To add a default route by using the command line interface

At the command prompt, type:

- **add route 0 0** <gateway IP address>
- **show route**

To save the configuration by using the NetScaler command line

At the command prompt, type:

- **save config**

To restart the NetScaler appliance by using the NetScaler command line

At the command prompt, type:

- **reboot**

GUI Procedures

To configure the NetScaler IP address by using the NetScaler GUI

1. Click the gear icon in the top-right corner of the **Configuration** page.
2. Click the **NetScaler IP address** pane.
3. On the **NetScaler IP Address** page, set the following parameters, and then click **Done**:
   - NetScaler IP Address
   - Netmask

To add a default route by using the NetScaler GUI

Navigate to **System** > **Network** > **Routes** and, on the **Basic** tab, add a default route with the following parameter settings, and then click **Create**.

- Network (set to zero)
- Netmask (set to zero)
- Gateway (IP address of the gateway)

To restart the NetScaler by using the NetScaler GUI

1. On the **System Information** tab page of the **System** node, click **Reboot**.
2. When prompted to reboot, select **Save Configuration** to make sure that you do not lose any configurations.

Example

In the following example, the NSIP address of a NetScaler appliance is changed to 192.0.2.90, which has a different subnet address (192.0.2.0/24) than the previous NSIP address. Therefore, a default route is added for this subnet, so that the new NSIP address becomes reachable from other networks.

Example COPY

```
> set nsconfig -ipAddress 192.0.2.90 -netmask 255.255.255.0

 Warning: The configuration must be saved and the system rebooted for these settings to take effect

> add route 0 0 192.0.2.1

 Warning: The configuration must be saved and the system rebooted for these settings to take effect

> save config

 Done

> reboot
```

Configuring and Managing Virtual IP (VIP) Addresses

Nov 23, 2015

Configuration of a virtual server IP (VIP) address is not mandatory during initial configuration of the NetScaler ADC. When you configure load balancing, you assign VIP addresses to virtual servers.

For more information about configuring a load balancing setup, see "Load Balancing."

In some situations, you need to customize VIP attributes or enable or disable a VIP address. A VIP address is usually associated with a virtual server, and some of the VIP attributes are customized to meet the requirements of the virtual server. You can host the same virtual server on multiple NetScaler appliances residing on the same broadcast domain, by using ARP and ICMP attributes. After you add a VIP (or any IP address), the NetScaler sends, and then responds to, ARP requests. VIPs are the only NetScaler-owned IP addresses that can be disabled. When a VIP address is disabled, the virtual server using it goes down and does not respond to ARP, ICMP, or L4 service requests.

As an alternative to creating VIP addresses one at a time, you can specify a consecutive range of VIP addresses.

To create a VIP address by using the command line interface

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type <type>
- show ns ip <IPAddress>

Example

```
> add ns ip 10.102.29.59 255.255.255.0 -type VIP
 Done
```

To create a range of VIP addresses by using the command line interface

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type <type>
- show ns ip <IPAddress>

Example

```
> add ns ip 10.102.29.[60-64] 255.255.255.0 -type VIP
ip "10.102.29.60" added
ip "10.102.29.61" added
ip "10.102.29.62" added
ip "10.102.29.63" added
ip "10.102.29.64" added
 Done
```

To configure a VIP address by using the configuration utility

Navigate to System > Network > IPs > IPV4s, and add a new IP address or edit an existing address.

To create a range of VIP addresses by using the configuration utility

1. Navigate to System > Network > IPs > IPV4s.
2. In the Action list, select Add Range.

To enable or disable an IPv4 VIP address by using the command line interface

At the command prompt, type one of the following sets of commands to enable or disable a VIP and verify the configuration:

- enable ns ip <IPAddress>
- show ns ip <IPAddress>
- disable ns ip <IPAddress>
- show ns ip <IPAddress>

Example

```
> enable ns ip 10.102.29.79
 Done
> show ns ip 10.102.29.79

      IP: 10.102.29.79
      Netmask: 255.255.255.255
      Type: VIP
      state: Enabled
      arp: Enabled
      icmp: Enabled
      vserver: Enabled
      management access: Disabled
        telnet: Disabled
        ftp: Disabled
        ssh: Disabled
        gui: Disabled
        snmp: Disabled
      Restrict access: Disabled
      dynamic routing: Disabled
      hostroute: Disabled
 Done
> disable ns ip 10.102.29.79
 Done
> show ns ip 10.102.29.79

      IP: 10.102.29.79
      Netmask: 255.255.255.255
      Type: VIP
      state: Disabled
      arp: Enabled
      icmp: Enabled
      vserver: Enabled
      management access: Disabled
        telnet: Disabled
```

ftp: Disabled
ssh: Disabled
gui: Disabled
snmp: Disabled
Restrict access: Disabled
dynamic routing: Disabled
hostroute: Disabled

Done

To enable or disable a VIP address by using the configuration utility

1. Navigate to **System** > **Network** > **IPs** > **IPV4s**.
2. Do one of the following:
   - Select a VIP address.
   - Hold down the **Ctrl** key and select multiple server address entries.
   - Hold down the **Shift** key and select a range of server address entries.
   - Select all the addresses by selecting the checkbox on the left side of the header row.
3. From the **Action** list, select **Disable** or **Enable**.

Configuring ARP response Suppression for Virtual IP addresses (VIPs)

Aug 28, 2013

You can configure the NetScaler appliance to respond or not respond to ARP requests for a Virtual IP (VIP) address on the basis of the state of the virtual servers associated with that VIP.

For example, if virtual servers V1, of type HTTP, and V2, of type HTTPs, share VIP address 10.102.29.45 on a NetScaler appliance, you can configure the appliance to not respond to any ARP request for VIP 10.102.29.45 if both V1 and V2 are in the DOWN state.

The following three options are available for configuring ARP-response suppression for a virtual IP address.

- **NONE**. The NetScaler appliance responds to any ARP request for the VIP address, irrespective of the state of the virtual servers associated with the address.
- **ONE VSERVER**. The NetScaler appliance responds to any ARP request for the VIP address if at least one of the associated virtual servers is in UP state.
- **ALL VSERVER**. The NetScaler appliance responds to any ARP request for the VIP address if all of the associated virtual servers are in UP state.

Following table shows the sample behavior of NetScaler appliance for a VIP configured with two virtual servers:

Associated virtual servers for a VIP	**STATE 1**	**STATE 2**	**STATE 3**	**STATE 4**
NONE				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Respond to an ARP request for this VIP?	Yes	Yes	Yes	Yes
ONE VSERVER				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Respond to an ARP request for this VIP?	Yes	Yes	Yes	No
ALL VSERVER				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Respond to an ARP request for this VIP?	Yes	No	No	No

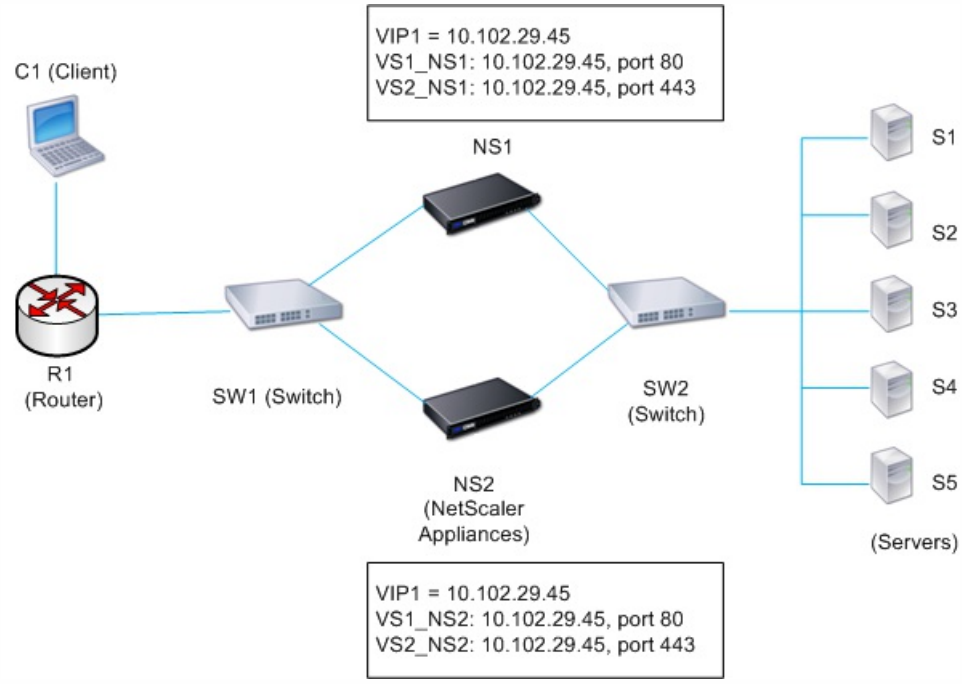
Consider an example where you want to test the performance of two virtual servers, V1 and V2, which have the same VIP address but are of different types and are each configured on NetScaler appliances NS1 and NS2. Let's call the shared VIP

address *VIP1*.

V1 load balances servers S1, S2, and S3. V2 load balances servers S4 and S5.

On both NS1 and NS2, for VIP1, the ARP suppression parameter is set to ALL_VSERVER. If you want to test the performance of V1 and V2 on NS1, you must manually disable V1 and V2 on NS2, so that NS2 does not respond to any ARP request for VIP1.

Figure 1.



The execution flow is as follows:

1. Client C1 sends a request to V1. The request reaches R1.
2. R1 does not have an APR entry for the IP address (VIP1) of V1, so R1 broadcasts an ARP request for VIP1.
3. NS1 replies with source MAC address MAC1 and source IP address VIP1. NS2 does not reply to the ARP request.
4. SW1 learns the port for VIP1 from the ARP reply and updates its bridge table, and R1 updates the ARP entry with MAC1 and VIP1.
5. R1 forwards the packet to address VIP1 on NS1.
6. NS1's load balancing algorithm selects server S2, and NS1 opens a connection between one of its SNIP or MIP addresses and S2. When S2 sends a response to the client, the response returns by the same path.
7. Now you want to test the performance of V1 and V2 on NS2, so you enable V1 and V2 on NS2 and disable them on NS1. NS2 now broadcasts an ARP message for VIP1. In the message, MAC2 is the source MAC address and VIP1 is the source IP address.
8. SW1 learns the port number for reaching MAC2 from the ARP broadcast and updates its bridge table to send subsequent client requests for VIP1 to NS2. R1 updates its ARP table.
9. Now suppose the ARP entry for VIP1 times out in the ARP table of R1, and client C1 sends a request for V1. Because R1 does not have an APR entry for VIP1, it broadcasts an ARP request for VIP1.
10. NS2 replies with a source MAC address and VIP1 as the source IP address. NS1 does not reply to the ARP request.

To configure ARP response suppression by using the command line interface

At the command prompt, type:

- set ns ip -arpResponse <arpResponse>]
- show ns ip <IPAddress>

Example

```
> set ns ip 10.102.29.96 -arpResponse ALL_VSERVERS
 Done
```

To configure ARP response suppression by using the configuration utility

1. Navigate to System > Network > IPs > IPV4s.
2. Open an IP address entry and select the type of ARP Response.

Configuring Subnet IP Addresses (SNIPs)

May 23, 2014

A subnet IP address (SNIP) is a NetScaler owned IP address that is used by the NetScaler ADC to communicate with the servers.

The NetScaler ADC uses the subnet IP address as a source IP address to proxy client connections to servers. It also uses the subnet IP address when generating its own packets, such as packets related to dynamic routing protocols, or to send monitor probes to check the health of the servers.

Depending on your network topology, you might have to configure one or more SNIPs for different scenarios. Following are three typical scenarios in which you have to configure SNIPs:

- Using SNIPs for a Directly Connected Server Subnet
- Using SNIPs for Server Subnets Connected through a Router
- Using SNIPs for Multiple Server Subnets (VLANs) on an L2 Switch

To configure a SNIP address on a NetScaler ADC, you add the SNIP address and then enable global Use Subnet IP (USNIP) mode.

As an alternative to creating SNIPs one at a time, you can specify a consecutive range of SNIPs.

To configure a SNIP address by using the command line interface

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type SNIP
- show ns ip <IPAddress>

Example

```
> add ns ip 10.102.29.203 255.255.255.0 -type SNIP
 Done
```

To create a range of SNIP addresses by using the command line interface

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type SNIP
- show ns ip <IPAddress>

Example

```
> add ns ip 10.102.29.[205-209] 255.255.255.0 -type SNIP
ip "10.102.29.205" added
ip "10.102.29.206" added
ip "10.102.29.207" added
ip "10.102.29.208" added
ip "10.102.29.209" added
 Done
```

To enable or disable USNIP mode by using the command line interface

At the command prompt, type one of the following commands:

- enable ns modeUSNIP
- disable ns modeUSNIP

To configure a SNIP address by using the configuration utility

Navigate to System > Network > IPs > IPV4s, and add a new SNIP address or edit an existing address.

To create a range of SNIP addresses by using the configuration utility

1. Navigate to System > Network > IPs > IPV4s.
2. In the Action list, select Add Range.

To enable or disable USNIP mode by using the command line interface

At the command prompt, type one of the following commands:

- enable ns mode USNIP
- disable ns mode USNIP

To enable or disable USNIP mode by using the configuration utility

1. Navigate to System > Settings, in Modes and Features group, click Change modes.
2. Select or clear the Use Subnet IP option.

Using SNIPs for a Directly Connected Server Subnet

Updated: 2014-05-23

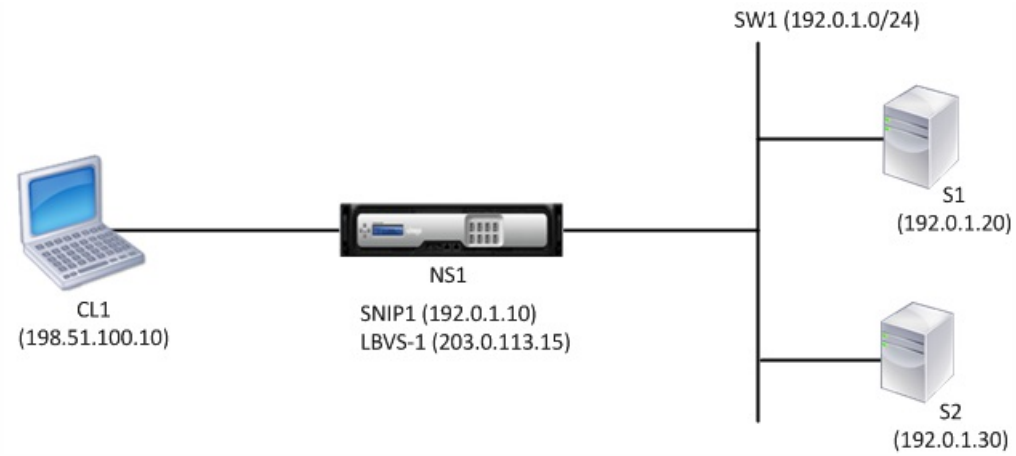
To enable communication between the NetScaler and a server that is either connected directly to the NetScaler or connected through only an L2 switch, you must configure a subnet IP address that belongs to the subnet of the server. You must configure at least one subnet IP address for each directly connected subnet, except for the directly connected management subnet that is connected through NSIP.

Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on NetScaler ADC NS1 is used to load balance servers S1 and S2, which are connected to NS1 through L2 switch SW1. S1 and S2 belong to the same subnet.

SNIP address SNIP1, which belongs to the same subnet as S1 and S2, is configured on NS1. As soon as SNIP1 is configured, NS1 broadcasts ARP packets for SNIP1.

Services SVC-S1 and SVC-S2 on NS1 represent S1 and S2. As soon as these services are configured, NS1 broadcasts ARP requests for S1 and S2 to resolve IP-to-MAC mapping. After S1 and S2 respond, NS1 sends them monitoring probes at regular intervals, from address SNIP1, to check their health.

For more information about configuring load balancing on a NetScaler ADC, see Load Balancing.



Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
   - Source IP = IP address of the client (198.51.100.10)
   - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1's load balancing algorithm selects server S2.
4. Because S2 is directly connected to NS1, and SNIP1 (192.0.1.10) is the only IP address on NS1 that belongs to the same subnet as S2, NS1 opens a connection between SNIP1 and S2.
5. NS1 sends the request packet to S2 from SNIP1. The request packet has:
   - Source IP = SNIP1 (192.0.1.10)
   - Destination IP = IP address of S2 (192.0.1.30)
6. S2's response returns by the same path.

Using SNIPs for Server Subnets Connected through a Router

Updated: 2014-05-23

To enable communication between the NetScaler ADC and servers in subnets connected through a router, you must configure at least one subnet IP address that belongs to the subnet of the directly connected interface to the router. The ADC uses this subnet IP address to communicate with servers in subnets that can be reached through the router.

Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on NetScaler ADC NS1 is used to load balance servers S1, S2, S3, and S4, which are connected to NS1 through router R1.

S1 and S2 belong to same subnet, 192.0.2.0/24, and are connected to R1 through L2 switch SW1. S3 and S4 belong to a different subnet, 192.0.3.0/24, and are connected to R1 through L2 switch SW2.

NetScaler ADC NS1 is connected to router R1 through subnet 192.0.1.0/24. SNIP address SNIP1, which belongs to the same subnet as the directly connected interface to the router (192.0.1.0/24), is configured on NS1. NS1 uses this address to communicate with servers S1 and S2, and with servers S3 and S4.

For more information about configuring load balancing on a NetScaler ADC, see Load Balancing.

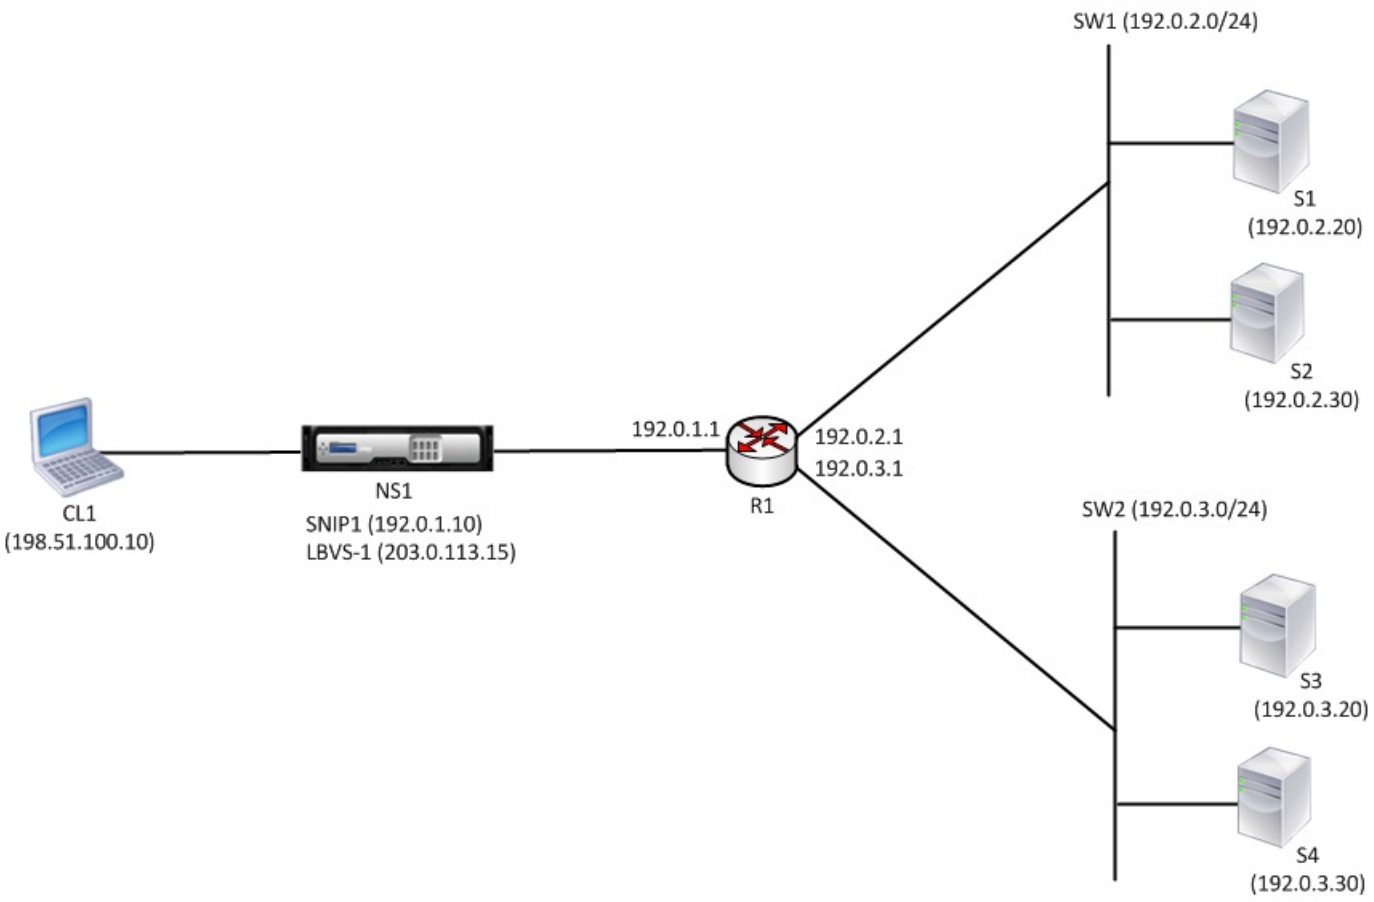
As soon as address SNIP1 is configured, NS1 broadcasts ARP announcement packets for SNIP1.

NS1's routing table consists of route entries for S1, S2, S3, and S4 through R1. These route entries are either static route entries or advertised by R1 to NS1, using dynamic routing protocols.

Services SVC-S1, SVC-S2, SVC-S3, and SVC-S4 on NS1 represent servers S1, S2, S3, and S4. NS1 finds, in its routing tables,

that these servers are reachable through R1. NS1 sends them monitoring probes at regular intervals, from address SNIP1, to check their health.

For more information about IP routing on a NetScaler ADC, see IP Routing.



Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
   - Source IP = IP address of the client (198.51.100.10)
   - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1's load balancing algorithm selects server S3.
4. NS1 checks its routing table and finds that S3 is reachable through R1. SNIP1 (192.0.1.10) is the only IP address on NS1 that belongs to the same subnet as router R1, NS1 opens a connection between SNIP1 and S3 through R1.
5. NS1 sends the request packet to R1 from SNIP1. The request packet has:
   - Source IP address = SNIP1 (192.0.1.10)
   - Destination IP address = IP address of S3 (192.0.3.20)
6. The request reaches R1, which checks its routing table and forwards the request packet to S3.
7. S3's response returns by the same path.

Using SNIPs for Multiple Server Subnets (VLANs) on an L2 Switch

Updated: 2014-05-23

When you have multiple server subnets (VLANs) on an L2 switch that is connected to a NetScaler ADC, you must configure at least one SNIP address for each of the server subnets, so that the NetScaler ADC can communicate with these server subnets.

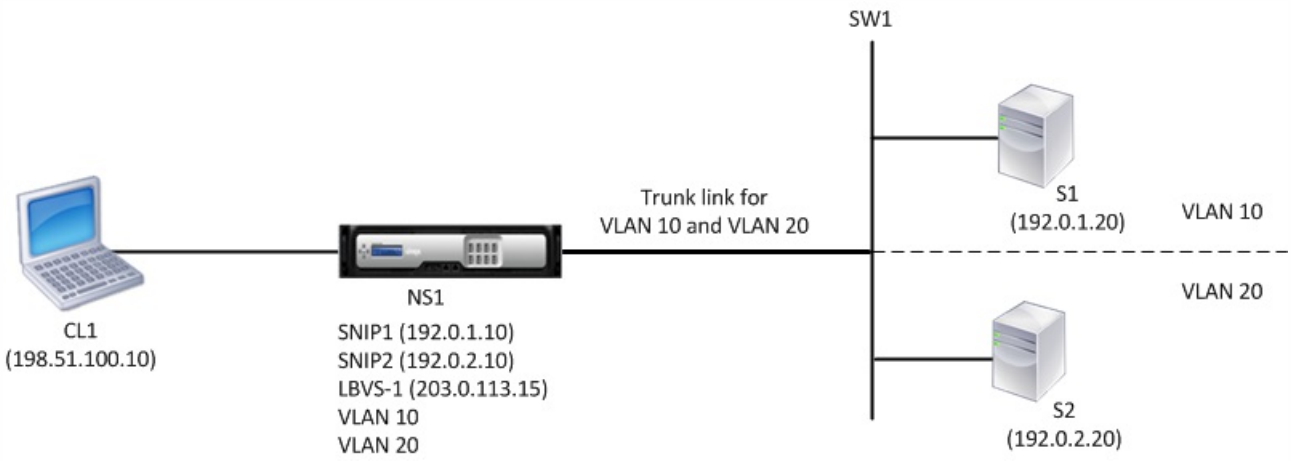
Consider an example of a load balancing setup in which load balancing virtual server LBVS1 on NetScaler ADC NS1 is used to load balance servers S1 and S2, which are connected to NS1 through L2 switch SW1. S1 and S2 belong to different subnets and are part of VLAN 10 and VLAN20, respectively. The link between NS1 and SW1 is a trunk link and is shared by VLAN10 and VLAN20.

For more information about configuring load balancing on a NetScaler ADC, see Load Balancing.

Subnet IP addresses SNIP1 (for reference purposes only) and SNIP2 (for reference purposes only) are configured on NS1. NS1 uses SNIP1 (on VLAN 10) to communicate with server S1, and SNIP2 (on VLAN 20) to communicate with S2. As soon as SNIP1 and SNIP2 are configured, NS1 broadcasts ARP announcement packets for SNIP1 and SNIP2.

For more information about configuring VLANs on a NetScaler ADC, see Configuring a VLAN.

Services SVC-S1 and SVC-S2 on NS1 represent servers S1 and S2. As soon as these services are configured, NS1 broadcasts ARP requests for them. After S1 and S2 respond, NS1 sends them monitoring probes at regular intervals to check their health. NS1 sends monitoring probes to S1 from address SNIP1, and to S2 from address SNIP2.



Following is the traffic flow in this example:

1. Client C1 sends a request packet to LBVS-1. The request packet has:
   - Source IP = IP address of the client (198.51.100.10)
   - Destination IP = IP address of LBVS-1 (203.0.113.15)
2. LBVS1 of NS1 receives the request packet.
3. LBVS1's load balancing algorithm selects server S2.
4. Because S2 is directly connected to NS1, and SNIP2 (192.0.2.10) is the only IP address on NS1 that belongs to the same subnet as S2, NS1 opens a connection between SNIP2 and S2.
   Note: If S1 is selected, NS1 opens a connection between SNIP1 and S1.
5. NS1 sends the request packet to S2 from SNIP2. The request packet has:
   - Source IP = SNIP1 (192.0.2.10)
   - Destination IP = IP address of S2 (192.0.2.20)
6. S2's response returns by the same path.

Configuring Mapped IP Addresses (MIPs)

Sep 30, 2013

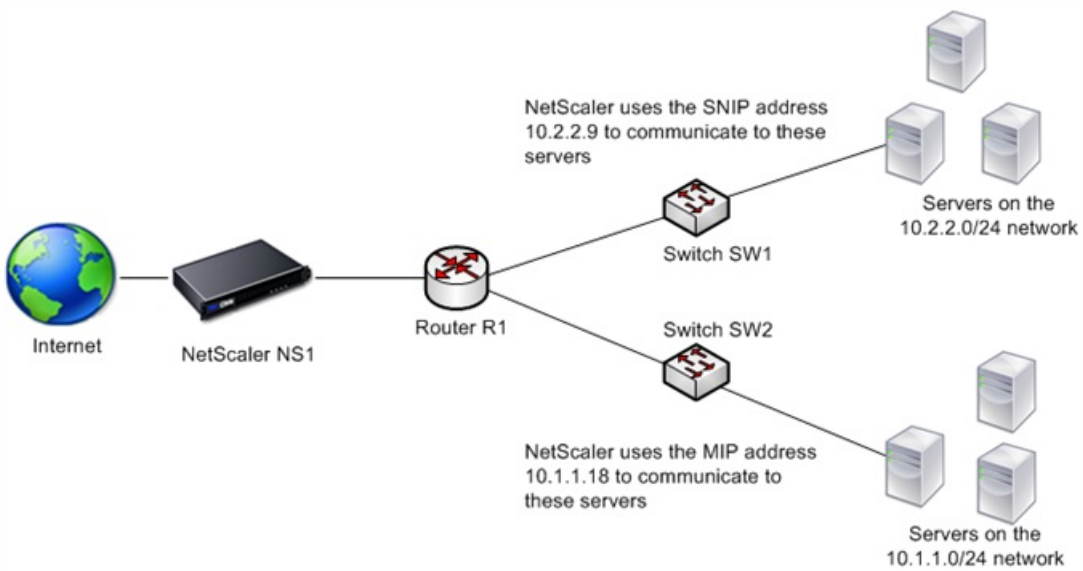
Mapped IP addresses (MIP) are used for server-side connections. A MIP can be considered a default Subnet IP (SNIP) address, because MIPs are used when a SNIP is not available or Use SNIP (USNIP) mode is disabled.

If the mapped IP address is the first in the subnet, the NetScaler appliance adds a route entry, with this IP address as the gateway to reach the subnet. You can create or delete a MIP during run time without rebooting the appliance.

As an alternative to creating MIPs one at a time, you can specify a consecutive range of MIPs.

The following diagram shows the use of the MIP and SNIP addresses in a NetScaler appliance that connects to the backend servers across the subnets.

Figure 1. MIP and SNIP addresses



In the setup, if the NetScaler appliance and the backend servers are in the 10.1.1.0/24 subnet, then the appliance uses the MIP address to communicate to the servers. However, if the setup has backend servers on additional subnets, such as 10.2.2.0/24, and there is no router between the NetScaler appliance and the subnet, then you can configure a SNIP address that has a range of 10.2.2.x/24, such as 10.2.2.9 in this case, to communicate to the additional subnet.

You can enable to NetScaler appliance to use MIP to communicate the additional subnet. However, if the setup has a Firewall application between the appliance and the server, then the Firewall might prevent the traffic other than 10.2.2.0/24. In such cases, you need a SNIP address to communicate to the servers.

To create a MIP address by using the command line interface

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type <type>
- show ns ip <IPAddress>

Example

```
> add ns ip 10.102.29.171 255.255.255.0 -type MIP
 Done
```

To create a range of MIP addresses by using the command line interface

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type <type>
- show ns ip <IPAddress>

Example

```
> add ns ip 10.102.29.[173-175] 255.255.255.0 -type MIP
ip "10.102.29.173" added
ip "10.102.29.174" added
ip "10.102.29.175" added
Done
```

To configure a MIP address by using the configuration utility

Navigate to System > Network > IPs > IPV4s, and add a new MIP address or edit an existing address.

To create a range of MIP addresses by using the configuration utility

1. Navigate to System > Network > IPs > IPV4s.
2. In the Action list, select Add Range.

Configuring GSLB Site IP Addresses (GSLBIP)

Aug 28, 2013

A GSLB site IP (GSLBIP) address is an IP address associated with a GSLB site. It is not mandatory to specify a GSLBIP address when you initially configure the NetScaler appliance. A GSLBIP address is used only when you create a GSLB site.

For more information about creating a GSLB site IP address, see "Global Server Load Balancing."

Removing a NetScaler-Owned IP Address

Aug 28, 2013

You can remove any IP address except the NSIP. The following table provides information about the processes you must follow to remove the various types of IP addresses. Before removing a VIP, remove the associated virtual server.

Table 1. Implications of Removing a NetScaler-Owned IP Address

IP address type	Implications
Subnet IP address (SNIP)	If IP address being removed is the last IP address in the subnet, the associated route is deleted from the route table. If the IP address being removed is the gateway in the corresponding route entry, the gateway for that subnet route is changed to another NetScaler-owned IP address.
Mapped IP address (MIP)	If a SNIP exists, you can remove the MIPs. The NetScaler uses NSIP and SNIPs to communicate with the servers when the MIP is removed. Therefore, you must also enable use SNIP (USNIP) mode. For information about enabling and disabling USNIP mode, see "Configuring Subnet IP Addresses (SNIPs)."
Virtual Server IP address (VIP)	Before removing a VIP, you must first remove the vserver associated with it. For information about removing the vserver, see "Load Balancing."
GSLB-Site-IP address	Before removing a GSLB site IP address, you must remove the site associated with it. For information about removing the site, see "Global Server Load Balancing."

To remove an IP address by using the command line interface

At the command prompt, type:

rm ns ip <IPaddress>

Example

```
rm ns ip 10.102.29.54
```

To remove an IP address by using the configuration utility

Navigate to System > Network > IPs > IPV4s, delete the IP address.

Configuring Application Access Controls

Sep 30, 2015

Application access controls, also known as management access controls, form a unified mechanism for managing user authentication and implementing rules that determine user access to applications and data. You can configure MIPs and SNIPs to provide access for management applications. Management access for the NSIP is enabled by default and cannot be disabled. You can, however, control it by using ACLs.

For information about using ACLs, see Access Control Lists (ACLs).

The NetScaler appliance does not support management access to VIPs.

The following table provides a summary of the interaction between management access and specific service settings for Telnet.

Management Access	Telnet (State Configured on the NetScaler)	Telnet (Effective State at the IP Level)
Enable	Enable	Enable
Enable	Disable	Disable
Disable	Enable	Disable
Disable	Disable	Disable

The following table provides an overview of the IP addresses used as source IP addresses in outbound traffic.

Application/ IP	NSIP	MIP	SNIP	VIP
ARP	Yes	Yes	Yes	No
Server side traffic	No	Yes	Yes	No
RNAT	No	Yes	Yes	Yes
ICMP PING	Yes	Yes	Yes	No
Dynamic routing	Yes	No	Yes	Yes

The following table provides an overview of the applications available on these IP addresses.

Application/ IP	NSIP	MIP	SNIP	VIP
SNMP	Yes	Yes	Yes	Yes
System access	Yes	Yes	Yes	No

You can access and manage the NetScaler by using applications such as Telnet, SSH, GUI, and FTP.

Note: Telnet and FTP are disabled on the NetScaler for security reasons. To enable them, contact the customer support. After the applications are enabled, you can apply the controls at the IP level.
To configure the NetScaler to respond to these applications, you need to enable the specific management applications. If you disable management access for an IP address, existing connections that use the IP address are not terminated, but no new connections can be initiated.

Also, the non-management applications running on the underlying FreeBSD operating system are open to protocol attacks, and these applications do not take advantage of the NetScaler appliance's attack prevention capabilities.

You can block access to these non-management applications on a MIP, SNIP, or NSIP. When access is blocked, a user connecting to a NetScaler by using the MIP, SNIP, or NSIP is not be able to access the non-management applications running on the underlying operating system.

To configure management access for an IP address by using the command line interface

At the command prompt, type:

set ns ip <IPAddress> -mgmtAccess <value> -telnet <value> -ftp <value> -gui <value> -ssh <value> -snmp <value> -restrictAccess (ENABLED | DISABLED)

Example

```
> set ns ip 10.102.29.54 -mgmtAccess enabled -restrictAccess ENABLED
 Done
```

To enable management access for an IP address by using the configuration utility

1. Navigate to System > Network > IPs > IPV4s.
2. Open an IP address entry, and select the Enable Management Access control to support the below listed applications option.

How the NetScaler Proxies Connections

Aug 28, 2013

When a client initiates a connection, the NetScaler appliance terminates the client connection, initiates a connection to an appropriate server, and sends the packet to the server. The appliance does not perform this action for service type UDP or ANY.

For more information about service types, see "Load Balancing."

You can configure the NetScaler to process the packet before initiating the connection with a server. The default behavior is to change the source and destination IP addresses of a packet before sending the packet to the server. You can configure the NetScaler to retain the source IP address of the packets by enabling Use Source IP mode.

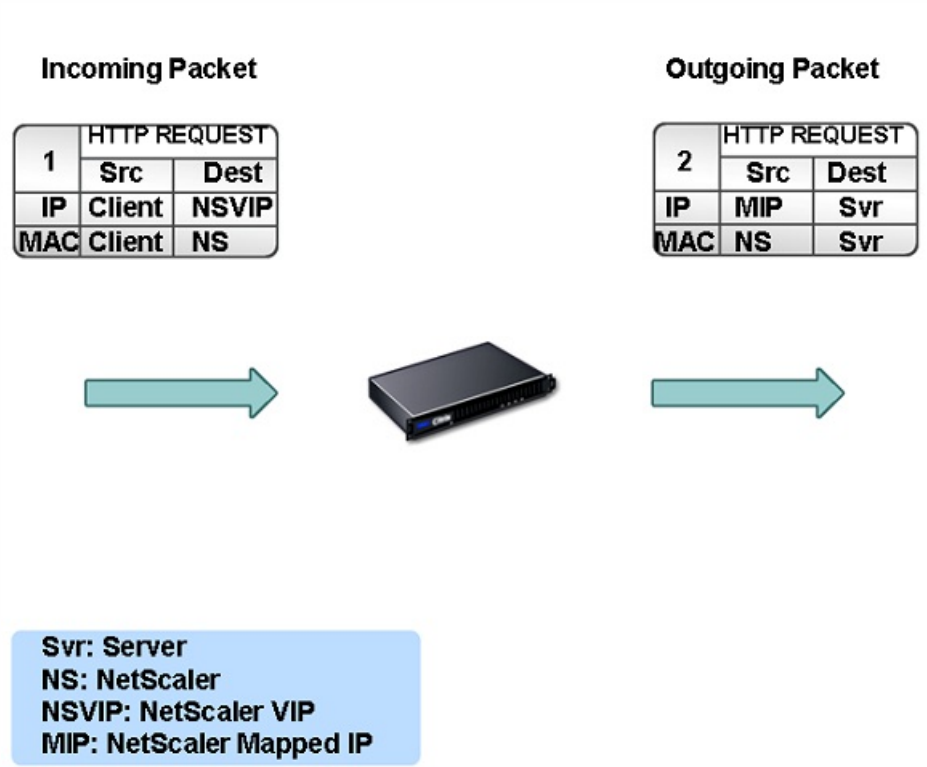
This section includes the following details:

- How the Destination IP Address Is Selected
- How the Source IP Address Is Selected

How the Destination IP Address Is Selected

Traffic sent to the NetScaler appliance can be sent to a virtual server or to a service. The appliance handles traffic to virtual servers and services differently. The NetScaler terminates traffic received at a virtual server IP (VIP) address and changes the destination IP address to the IP address of the server before forwarding the traffic to the server, as shown in the following diagram.

Figure 1. Proxying Connections to VIPs



Packets destined for a service are sent directly to the appropriate server, and the NetScaler does not modify the

destination IP addresses. In this case, the NetScaler functions as a proxy.

How the Source IP Address Is Selected

When the NetScaler appliance communicates with the physical servers or peer devices, by default, it does not use the IP address of the client. NetScaler maintains a pool of mapped IP addresses (MIPs) and subnet IP addresses (SNIPs), and selects an IP address from this pool to use as the source IP address of a connection to the physical server. Depending on the subnet in which the physical server is placed, NetScaler decides whether a MIP should be used or SNIP.

Note: If the Use Source IP (USIP) option is enabled, NetScaler uses the IP address of the client.

Enabling Use Source IP Mode

Dec 16, 2013

When the NetScaler appliance communicates with the physical servers or peer devices, by default, it uses one of its own IP addresses as the source IP. The appliance maintains a pool of mapped IP addresses (MIPs) and subnet IP addresses (SNIPs), and selects an IP address from this pool to use as the source IP address for a connection to the physical server. The decision of whether to select a MIP or a SNIP depends on the subnet in which the physical server resides.

If necessary, you can configure the NetScaler appliance to use the client's IP address as source IP. Some applications need the actual IP address of the client. The following use cases are a few examples:

- Client's IP address in the web access log is used for billing purposes or usage analysis.
- Client's IP address is used to determine the country of origin of the client or the originating ISP of the client. For example, many search engines such as Goggle provide content relevant to the location to which the user belongs.
- The application must know the client's IP address to verify that the request is from a trustworthy source.
- Sometimes, even though an application server does not need the client's IP address, a firewall placed between the application server and the NetScaler may need the client's IP address for filtering the traffic.

Enable Use Source IP mode (USIP) mode if you want NetScaler to use the client's IP address for communication with the servers. By default, USIP mode is disabled. USIP mode can be enabled globally on the NetScaler or on a specific service. If you enable it globally, USIP is enabled by default for all subsequently created services. If you enable USIP for a specific service, the client's IP address is used only for the traffic directed to that service.

As an alternative to USIP mode, you have the option of inserting the client's IP address (CIP) in the request header of the server-side connection for an application server that needs the client's IP address.

In earlier NetScaler releases, USIP mode had the following source-port options for server-side connections:

- Use the client's port. With this option, connections cannot be reused. For every request from the client, a new connection is made with the physical server.
- Use proxy port. With this option, connection reuse is possible for all requests from the same client. Before NetScaler release 8.1 this option imposed a limit of 64000 concurrent connections for all server-side connections.

In the later NetScaler releases , if USIP is enabled, the default is to use a proxy port for server-side connections and not reuse connections. Not reusing connections may not affect the speed of establishing connections.

By default, the Use Proxy Port option is enabled if the USIP mode is enabled.

For more information about the Use Proxy Port option, see "Using the Client Port When Connecting to the Server."

Note: If you enable the USIP mode, it is recommended to enable the Use Proxy Port option.
The following figure shows how the NetScaler uses IP addresses in USIP mode.

Figure 1. IP Addressing in USIP Mode

Recommended Usage

Enable USIP in the following situations:

- Load balancing of Intrusion Detection System (IDS) servers
- SMTP load balancing
- Stateless connection failover
- Sessionless load balancing
- If you use the Direct Server Return (DSR) mode

Note: When USIP is enabled, you must set server's gateway to one of the NetScaler owned IP addresses (either of type Subnet IP (SNIP) or mapped IP (MIP)) so that server's response always go through the NetScaler appliance. For more information about NetScaler owned IP addresses, see "Configuring NetScaler owned IP addresses."

- If you enable USIP, set the idle timeout for server connections to a value lower than the default value, so that idle connections are cleared quickly on the server side.
- For transparent cache redirection, if you enable USIP, enable L2CONN also.
- Because HTTP connections are not reused when USIP is enabled, a large number of server-side connections may accumulate. Idle server connections can block connections for other clients. Therefore, set limits on maximum number of connections to a service. Citrix also recommends setting the HTTP server time-out value, for a service on which USIP is enabled, to a value lower than the default, so that idle connections are cleared quickly on the server side.

To globally enable or disable USIP mode by using the command line interface

At the command prompt, type one of the following commands:

- enable ns mode USIP
- disable ns mode USIP

To enable USIP mode for a service by using the command line interface

At the command prompt, type:

set service <name>@ -usip (**YES** | **NO**)

Example

set service Service-HTTP-1 -usip YES

To globally enable or disable USIP mode by using the configuration utility

1. Navigate to System > Settings, in Modes and Features group, click Change modes.
2. Select or clear the Use Source IP option.

To enable USIP mode for a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open a service.
2. In Advanced Settings, select Traffic Settings, and select Use Source IP Address.

Configuring Network Address Translation

Jul 05, 2013

Network address translation (NAT) involves modification of the source and/or destination IP addresses and/or the TCP/UDP port numbers of IP packets that pass through the NetScaler appliance. Enabling NAT on the appliance enhances the security of your private network, and protects it from a public network such as the Internet, by modifying your networks source IP addresses when data passes through the NetScaler. Also, with the help of NAT entries, your entire private network can be represented by a few shared public IP addresses. The NetScaler supports the following types of network address translation:

- Inbound NAT (INAT), in which the NetScaler replaces the destination IP address in the packets generated by the client with the private IP address of the server.
- Reverse NAT (RNAT), in which the NetScaler replaces the source IP address in the packets generated by the servers with the public NAT IP addresses.

This document includes the following information:

Configuring INAT

Aug 28, 2013

When a client sends a packet to a NetScaler appliance that is configured for Inbound Network Address Translation (INAT), the appliance translates the packet's public destination IP address to a private destination IP address and forwards the packet to the server at that address.

The following configurations are supported:

- **IPv4-IPv4 Mapping**: A public IPv4 address on the NetScaler appliance listens to connection requests on behalf of a private IPv4 server. The NetScaler appliance translates the packet's public destination IP address to the destination IP address of the server and forwards the packet to the server at that address.
- **IPv4-IPv6 Mapping**: A public IPv4 address on the NetScaler appliance listens to connection requests on behalf of a private IPv6 server. The NetScaler appliance creates an IPv6 request packet with the IP address of the IPv6 server as the destination IP address.
- **IPv6-IPv4 Mapping**: A public IPv6 address on the NetScaler appliance listens to connection requests on behalf of a private IPv4 server. The NetScaler appliance creates an IPv4 request packet with the IP address of the IPv4 server as the destination IP address.
- **IPv6-IPv6 Mapping**: A public IPv6 address on the NetScaler appliance listens to connection requests on behalf of a private IPv6 server. The NetScaler appliance translates the packet's public destination IP address to the destination IP address of the server and forwards the packet to the server at that address.

When the appliance forwards a packet to a server, the source IP address assigned to the packet is determined as follows:

- If use subnet IP (USNIP) mode is enabled and use source IP (USIP) mode is disabled, the NetScaler uses a subnet IP address (SNIP) as the source IP address.
- If USNIP mode is disabled and USIP mode is disabled, the NetScaler uses a mapped IP address (MIP) as the source IP address.
- If USIP mode is enabled, and USNIP mode is disabled the NetScaler uses the client IP (CIP) address as the source IP address.
- If both USIP and USNIP modes are enabled, USIP mode takes precedence.
- You can also configure the NetScaler to use a unique IP address as the source IP address, by setting the proxyIP parameter.
- If none of the above modes are enabled and a unique IP address has not been specified, the NetScaler attempts to use a MIP as the source IP address.
- If both USIP and USNIP modes are enabled and a unique IP address has been specified, the order of precedence is as follows: USIP-unique IP-USNIP-MIP-Error.

To protect the NetScaler from DoS attacks, you can enable TCP proxy. However, if other protection mechanisms are used in your network, you may want to disable them.

You can create, modify, or remove an INAT entry.

To create an INAT entry by using the command line interface

At the command prompt, type the following commands to create an INAT entry and verify its configuration:

- add inat <name> <publicIP> <privateIP> [-tcpproxy (ENABLED | DISABLED)] [-ftp (ENABLED | DISABLED)] [-usip (ON | OFF)] [-usnip (ON | OFF)] [-proxyIP <ip_addr|ipv6_addr>]

- show inat [<name>]

Example

```
> add inat ip4-ip4 172.16.1.2 192.168.1.1 -proxyip 10.102.29.171
 Done
```

To modify an INAT entry by using the command line interface

To modify an INAT entry, type the set inat command, the name of the entry, and the parameters to be changed, with their new values.

To remove an INAT configuration by using the command line interface

At the command prompt, type:

rm inat <name>

Example

```
> rm inat ip4-ip4
 Done
```

To configure an INAT entry by using the configuration utility

Navigate to System > Network > Routes > INAT, and add a new INAT entry or edit an existing INAT entry.

To remove an INAT configuration by using the configuration utility

Navigate to System > Network > Routes > INAT, delete the INAT configuration.

Coexistence of INAT and Virtual Servers

Mar 20, 2012

If both INAT and RNAT are configured, the INAT rule takes precedence over the RNAT rule. If RNAT is configured with a network address translation IP (NAT IP) address, the NAT IP address is selected as the source IP address for that RNAT client.

The default public destination IP in an INAT configuration is the virtual IP (VIP) address of the NetScaler device. Virtual servers also use VIPs. When both INAT and a virtual server use the same IP address, the Vserver configuration overrides the INAT configuration.

Following are a few sample configuration setup scenarios and their effects.

Case	Result
You have configured a virtual server and a service to send all data packets received on a specific NetScaler port to the server directly. You have also configured INAT and enabled TCP. Configuring INAT in this manner sends all data packets received through a TCP engine before sending them to the server.	All packets received on the NetScaler, except those received on the specified port, pass through the TCP engine.
You have configured a virtual server and a service to send all data packets of service type TCP, that are received on a specific port on the NetScaler, to the server after passing through the TCP engine. You have also configured INAT and disabled TCP. Configuring INAT in this manner sends the data packets received directly to the server.	Only packets received on the specified port pass through the TCP engine.
You have configured a virtual server and a service to send all data packets received to either of two servers. You are attempting to configure INAT to send all data packets received to a different server.	The INAT configuration is not allowed.
You have configured INAT to send all received data packets directly to a server. You are attempting to configure a virtual server and a service to send all data packets received to two different servers.	The vserver configuration is not allowed.

Stateless NAT46 Translation

Aug 28, 2013

The stateless NAT46 feature enables communication between IPv4 and IPv6 networks through IPv4 to IPv6 packet translation, and vice versa, without maintaining any session information on the NetScaler appliance.

For a stateless NAT46 configuration, the appliance translates an IPv4 packet to IPv6 or an IPv6 packet to IPv4 as defined in RFCs 6145 and 2765.

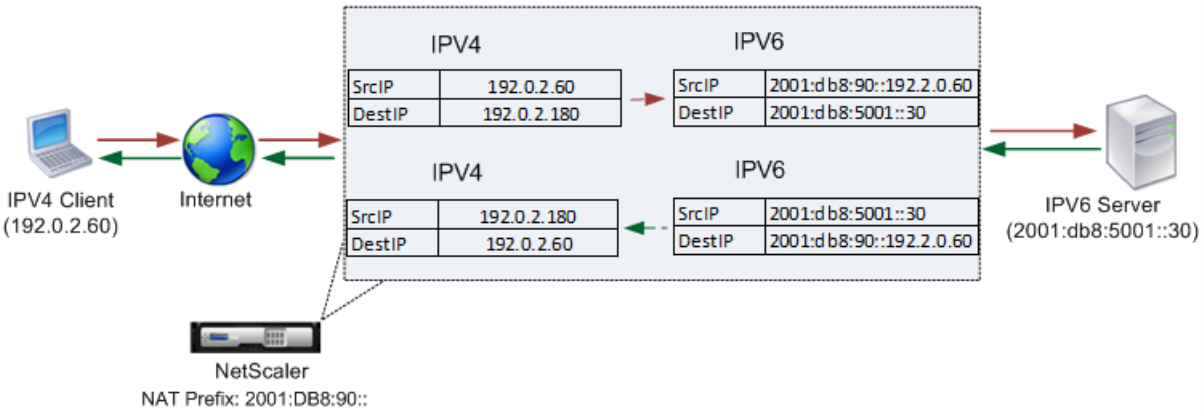
Note: This feature is supported only on NetScaler 10.e and later.

A stateless NAT46 configuration on the NetScaler appliance has the following components:

- **IPv4-IPv6 INAT entry**—An INAT entry defining a 1:1 relationship between an IPv4 address and an IPv6 address. In other words, an IPv4 address on the appliance listens to connection requests on behalf of an IPv6 server. An IPv4 request packet for this IPv4 address is translated into an IPv6 packet, and then the IPv6 packet is sent to the IPv6 server.
  The appliance translates an IPv6 response packet into an IPv4 response packet with its source IP address field set as the IPv4 address specified in the INAT entry. The translated packet is then sent to the client.

- **NAT46 IPv6 prefix**—A global IPv6 prefix of length 96 bits (128-32=96) configured on the appliance. During IPv4 packet to IPv6 packet translation, the appliance sets the source IP address of the translated IPv6 packet to a concatenation of the NAT46 IPv6 prefix [96 bits] and the IPv4 source address [32 bits] that was received in the request packet.
  During IPv6 packet to IPv4 packet translation, the appliance sets the destination IP address of the translated IPv4 packet to the last 32 bits of the destination IP address of the IPv6 packet.

Consider an example in which an enterprise hosts site www.example.com on server S1, which has an IPv6 address. To enable communication between IPv4 clients and IPv6 server S1, NetScaler appliance NS1 is deployed with a stateless NAT46 configuration that includes an IPv4-IPv6 INAT entry for server S1, and a NAT46 Prefix. The INAT entry includes an IPv4 address at which the appliance listens to connection requests from IPv4 clients on behalf of the IPv6 server S1.



The following table lists the settings used in this example:

Entities	Name	Value
IP address of the client	Client_IPv4 (for reference purposes only)	192.0.2.60
IPv6 address of the server	Sevr_IPv6 (for reference purposes only)	2001:DB8:5001::30
IPv4 address defined in the INAT entry for IPv6 server S1	Map-Sevr-IPv4 (for reference purposes only)	192.0.2.180

Entities	Name	Value
IPv6 prefix for NAT 46 translation	NAT46_Prefix (for reference purposes only)	2001:DB8:90::

Following is the traffic flow in this example:

1. IPv4 Client CL1 sends a request packet to the Map-Sevr-IPv4 (192.0.2.180) address on the NetScaler appliance.
2. The appliance receives the request packet and searches the NAT46 INAT entries for the IPv6 address mapped to the Map-sevr-IPv4 (192.0.2.180) address. It finds the Sevr-IPv6 (2001:DB8:5001::30) address.
3. The appliance creates a translated IPv6 request packet with:
   - Destination IP address field = Sevr-IPv6 = 2001:DB8:5001::30
   - Source IP address field = Concatenation of NAT Prefix (First 96 bits) and Client_IPv4 (last 32 bits) = 2001:DB8:90::192.0.2.60
4. The appliance sends the translated IPv6 request to Sevr-IPv6.
5. The IPv6 server S1 responds by sending an IPv6 packet to the NetScaler appliance with:
   - Destination IP address field = Concatenation of NAT Prefix (First 96 bits) and Client_IPv4 (last 32 bits)= 2001:DB8:90::192.0.2.60
   - Source IP address field = Sevr-IPv6 = 2001:DB8:5001::30
6. The appliance receives the IPv6 response packet and verifies that its destination IP address matches the NAT46 prefix configured on the appliance. Because the destination address matches the NAT46 prefix, the appliance searches the NAT46 INAT entries for the IPv4 address associated with the Sevr-IPv6 address (2001:DB8:5001::30). It finds the Map-Sevr-IPv4 address (192.0.2.180).
7. The appliance creates an IPv4 response packet with:
   - Destination IP address field = The NAT46 prefix stripped from the destination address of the IPv6 response = Client_IPv4 (192.0.2.60)
   - Source IP address field = Map-Sevr-IPv4 address (192.0.2.180)
8. The appliance sends the translated IPv4 response to client CL1.

Configuring Stateless NAT46

Updated: 2013-09-04

Creating the required entities for stateless NAT46 configuration on the NetScaler appliance involves the following procedures:

1. Create an IPv4-IPv6 mapping INAT entry with stateless mode enabled.
2. Add a NAT46 IPv6 prefix.

To configure an INAT mapping entry by using the command line interface

At the command prompt, type:

- add inat <name> <publicIPv4> <privateIPv6> -mode STATELESS
- show inat <name>

To add an NAT46 prefix by using the command line interface

At the command prompt, type:

- set inatparam -nat46v6Prefix <ipv6_addr|*>
- show inatparam

Example

```
> add inat exmpl-com-stls-nat46 192.0.2.180
```

2001:DB8:5001::30 -mode stateless
Done

> set inatparam -nat46v6Prefix 2001:DB8:90::/96
Done

To configure an INAT mapping entry by using the configuration utility

1. Navigate to System > Network > Routes > INAT.
2. Add a new INAT entry, or edit an existing INAT entry.
3. Set the following parameters:
   - Name*
   - Public IP Address*
   - Private IP Address* (Select the IPv6 check box and enter the address in IPv6 format.)
   - Mode (Select Stateless from the drop down list.)

   * A required parameter

To add a NAT46 prefix by using the configuration utility

Navigate to System > Network, in the Settings group, click Configure INAT Parameters, and set the Prefix parameter.

Setting Global Parameters for Stateless NAT46

The appliance provides some optional global parameters for stateless NAT46 configurations.

To set global parameters for stateless NAT46 by using the command line interface

At the command prompt, type:

- set inatparam [-nat46IgnoreTOS (YES | NO)] [-nat46ZeroCheckSum (ENABLED | DISABLED)] [-nat46v6Mtu <positive_integer>] [-nat46FragHeader (ENABLED | DISABLED)]
- show inatparam

Example

> set inatparam -nat46IgnoreTOS YES -nat46ZeroCheckSum DISABLED -nat46v6Mtu 1400 -nat46FragHeader DISABLED
Done

To set global parameters for stateless NAT46 by using the configuration utility

Navigate to System > Network, in the Settings group, click Configure INAT Parameters.

Limitations of Stateless NAT46

The following limitations apply to stateless NAT46:

- Translation of IPv4 options is not supported.
- Translation of IPv6 routing headers is not supported.
- Translation of hop-by-hop extension headers of IPv6 packets is not supported.
- Translation of ESP and EH headers of IPv4 packets is not supported.
- Translation of multicast packets is not supported.
- Translation of destination option headers and source routing headers is not supported.
- Translation of fragmented IPv4 UDP packets that do not contain UDP checksum is not supported.

DNS64

Feb 23, 2014

The NetScaler DNS64 feature responds with a synthesized DNS AAAA record to an IPv6 client sending an AAAA request for an IPv4-only domain. The DNS64 feature is used with the NAT64 feature to enable seamless communication between IPv6-only clients and IPv4-only servers. DNS64 enables discovery of the IPv4domain by the IPV6 only clients, and NAT64 enables communication between the clients and servers.

For synthesizing an AAAA record, the NetScaler appliance fetches a DNS A record from a DNS server. The DNS64 prefix is a 96-bit IPv6 prefix configured on the NetScaler appliance. The NetScaler appliance synthesizes the AAAA record by concatenation of the DNS64 Prefix (96 bits) and the IPv4 address (32 bits).

For enabling communication between IPv6 clients and IPv4 servers, a NetScaler appliance with DNS64 and NAT64 configuration can deployed either on the IPv6 client side or on the IPv4 server side. In both cases, the DNS64 configuration on the NetScaler appliance is similar and includes a load balancing virtual server acting as a proxy server for DNS servers. If the NetScaler appliance is deployed on the client side, the load balancing virtual server must be specified, on the IPv6 client, as the nameserver for a domain.

Consider an example where a NetScaler appliance with DNS64 and NAT64 configuration is configured on the IPv4 side. In this example, an enterprise hosts site www.example.com on server S1, which has an IPv4 address. To enable communication between IPv6 clients and IPv4 server S1, NetScaler appliance NS1 is deployed with a DNS64 and stateful NAT64 configuration.

The DNS64 configuration includes DNS load balancing virtual server LBVS-DNS64-1, on which the DNS64 option is enabled. A DNS64 policy named DNS64-Policy-1, and an associated DNS64 action named DNS64-Action-1, are also configured on NS1, andDNS64-Policy-1 is bound to LBVS-DNS64-1. LBVS-DNS64-1 acts as a DNS proxy server for DNS servers DNS-1 and DNS-2.

When traffic arriving at LBVS-DNS64-1 matches the conditions specified in DNS64-Policy-1, the traffic is processed according to the settings in DNS64-Action-1. DNS64-Action-1 specifies the DNS64 prefix used, with the A record received from a DNS server, to synthesize an AAAA record.

The global DNS parameter cacherecords is enabled on the NetScaler appliance, so the appliance caches DNS records. This setting is necessary for the DNS64 to work properly.

The following table lists the settings used in the above example:

Entity	Name	Value
IPv6 client	CL1 (for reference purposes only)	• IP address = 2001:DB8:5001::30
DNS64 Prefix		• 2001:DB8:300::
Service on NS representing DNS server DNS-1	SVC-DNS-1	• IP address = 203.0.113.50 • Port = 53
Service on NS representing DNS	SVC-DNS-2	• IP address = 203.0.113.60

server DNS-2		• Port = 53
DNS64 action	DNS64-Action-1	• DNS64 Prefix=2001:DB8:300::
DNS64 policy	DNS64-Policy-1	• DNS64 action = DNS64-Action-1 • Rule= CLIENT.IP.SRC.IN_SUBNET(2001:DB8:5001::/64)
DNS load balancing virtual server	LBVS-DNS64-1	• IP address=2001:DB8:9999::99 • Bound DNS services= SVC-DNS-1, SVC-DNS-2 • DNS64=Enabled • Bound DNS64 policy= DNS64-Policy-1

Following is the traffic flow in this example:

1. IPv6 client CL1 sends a DNS AAAA request for the IPv6 address of the site www.example.com.
2. The request is received by the DNS load balancing virtual server LBVS-DNS64-1 on NetScaler appliance NS1.
3. NS1 checks its DNS cache records for the requested AAAA record and finds that AAAA record for the site www.example.com does not exist in the DNS cache.
4. LBVS-DNS64-1's load balancing algorithm selects DNS server DNS-1 and forwards the AAAA request to it.
5. Because the site www.example.com is hosted on an IPv4 server, the DNS server DNS-1 does not have any AAAA record for the site www.example.com.
6. DNS-1 sends either an empty DNS AAAA response or an error message to LBVS-DNS64-1.
7. Because DNS64 option is enabled on LBVS-DNS64-1 and the AAAA request from CL1 matches the condition specified in DNS64-Policy-1, NS1 sends a DNS A request to DNS-1 for the IPv4 address of www.example.com.
8. DNS-1 responds by sending the DNS A record for www.example.com to LBVS-DNS64-1. The A record includes the IPv4 address for www.example.com.
9. NS1 synthesizes an AAAA record for the site www.example.com with:
   - IPv6 address for site www.example.com = Concatenation of DNS64 Prefix (96 bits) specified in the associated DNS64action, and IPv4 address of DNS A record (32 bits) = 2001:DB8:300::192.0.2.60
10. NS1 sends the synthesized AAAA record to IPv6 client CL1. NS1 also caches the A record into its memory. NS1 uses the cached A record to synthesize AAAA records for subsequent AAAA requests.

-

Points to Consider for a DNS64 Configuration

Before configuring DNS64 on a NetScaler appliance, consider the following points:

- The DNS64 feature of the NetScaler appliance is compliant with RFC 6174.
- The DNS64 feature of the NetScaler appliance does not support DNSSEC. The NetScaler appliance does not synthesize an AAAA record from a DNSSEC response received from a DNS server. A response is classified as a DNSSEC response, only if it contains RRSIG records.

- The NetScaler appliance supports DNS64 prefix of length of only 96 bits.
- Though the DNS64 feature is used with the NAT64 feature, the DNS64 and NAT64 configurations are independent on the NetScaler appliance. For a particular flow, you must specify the same IPv6 prefix value for the DNS64 prefix and the

NAT64 prefix parameters, so that the synthesized IPv6 addresses received by the client are routed to the particular NAT64 configuration. For more information on configuring NAT64 on a NetScaler appliance, see "Stateful NAT64."

- The following are the different cases of DN64 processing by the NetScaler appliance:
  - If the AAAA response from the DNS server includes AAAA records, then each record in the response is checked for the set of exclusion rule configured on the NetScaler appliance for the particular DNS64 configuration. The NetScaler removes the IPv6 addresses, whose prefix matches the exclusion rule, from the response. If the resulting response includes at least one IPv6 record, the NetScaler appliance forwards this response to the client, else, the appliance synthesizes a AAAA response from the A record of the domain and sends it to the IPv6 client.
  - If the AAAA response from the DNS server is an empty answer response, the appliance requests for A resource records with the same domain name or searches in its own records if the appliance is an authentic domain name server for the domain. If the request results in an empty answer or error, the same is forwarded to the client.
  - If the response from the DNS server includes RCODE=1 (format error), the NetScaler appliance forwards the same to the client. If there is no response before the timeout, the NetScaler appliance sends a response with RCODE=2 (server failure) to the client.
  - If the response from the DNS server includes a CNAME, the chain is followed until the terminating A or AAAA record is reached. If the CNAME does not have any AAAA resource records, the NetScaler appliance fetches the DNS A record to be used for synthesizing AAAA record. The CNAME chain is added to the answer section along with the synthesized AAAA record and then sent to the client.
- The DNS64 feature of the NetScaler appliance also supports responding to PTR request. When a PTR request for a domain of an IPv6 address is received on the appliance and the IPv6 address matches any of the configured DNS64 prefix, the appliance creates a CNAME record mapping the IP6-ARPA domain into the corresponding IN-ADDR.ARPA domain and the newly formed IN-ADDR.ARPA domain is used for resolution. The appliance searches the local PTR records and if the records are not present, the appliance sends a PTR request for IN-ADDR.ARPA domain to the DNS server. The NetScaler appliance uses the response from the DNS server to synthesize response for the initial PTR request.

Configuration Steps

Updated: 2013-09-30

Creating the required entities for stateful NAT64 configuration on the NetScaler appliance involves the following procedures:

- **Add DNS services.** DNS services are logical representation of DNS servers for which the NetScaler appliance acts as a DNS proxy server. For more information on setting optional parameters of a service, see "Load Balancing".
- **Add DNS64 action and DNS64 policy and then bind the DNS64 action to the DNS64 policy.** A DNS64 policy specifies conditions to be matched against traffic for DNS64 processing according to the settings in the associated DNS64 action. The DNS64 action specifies the mandatory DNS64 prefix and the optional exclude rule and mapped rule settings.
- **Create a DNS load balancing virtual server and bind the DNS services and the DNS64 policy to it.** The DNS load balancing virtual server acts as a DNS proxy server for DNS servers represented by the bound DNS services. Traffic arriving at the virtual server is matched against the bound DNS64 policy for DNS64 processing. For more information on setting optional parameters of a load balancing virtual server, see "Load Balancing".
  Note: The command line interface has separate commands for these two tasks, but the configuration utility combines them in a single dialog box.
- **Enable caching of DNS records.** Enable the global parameter for the NetScaler appliance to cache DNS records, which are obtained through DNS proxy operations. For more information on enabling caching of DNS records, see "Enabling Caching of DNS Records".

To create a service of type DNS by using the command line interface

At the command prompt, type:

- add service <name> <IP> <serviceType> <port> ...

To create a DNS64 action by using the command line interface

At the command prompt, type:

- add dns action64 <actionName> -Prefix <ipv6_addr|*> [-mappedRule <expression>] [-excludeRule <expression>]

To create a DNS64 policy by using the command line interface

At the command prompt, type:

- add dns policy64 <name> -rule <expression> -action <string>

To create a DNS load balancing virtual server by using the command line interface

At the command prompt, type:

- add lb vserver <name> DNS <IPAddress> <port> -dns64 (ENABLED | DISABLED) [-bypassAAAA (YES | NO)] ...

To bind the DNS services and the DNS64 policy to the DNS load balancing virtual server by using the command line interface

At the command prompt, type:

- bind lb vserver <name> <serviceName> ...
- bind lb vserver <name> -policyName <string> -priority <positive_integer> ...

Example

```
 > add service SVC-DNS-1 203.0.113.50 DNS 53
 Done

> add service SVC-DNS-2 203.0.113.60 DNS 53
 Done

> add dns Action64 DNS64-Action-1 -Prefix 2001:DB8:300::/96
 Done

> add dns Policy64 DNS64-Policy-1 -rule "CLIENT.IPv6.SRC.IN_SUBNET(2001:DB8:5001::/64)"
-action DNS64-Action-1
 Done

> add lb vserver LBVS-DNS64-1 DNS 2001:DB8:9999::99 53 -dns64 ENABLED
 Done

> bind lb vserver LBVS-DNS64-1 SVC-DNS-1
 Done

> bind lb vserver LBVS-DNS64-1 SVC-DNS-2
 Done

> bind lb vserver LBVS-DNS64-1 -policyname DNS64-Policy-1 -priority 2
 Done
```

To create a service of type DNS by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and add a new service.
2. Set the following parameters:
   - Service Name*
   - Server*
   - Protocol* (Select DNS from the drop down list.)
   - Port*

To create a DNS64 action by using the configuration utility

Navigate to Traffic Management > DNS > Actions, on the DNS Actions64 tab, add a new DNS64 action.

To create a DNS64 policy by using the configuration utility

Navigate to Traffic Management > DNS > Policies, on the DNS Policies64 tab, add a new DNS64 policy.

To create a DNS load balancing virtual server and bind the DNS services and the DNS64 policy to it by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and add a new virtual server.
2. Set the following parameters:
   - Name*
   - IP Address*
   - Protocol* (Select DNS from the drop down list.)
   - Port*
3. Select the Enable DNS64 option.
4. In the Services pane, bind the service to the virtual server.
5. In the Policies pane, bind the policy to the virtual server.

Stateful NAT64 Translation

May 11, 2012

The stateful NAT64 feature enables communication between IPv6 clients and IPv4 servers through IPv6 to IPv4 packet translation, and vice versa, while maintaining session information on the NetScaler appliance.

A stateful NAT64 configuration on the NetScaler appliance has the following components:

- **NAT64 rule**— An entry consisting of an ACL6 rule and a netprofile, which consists of a pool of NetScaler owned SNIP Addresses.
- **NAT64 IPv6 Prefix**— A global IPv6 prefix of length 96 bits (128-32=96) configured on the appliance.
  Note: Currently the NetScaler appliance supports only one prefix to be used commonly with all NAT 64 rules.

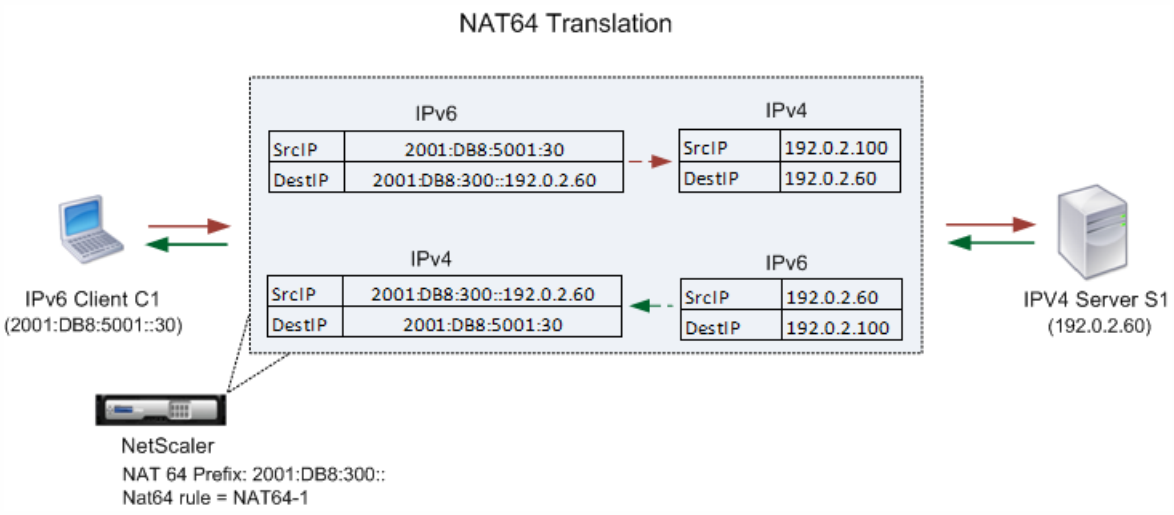
The NetScaler appliance considers an incoming IPv6 packet for NAT64 translation when all of the following conditions are met:

- The incoming IPv6 packet matches the ACL6 rule bound to a NAT64 rule.
- The destination IP address of the IPv6 packet matches the NAT64 IPv6 prefix.

When an IPv6 request packet received by the NetScaler appliance matches an ACL6 defined in a NAT64 rule and the destination IP of the packet matches the NAT64 IPv6 prefix, the NetScaler appliance considers the IPv6 packet for translation.

The appliance translates this IPv6 packet to an IPv4 packet with a source IP address matching one of the IP address bound to the netprofile defined in the NAT64 rule, and a destination IP address consisting of the last 32 bits of the destination IPv6 address of the IPv6 request packet. The NetScaler appliance creates a NAT64 session for this particular flow and forwards the packet to the IPv4 server. Subsequent responses from the IPv4 server and requests from the IPv6 client are translated accordingly by the appliance, on the basis of information in the particular NAT64 session.

Consider an example in which an enterprise hosts site www.example.com on server S1, which has an IPv4 address. To enable communication between IPv6 clients and IPv4 server S1, NetScaler appliance NS1 is deployed with a stateful NAT64 configuration that includes a NAT64 rule and a NAT64 prefix. A mapped IPv6 address of server S1 is formed by concatenating the NAT64 IPv6 prefix [96 bits] and the IPv4 source address [32 bits]. This mapped IPv6 address is then manually configured in the DNS servers. The IPv6 clients get the mapped IPv6 address from the DNS servers to communicate withIPv4 server S1.



The following table lists the settings used in this example:

Entities	Name	Value
IPv6 address of client CL1	Client_IPv6 (for reference purposes only)	2001:DB8:5001::30
IPv4 address of server S1	Sevr_IPv4 (for reference purposes only)	192.0.2.60
IPv6 prefix for NAT64 translation	NAT64_Prefix (for reference purposes only)	2001:DB8:300::
Mapped IPv6 address (NAT64_Prefix + Sevr_IPv4) of server S1 for IPv6 clients to reach server S1	Map-Sevr-IPv6 (for reference purposes only)	2001:DB8:300::192.0.2.60
ACL6 rule	ACL6-1	• Action = ALLOW • Source IP address =2001:DB8:5001::30
IPset	IPset-1	IP addresses bound (of type SNIPs) = 192.0.2.100 and 192.0.2.102
Netprofile	Netprofile-1	Source IP address = IPset-1
NAT64 rule	NAT64-1	ACL6 rule = ACL6-1 Netprofile = Netprofile-1

Following is the traffic flow in this example:

1. IPv6 client CL1 sends a request packet to Map-Sevr-IPv6 (2001:DB8:300::192.0.2.60) address.
2. The NetScaler appliance receives the request packet. If the request packet matches the ACL6 defined in the NAT64 rule, and the destination IP address of the packet matches the NAT64 IPv6 prefix, the NetScaler considers the IPv6 packet for translation.
3. The appliance creates a translated IPv4 request packet with:
   - Destination IP address field containing the NAT64 prefix stripped from the destination address of the IPv6 request (Sevr_IPv4 = 192.0.2.60)
   - Source IP address field containing one of the IPv4 address bound to Netprofile-1(in this case, 192.0.2.100)
4. The NetScaler appliance creates a NAT64 session for this flow and sends the translated IPv4 request to server S1.
5. IPv64 server S1 responds by sending an IPv4 packet to the NetScaler appliance with:
   - Destination IP address field containing 192.0.2.100
   - Source IP address field containing the address ofSevr_IPv4(192.0.2.60)
6. The appliance receives the IPv4 response packet, searches all the session entries, and finds that the IPv6 response packet matches the NAT64 session entry created in step 4. The appliance considers the IPv4 packet for translation.
7. The appliance creates a translated IPv6 response packet with:

- Destination IP address field=Client_IPv6=2001:DB8:5001::30
- Source IP address field = Concatenation of NAT64 Prefix (First 96 bits) and Sevr_IPv4 (last 32 bits) =2001:DB8:300::192.0.2.60

8. The appliance sends the translated IPv6 response to client CL1.

-

Limitations of Statelful NAT64

The following limitations apply to stateful NAT64 translation:

- Translation of IPv4 options is not supported.
- Translation of IPv6 routing headers is not supported.
- Translation of hop-by-hop extension headers of IPv6 packets is not supported.
- Translation of ESP and EH headers of IPv6 packets is not supported.
- Translation of multicast packets is not supported.
- Packets of Stream Control Transmission Protocol (SCTP), Datagram Congestion Control Protocol (DCCP), and IPSec, are not translated.

Configuring Stateful NAT64

Updated: 2013-10-31

Creating the required entities for stateful NAT64 configuration on the NetScaler appliance involves the following procedures:

1. Add an ACL6 rule with action ALLOW.
2. Add an ipset, which binds multiple IP addresses.
3. Add a netprofile and bind the ipset to it. If you want to bind only one IP address, you need not create an ipset entity. In that case, bind the IP address directly to the netprofile.
4. Add a NAT64 rule, which includes binding the ACl6 rule and the netprofile to the NAT 64 rule.
5. Add a NAT64 IPv6 prefix.

To add an ACL6 rule by using the command line interface

At the command prompt, type:

- add ns acl6 <acl6name> <acl6action> ...

To add an IPset and bind multiple IPs to it by using the command line interface

At the command prompt, type:

- add ipset <name>
- bind ipset <name> <IPaddress ...>

To add a netprofile by using the command line interface

At the command prompt, type:

- add netprofile <name> -srcIP <IPaddress or IPset>

To add a NAT64 rule by using the command line interface

At the command prompt, type:

- add nat64 <name> <acl6name> -netProfile <string>

To add a NAT64 prefix by using the command line interface

At the command prompt, type:

- set ipv6 -natprefix <ipv6_addr|*>

Example

```
 > add acl6 ACL6-1 ALLOW -srcIPv6 2001:DB8:5001::30
 Done

> apply acls6
 Done

> add ip 192.0.2.100 255.255.255.0 –type SNIP
 Done

> add ip 192.0.2.102 255.255.255.0  –type SNIP
 Done

> add ipset IPset-1
 Done

> bind ipset IPset-1 192.0.2.100 192.0.2.102
IPAddress "192.0.2.100" bound
IPAddress "192.0.2.102" bound
 Done

> add netprofile Netprofile-1 -srcIP IPset-1
 Done

> add nat64 NAT64-1 ACL6-1 -netprofile Netprofile-1
 Done

> set ipv6 -natprefix 2001:DB8:300::/96
 Done
```

To add a NAT64 rule by using the configuration utility

Navigate to System > Network > Routes > NAT64, and a new NAT64 rule, or edit an existing rule.

To add a NAT64 prefix by using the configuration utility

Navigate to System > Network, in the Settings group, click Configure INAT Parameters, and set the Prefix parameter.

Configuring RNAT

Mar 15, 2017

In Reverse Network Address Translation (RNAT), the NetScaler appliance replaces the source IP addresses in the packets generated by the servers with public NAT IP addresses. By default, the appliance uses a Mapped IP address (MIP) as the NAT IP address. You can also configure the appliance to use a unique NAT IP address for each subnet. You can also configure RNAT by using Access Control Lists (ACLs). Use Source IP (USIP), Use Subnet IP (USNIP), and Link Load Balancing (LLB) modes affect the operation of RNAT. You can display statistics to monitor RNAT.

Note: The ephemeral port range for RNAT on the NetScaler appliance is 1024-65535.

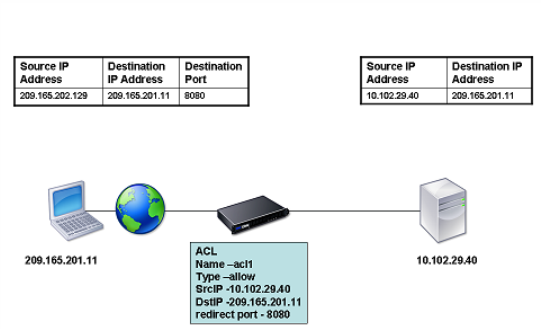
Note: The NetScaler appliance treats any received TCP packets destined to port 21 as FTP packets even if they belong to a protocol other than FTP. For example, connection fails for SFTP packets destined to port 21.

You can use either a network address or an extended ACL as the condition for an RNAT entry:

- **Using a Network address.** When you use a network address, RNAT processing is performed on all of the packets coming from the specified network.
- **Using Extended ACLs.** When you use ACLs, RNAT processing is performed on all packets that match the ACLs. To configure the NetScaler appliance to use a unique IP address for traffic that matches an ACL, you must perform the following three tasks:
  1. Configure the ACL.
  2. Configure RNAT to change the source IP address and Destination Port.
  3. Apply the ACL.

  The following diagram illustrates RNAT configured with an ACL.

  Figure 1. RNAT with an ACL

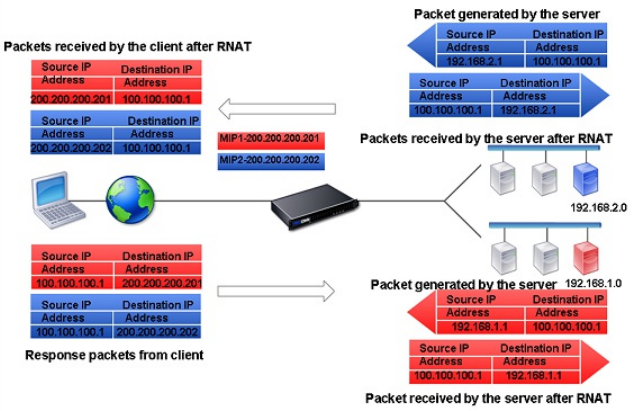


You have the following basic choices for the type of NAT IP address:

- **Using a MIP or SNIP as the NAT IP Address.** When using a MIP as the NAT IP address, the NetScaler appliance replaces the source IP addresses of server-generated packets with the a MIP. Therefore, the MIP address must be a public IP address. If Use Subnet IP (USNIP) mode is enabled, the NetScaler can use a subnet IP address (SNIP) as the NAT IP address.
- **Using a Unique IP Address as the NAT IP Address.** When using a unique IP address as the NAT IP address, the NetScaler appliance replaces the source IP addresses of server-generated packets with the unique IP address specified. The unique IP address must be a public NetScaler-owned IP address. If multiple NAT IP addresses are configured for a subnet, NAT IP selection uses the round robin algorithm.

  This configuration is illustrated in the following diagram.

  Figure 2. Using a Unique IP Address as the NAT IP Address



This section includes the following details:

- Creating an RNAT Entry
- Monitoring RNAT
- RNAT in USIP, USNIP, and LLB Modes
- Configuring RNAT for IPv6 Traffic

Creating an RNAT Entry

Updated: 2013-08-28

The following instructions provide separate command-line procedures for creating RNAT entries that use different conditions and different types of NAT IP addresses. In the configuration utility, all of the variations can be configured in the same dialog box, so there is only one procedure for configuration utility users.

To create an RNAT entry by using the command line interface

At the command prompt, type one the following commands to create, respectively, an RNAT entry that uses a network address as the condition and a MIP or SNIP as the NAT IP address, an RNAT entry that uses a network address as the condition and a unique IP address as the NAT IP address, an RNAT entry that uses an ACL as the condition and a MIP or SNIP as the NAT IP address, or an RNAT entry that uses an ACL as a condition and a unique IP address as the NAT IP address:

- **set rnat** <IPAddress> <netmask>
- **set rnat IPAddress** <netMask> -**natip** <NATIPAddress>
- **set rnat** <aclname> [-**redirectPort** <port>]
- **set rnat** <aclname> [-**redirectPort** <port>] -**natIP** <NATIPAddress>

Use the following command to verify the configuration:

- **show rnat**

Examples

A network address as the condition and a MIP or SNIP as the NAT IP address:

```
> set rnat 192.168.1.0 255.255.255.0
 Done
```

A network address as the condition and a unique IP address as the NAT IP address:

```
> set rnat 192.168.1.0 255.255.255.0 -natip 10.102.29.50
 Done
```

If instead of a single NAT IP address you specify a range, RNAT entries are created with all the NetScaler-owned IP addresses, except the NSIP, that fall within the range specified:

```
> set rnat 192.168.1.0 255.255.255.0  -natIP 10.102.29.[50-110]
 Done
```

An ACL as the condition and a MIP or SNIP as the NAT IP address:

```
> set rnat acl1
 Done
```

An ACL as a condition and a unique IP address as the NAT IP address:

```
> set rnat acl1  -natIP 209.165.202.129
Done
```

If instead of a single NAT IP address you specify a range, RNAT entries are created with all the NetScaler-owned IP addresses, except the NSIP, that fall within the range specified:

```
> set rnat acl1  -natIP 10.102.29.[50-70]
 Done
```

To create an RNAT entry by using the NetScaler GUI

1. Navigate to **System** > **Network** > **Routes** > **RNAT**.
2. In the **Action list**, select **Configure RNAT**.

Monitoring RNAT

Updated: 2013-09-27

You can display RNAT statistics to troubleshoot issues related to IP address translation.

To view RNAT statistics by using the command line interface

At the command prompt, type:

stat rnat
Example

```
> stat rnat

RNAT summary
                        Rate (/s)          Total
Bytes Received                0                0
Bytes Sent                    0                0
Packets Received              0                0
Packets Sent                  0                0
Syn Sent                      0                0
Current RNAT sessions         --               0
 Done
>
```

The following tables describes the statistics associated with RNAT and RNAT IP.

Table 1. RNAT Statistics

Statistic	Description
Bytes received	Bytes received during RNAT sessions
Bytes sent	Bytes sent during RNAT sessions
Packets received	Packets received during RNAT sessions
Packets sent	Packets sent during RNAT sessions
Syn sent	Requests for connections sent during RNAT sessions
Current sessions	Currently active RNAT sessions

To monitor RNAT by using the NetScaler GUI

Navigate to **System** > **Network** > **Routes** > RNAT, and click Statistics.

RNAT in USIP, USNIP, and LLB Modes

Updated: 2013-12-18

Before configuring a RNAT rule, consider the following points:

- When RNAT and Use Source IP (USIP) are both configured on the NetScaler appliance, RNAT takes precedence. In other words, the source IP address of the packets, which matches a RNAT rule, is replaced according to the setting in the RNAT rule.
- When RNAT and Use SNIP (USNIP) are configured on the NetScaler appliance, selection of the source IP address is based on the state of USNIP, as follows:
  - If USNIP is off, the NetScaler appliance uses the mapped IP addresses.
  - If USNIP is on, the NetScaler uses a SNIP address as the NAT IP address.

This behavior does not apply when a unique NAT IP address is used.

In a topology where the NetScaler appliance performs both Link Load Balancing (LLB) and RNAT for traffic originating from the server, the appliance selects the source IP address based on the router. The LLB configuration determines selection of the router. For more information about LLB, see "Link Load Balancing."

Configuring RNAT for IPv6 Traffic

Reverse Network Address Translation (RNAT) rules for IPv6 packets are called RNAT6s. When an IPv6 packet generated by a server matches the conditions specified in the RNAT6 rule, the appliance replaces the source IPv6 address of the IPv6 packet with a configured NAT IPv6 address before forwarding it to the destination. The NAT IPv6 address is one of the NetScaler owned SNIP6 or VIP6 addresses.

When configuring an RNAT6 rule, you can specify either an IPv6 prefix or an ACL6 as the condition:

- **Using a IPv6 network address**. When you use an IPv6 prefix, the appliance performs RNAT processing on those IPv6 packets whose IPv6 address matches the prefix.
- **Using ACL6s**. When you use an ACL6, the appliance performs RNAT processing on those IPv6 packets that match the conditions specified in the ACL6.

You have one of the following options to set the NAT IP address:

- Specify a set of NetScaler owned SNIP6 and VIP6 addresses for an RNAT6 rule. The NetScaler appliance uses any one of the IPv6 addresses from this set as a NAT IP address for each session. The selection is based on the round robin algorithm and is done for each session.
- Do not specify any NetScaler owned SNIP6 or VIP6 address for an RNAT6 rule. The NetScaler appliance uses any one of the NetScaler owned SNIP6 or VIP6 addresses as a NAT IP address. The selection is based on the next hop network to which an IPv6 packet that matches the RNAT rule is destined.

To create an RNAT6 rule by using the command line interface

At the command prompt, to create the rule and verify the configuration, type:

- **add rnat6** <name> (<network> | (<acl6name> [-**redirectPort** <port>]))
- **bind rnat6** <name> <natIP6>@ ...

- **show rnat6**

To modify or remove an RNAT6 rule by using the command line interface

- To modify an RNAT6 rule whose condition is an ACL6, type the **set rnat6** <name> command, followed by a new value for the redirectPort parameter.
- To remove an RNAT6 rule, type the **clear rnat6** <name> command.
- **show rnat6**

To configure an RNAT6 rule by using the NetScaler GUI

Navigate to **System** > **Network** > **Routes** > **RNAT6**, and add a new RNAT6 rule, or edit an existing rule.

Logging Start Time and Connection Closure Reasons in RNAT Log Entries

For diagnosing or troubleshooting problems related to RNAT, the NetScaler appliance logs RNAT sessions whenever they are closed.

A log message for an RNAT session consists of the following information:

- NetScaler owned IP address (NSIP address or SNIP address) from which the log message is sourced
- Time stamp of log creation
- Protocol of the RNAT session
- Source IP address
- RNAT IP address
- Destination IP address
- Start time of the RNAT session
- Closing time of the RNAT session
- Total bytes sent by the NetScaler appliance for this RNAT session
- Total bytes received by the NetScaler appliance for this RNAT session
- Reason for closure of the RNAT session. The NetScaler appliance logs closure reason for TCP RNAT sessions that do not use the TCP proxy (TCP proxy disabled) of the appliance. The following are the type of closure reasons that are logged for TCP RNAT sessions:
  - TCP FIN. The RNAT session was closed because of a TCP FIN sent by either the source or destination device.
  - TCP RST. The RNAT session was closed because of a TCP Reset that was sent by either the source or destination device.
  - TIMEOUT. The RNAT session timed out.

The following table shows some sample log entries for RNAT sessions.

Type of Entry	Sample Log Entry
Sample log entry for UDP RNAT session	Dec 1 15:28:12 <local0.info> 10.102.53.114 12/01/2015:15:28:12 GMT 0-PPE-0 : default **UDP** NAT_OTHERCONN_DELINK 154 0 : Source 1.2.2.5:23431 - Destination 192.168.123.122:22 - NatIP 192.168.123.1:4045 - Destination 192.168.123.122:22 - **Start Time 12/01/2015:15:26:58 GMT** - Delink Time 12/01/2015:15:28:12 GMT - Total_bytes_send 2511 - Total_bytes_recv 3725
Sample log entry for TCP RNAT session. The log entry shows that the session closed because of TCP Reset	Dec 1 15:29:59 <local0.info> 10.102.53.114 12/01/2015:15:27:59 GMT 0-PPE-0 : default TCP NAT_OTHERCONN_DELINK 152 0 : Source 1.2.2.5:33826 - Destination 192.168.123.122:22 - NatIP 192.168.123.1:2384 - Destination 192.168.123.122:22 - **Start Time 12/01/2015:15:27:40 GMT** - Delink Time 12/01/2015:15:27:59 GMT - Total_bytes_send 2147 - Total_bytes_recv 3257 - **Closure Reason TCP RST**
Sample log entry for TCP RNAT session. The log entry shows that the session timed out	Dec 1 15:30:12 <local0.info> 10.102.53.114 12/01/2015:15:30:12 GMT 0-PPE-0 : default TCP NAT_OTHERCONN_DELINK 155 0 : Source 1.2.2.5:64976 - Destination 192.168.123.115:22 - NatIP 192.168.123.1:19636 - Destination 192.168.123.115:22 - **Start Time 12/01/2015:15:27:25 GMT** - Delink Time 12/01/2015:15:30:12 GMT - Total_bytes_send 0 - Total_bytes_recv 0 - **Closure Reason TIMEOUT**

Stateful Connection Failover for RNAT

Connection failover helps prevent disruption of access to applications deployed in a distributed environment. The NetScaler appliance now supports stateful connection failover for connections related to RNAT rules in a NetScaler High Availability (HA) setup. In an HA setup, connection failover (or connection mirroring) refers to the process of keeping an established TCP or UDP connection active when a failover occurs.

The primary appliance sends messages to the secondary appliance to synchronize current information about the RNAT connections. The secondary appliance uses this connection information only in the event of a failover. When a failover occurs, the new primary NetScaler appliance has information about the connections established before the failover and hence continues to serve those connections even after the failover. From the client's perspective this failover is transparent. During the transition period, the client and server may experience a brief disruption and retransmissions.

Connection failover can be enabled per RNAT rule. For enabling connection failover on an RNAT rule, you enable the connFailover (Connection Failover) parameter of that specific RNAT rule by using either NetScaler command line or configuration utility.

To enable connection failover for a RNAT rule by using the command line interface

At the command prompt, type:

- **set rnat** <name> **-connfailover** (**ENABLED** | **DISABLED**)
- **show rnat**

To enable connection failover for a RNAT rule by using the NetScaler GUI

Navigate to **System** > **Network** > **Routes** > **RNAT**, and select **Connection Failover** while adding a new RNAT rule, or while editing an existing rule.

Code COPY

Configuring Prefix-Based IPv6-IPv4 Translation

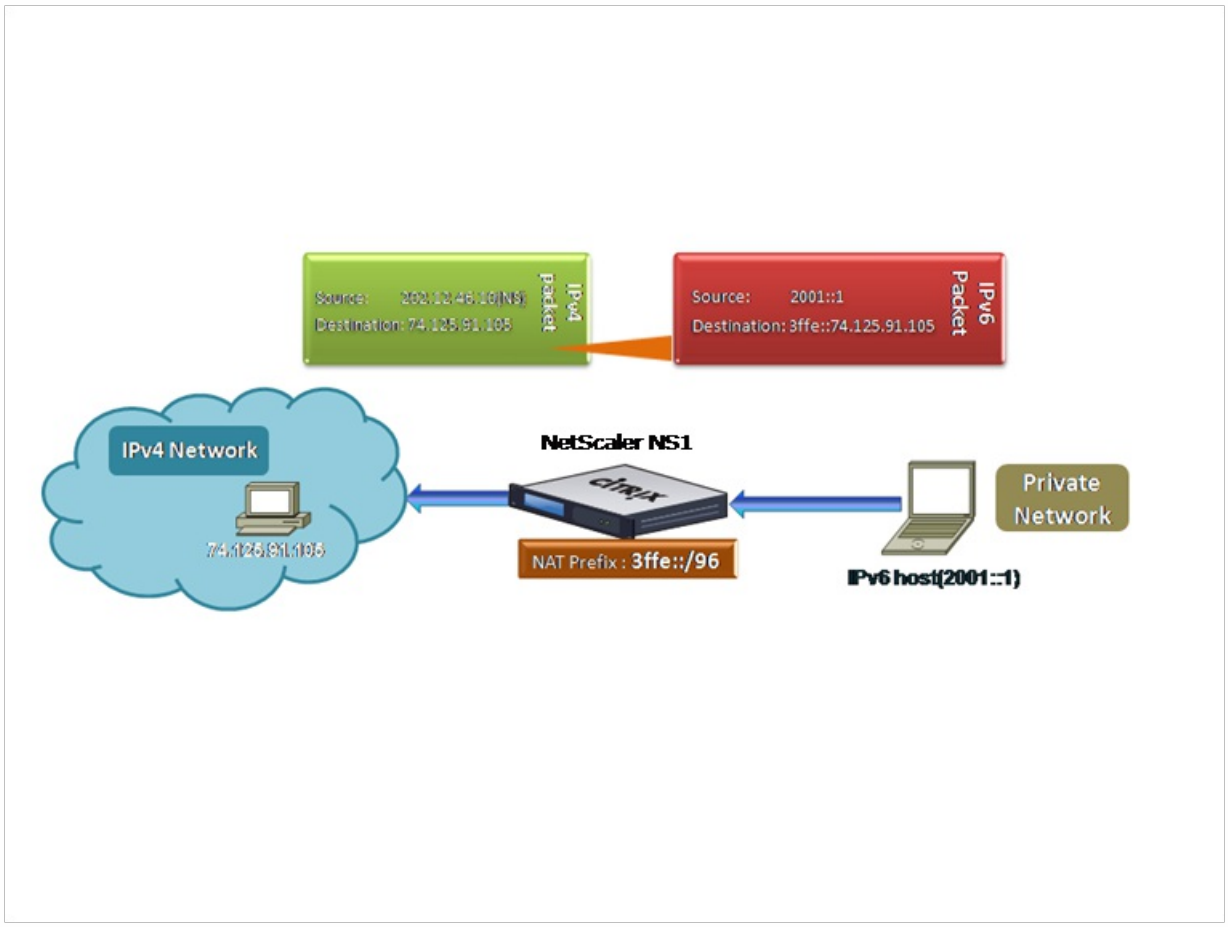
Aug 28, 2013

Prefix-based translation is a process of translating packets sent from private IPv6 servers into IPv4 packets, using an IPv6 prefix configured in the NetScaler appliance. This prefix has a length of 96 bits (128-32=96). The IPv6 servers embed the destination IP address of the IPv4 servers or hosts in the last 32 bits of the destination IP address field of the IPv6 packets. The first 96 bits of the destination IP address field are set as the IPv6 NAT prefix.

The NetScaler appliance compares the first 96 bits of the destination IP address of all the incoming IPv6 packets to the configured prefix. If there is a match, the NetScaler appliance generates an IPv4 packet and sets the destination IP address as the last 32 bits of the destination IP address of the matched IPv6 packet. IPv6 packets addressed to this prefix have to be routed to the NetScaler so that the IPv6-IPv4 translation is done by the NetScaler.

In the following diagram, 3ffe::/96 is configured as the IPv6 NAT prefix on NetScaler NS1. The IPv6 host sends an IPv6 packet with destination IP address 3ffe::74.125.91.105. NS1 compares the first 96 bits of the destination IP address of all the incoming IPv6 packets to the configured prefix, and they match. NS1 then generates an IPv4 packet and sets the destination IP address as 74.125.91.105.

Figure 1. IPv6-IPv4 Prefix-Based Translation



To configure prefix-based IPv6-IPv4 translation by using the command line interface

At the command prompt, type the following commands to set a NAT prefix and verify its configuration:

- set ipv6 [-natprefix <ipv6_addr|*>]
- show ipv6

Example

```
> set ipv6 -natprefix 3ffe::/96
 Done
```

To configure prefix-based IPv6-IPv4 translation by using the configuration utility

Navigate to System > Network, in the Settings group, click Configure INAT Parameters, and set the Prefix parameter.

IP Prefix NAT

Jan 04, 2016

The NetScaler appliance supports translating a part of the source IP address instead of the complete address of packets received on the appliance. IP prefix NAT includes changing one or more octets or bits of the source IP address.

The NetScaler appliance supports IP prefix NAT for traffic related to virtual servers and services for which the NetScaler does not maintain any session information. For example, virtual servers and services of type ANY, UDP, and DNS.

Use Case: Zonification of Clients for a Deployment of a NetScaler appliance and an Optimization Device

IP prefix NAT is very useful in a deployment that includes a NetScaler appliance and an optimization device (for example, Citrix ByteMobile). This type of deployment has different geographically located client networks, which share the same network address. The NetScaler appliance must send the traffic received from each of the client networks to the optimization device before forwarding to the destination.

The device sends the optimized traffic back to the NetScaler appliance. Because the optimization requirement is different for traffic from each client network, the optimization device must recognize the client network of each packet that it receives. The solution is to segregate traffic from each client network into a different zone by using VLANs. IP prefix NAT with a different setting is configured for each zone. The NetScaler appliance translates the last octet of the source IP address of every packet, and the translated octet value is different for each zone.

Consider an example of two zones, Z1 and Z2, sharing network address 192.0.2.0/24. On the NetScaler appliance, IP prefix NAT entities named natrule-1 and natrule-2 are configured for these two zones. Before the appliance forwards a packet from Z1, natrule-1 translates the last octet of the packet's source IP address to 100. Similarly, for packets from Z2, natrule-2 translates the last octet of the source IP address to 200. For two clients, CL1-Z1 in zone Z1 and CL1-Z2 in zone Z2, each with IP address 192.0.2.30, the NetScaler appliance translates the source IP address of CL1-Z1's packets to 100.0.2.30 and of CL1-Z2's packets to 200.0.2.30. The optimization device to which the NetScaler appliance sends the translated packets is configured to use a packet's source IP address to recognize the zone, so it applies the appropriate optimization configured for the zone from which the packet originated.

Configuration Steps

Configuring IP prefix NAT consists of the following steps:

Create a net profile and set the NAT Rule parameter of a net profile. A NAT rule specifies two IP addresses and a net mask. The first IP address (specified by IP Address parameter) is the source IP address that is to be translated with the second one (specified by IP Rewrite parameter). The net mask specifies the part of the source IP address that is to be translated with the same part of the second IP address.

Bind the net profile to load balancing virtual servers or services. A net profile with NAT rule setting can be bound to a virtual server or service of only type ANY, UDP, or DNS. After binding a net profile to a virtual server or service, the NetScaler appliance matches the source IP address of the incoming packets related to the virtual server or service with the NAT rule setting. The NetScaler then performs IP prefix NAT for packets that match the NAT rule.

To configure IP prefix NAT translation by using the command line

At the command prompt, type:

- **bind netProfile** <name> (-**natRule** <ip_addr> <netmask> <rewriteIp>)
- **show netprofile** <name>

In the following sample configuration, net profile PARTIAL-NAT-1 has IP prefix NAT settings and is bound to load balancing virtual server LBVS-1, which is of type ANY. For packets received on LBVS-1 from 192.0.0.0/8, the NetScaler appliance translates the last octet of the packet's source IP address to 100. For example, a packet with source IP address 192.0.2.30 received on LBVS-1, the NetScaler appliance translates the source IP address to 100.0.2.30 before sending it one of the bound servers.

```
> add netprofile PARTIAL-NAT-1

Done

> bind netprofile PARTIAL-NAT-1 –natrule 192.0.0.0 255.0.0.0 100.0.0.0

Done

> add lb vserver LBVS-1 ANY 203.0.113. 61 * -netprofile PARTIAL-NAT-1
```

Done

To configure IP prefix NAT by using the configuration utility

1. Navigate to **System** > **Network** > **Net Profiles**.

2. Set the following parameters under NAT Rules while adding or modifying NetProfiles.

- IP Address
- Netmask
- Rewrite IP

Configuring Static ARP

Aug 28, 2013

You can add static ARP entries to and remove static ARP entries from the ARP table. After adding an entry, you should verify the configuration. If the IP address, port, or MAC address changes after you create a static ARP entry, you must remove or manually adjust the static entry. Therefore, creating static ARP entries is not recommended unless necessary.

To add a static ARP entry by using the command line interface

At the command prompt, type:

- add arp -IPAddress <ip_addr> -mac<mac_addr> -ifnum <interface_name>
- show arp <IPAddress>

Example

```
> add arp -ip 10.102.29.6 -mac 00:24:e8:73:ca:ec -ifnum 1/1
 Done
```

To remove a static ARP entry by using the command line interface

At the command prompt, type the rm arp command and the IP address.

To add a static ARP entry by using the configuration utility

Navigate to System > Network > ARP Table, and a new ARP entry.

Specifying a VLAN in a Static ARP Entry

In a static ARP entry, you can specify the VLAN through which the destination device is accessible. This feature is useful when the interface specified in the static ARP entry is part of multiple tagged VLANs and the destination is accessible through one of the VLANs. The NetScaler appliance includes the specified VLAN ID in the outgoing packets matching the static ARP entry. If you don't specify a VLAN ID in an ARP entry, and the specified interface is part of multiple tagged VLANs, the appliance assigns the interface's native VLAN to the ARP entry.

For example, say NetScaler interface 1/2 is part of native VLAN 2 and of tagged VLANs 3 and 4, and you add a static ARP entry for network device A, which is part of VLAN 3 and is accessible through interface 1/2. You must specify VLAN 3 in the ARP entry for network device A. The NetScaler appliance then includes tagged VLAN 3 in all the packets destined to network device A, and sends them from interface 1/2.

If you don't specify a VLAN ID, the NetScaler appliance assigns native VLAN 2 for the ARP entry. Packets destined to device A are dropped in the network path, because they do not specify tagged VLAN 3, which is the VLAN for device A.

To specify a VLAN in a Static ARP entry by using the command line interface

At the command prompt, type:

1. **add arp -IPAddress** <ip_addr> **-mac**<mac_addr> **-ifnum** <interface_name> [-**vlan** <positive_integer>]
2. **show arp** <IPAddress>

Example

```
> add arp -ip 198.51.100.91 -mac 36:db:4b:f6:12:15 -ifnum 1/2 -vlan 3
Done
```

Setting the Timeout for Dynamic ARP Entries

Aug 28, 2013

You can globally set an aging time (time-out value) for dynamically learned ARP entries. The new value applies only to ARP entries that are dynamically learned after the new value is set. Previously existing ARP entries expire after the previously configured aging time.

You can specify an ARP time-out value of from 1 through 1200 seconds.

To set the time-out for dynamic ARP entries by using the command line interface

At the command prompt, type the following commands to set the time-out for dynamic ARP entries and verify its configuration:

- set arpparam -timeout <positive_integer>]
- show arpparam

Example

```
> set arpparam -timeout 500
 Done
```

To set the time-out for dynamic ARP entries to its default value by using the command line interface

At the command prompt, type the following commands to set the time-out for dynamic ARP entries to its default value and verify its configuration:

- unset arpparam
- show arpparam

Example

```
> unset arpparam
 Done
```

To set the time-out for dynamic ARP entries by using the configuration utility

Navigate to System > Network, in the Settings group, click Configure ARP Global Parameters, and set the ARP Table Entry Timeout parameter.

Configuring Neighbor Discovery

May 10, 2012

Neighbor discovery (ND) is one of the most important protocols of IPv6. It is a message-based protocol that combines the functionality of the Address Resolution Protocol (ARP), Internet Control Message Protocol (ICMP), and Router Discovery. ND allows nodes to advertise their link layer addresses and obtain the MAC addresses or link layer addresses of the neighboring nodes. This process is performed by the Neighbor Discovery protocol (ND6).

Neighbor discovery can perform the following functions:

Router Discovery

Enables a host to discover the local routers on an attached link and automatically configure a default router.

Prefix Discovery

Enables the host to discover the network prefixes for local destinations.
Note: Currently, the NetScaler does not support Prefix Discovery.

Parameter Discovery

Enables a host to discover additional operating parameters, such as MTU and the default hop limit for outbound traffic.

Address Autoconfiguration

Enables hosts to automatically configure IP addresses for interfaces both with and without stateful address configuration services such as DHCPv6. The NetScaler does not support Address Autoconfiguration for Global IPv6 addresses.

Address Resolution

Equivalent to ARP in IPv4, enables a node to resolve a neighboring node's IPv6 address to its link-layer address.

Neighbor Unreachability Detection

Enables a node to determine the reachability state of a neighbor.

Duplicate Address Detection

Enables a node to determine whether an NSIP address is already in use by a neighboring node.

Redirect

Equivalent to the IPv4 ICMP Redirect message, enables a router to redirect the host to a better first-hop IPv6 address to reach a destination.

Note: The NetScaler does not support IPv6 Redirect.
To enable neighbor discovery, you create entries for the neighbors.

This section includes the following details:

- Adding IPv6 Neighbors
- Removing IPv6 Neighbors

Adding IPv6 Neighbors

Updated: 2013-08-28

Adding IPv6 neighbors enables neighbor discovery.

To add an IPv6 neighbor by using the command line interface

At the command prompt, type:

- add nd6 <neighbor> <mac> <ifnum> [-vlan <integer>]
- show nd6

Example

```
> add nd6 2001::1 00:04:23:be:3c:06 1/1 –vlan 1
 Done
> show nd6
   Neighbor              MAC-Address(Vlan, Interface)      State       TIME

 Done
```

To add an IPv6 neighbor by using the configuration utility

Navigate to System > Network > IPv6 Neighbors, and add a new IPv6 neighbor.

Removing IPv6 Neighbors

Updated: 2013-08-28

To remove a neighbor discovery entry by using the command line interface

At the command prompt, type:

rm nd6 <Neighbor> -vlan <VLANID>

Example

```
 rm nd6 3ffe:100:100::1 -vlan 1
```

To remove all neighbor discovery entries by using the command line interface

At the command prompt, type:

clear nd6

To remove a neighbor discovery entry by using the configuration utility

Navigate to System > Network > IPv6 Neighbors, delete the IPv6 neighbor.

To remove all neighbor discovery entries by using the configuration utility

Navigate to System > Network > IPv6 Neighbors, and click Clear.

Configuring IP Tunnels

Sep 29, 2016

An IP Tunnel is a communication channel, that can be created by using encapsulation technologies, between two networks that do not have a routing path. Every IP packet that is shared between the two networks is encapsulated within another packet and then sent via the tunnel.

The NetScaler appliance implements IP Tunneling in the following ways:

- NetScaler as an Encapsulator (Load Balancing with DSR mode)
- NetScaler as a Decapsulator

NetScaler as an Encapsulator (Load Balancing with DSR Mode)

Consider an organization that has multiple data centers across different countries, where the NetScaler maybe at one location and the back-end servers are located in a different country. In essence, the NetScaler and the back-end servers are on different networks and are connected via a router.

When you configure Direct Server Return (DSR) on this NetScaler, the packet sent from the source subnet is encapsulated by the NetScaler and sent via a router and tunnel to the appropriate back-end server. The back-end server decapsulates the packet and responds directly to the client, without allowing the packet to pass via the NetScaler.

NetScaler as a Decapsulator

Consider an organization having multiple data centers each having NetScalers and back-end servers. When a packet is sent from data center A to data center B it is usually sent via an intermediary, say a router or another NetScaler. The NetScaler processes the packet and then forwards the packet to the back-end server. However, if an encapsulated packet is sent, the NetScaler must be able to decapsulate the packet before sending it to the back-end servers. To enable the NetScaler to function as a decapsulator, a tunnel is added between the router and the NetScaler. When the encapsulated packet, with additional header information, reaches the NetScaler, the data packet is decapsulated i.e. the additional header information is removed, and the packet is then forwarded to the appropriate back-end servers.

The NetScaler can also be used as a decapsulator for the Load Balancing feature, specifically in scenarios when the number of connections on a vserver exceeds a threshold value and all the new connections are then diverted to a back-up vserver.

This section includes the following details:

Creating IP Tunnels

To create an IP tunnel by using the command line interface

At the command prompt type:

- add iptunnel <name> <remote> <remoteSubnetMask> <local> -type -protocol (ipoverip | GRE) -ipsecprofile <name>
- show iptunnel

Note: While configuring an IP tunnel in a cluster setup, the local IP address must be a striped SNIP or MIP address.

To remove an IP tunnel by using the command line interface

To remove an IP tunnel, type the rm iptunnel command and the name of the tunnel.

To create an IP Tunnel by using the configuration utility

Navigate to System > Network > IP Tunnels, add a new IP tunnel.

To create an IPv6 tunnel by using the command line interface

At the command prompt type:

- add ip6tunnel <name> <remoteIp> <local>
- show ip6tunnel

To remove an IPv6 tunnel by using the command line interface

To remove an IPv6 tunnel, type the rm ip6tunnel command and the name of the tunnel.

To create an IPv6 Tunnel by using the configuration utility

Navigate to System > Network > IP Tunnels > IPv6 Tunnels, and add a new IPv6 tunnel.

Customizing IP Tunnels Globally

Updated: 2013-10-31

By globally specifying the source IP address, you can assign a common source IP address across all tunnels. Also, because fragmentation is CPU-intensive, you can globally specify that the NetScaler appliance drop any packet that requires fragmentation. Alternatively, if you would like to fragment all packets as long as a CPU threshold value is not reached, you can globally specify the CPU threshold value.

To globally customize IP tunnels by using the command line interface

At the command prompt, type the following commands to globally customize IP tunnels and verify the configuration:

- set ipTunnelParam -srcIP <sourceIPAddress> -srcIPRoundRobin (YES | NO)-dropFrag [YES | NO] -dropFragCpuThreshold <Positive integer>
- show ipTunnelParam

Example

```
> set iptunnelparam –srcIP 12.12.12.22 -dropFrag Yes –dropFragCpuThreshold 50
 Done
> set iptunnelparam -srcIPRoundRobin YES -dropFrag Yes –dropFragCpuThreshold 50
 Done
```

Note: To create a new MIP or SNIP address to use as the global source IP address, use the add ns ip command before you type the set iptunnelparam command.

To globally customize IP tunnels by using the configuration utility

Navigate to System > Network, in the Settings group, click IPv4 Tunnel Global Settings.

1. Navigate to System > Network.
2. In the details pane, in the Settings group, click IPv4 Tunnel Global Settings.
3. In the Configure IP Tunnel Global Parameters dialog box, set the parameters. For a description of a parameter, hover the

mouse cursor over the corresponding field.

4. Click OK and then click Close.

To globally customize IPv6 tunnels by using the command line interface

At the command prompt, type the following commands to globally customize IPv6 tunnels and verify the configuration:

- set ip6tunnelparam -srcIP <IPv6Address> -srcIPRoundRobin (YES | NO)-dropFrag [YES | NO] -dropFragCpuThreshold <Positive integer>
- show ip6tunnelparam

Note: To create a new VIP6 or SNIP6 address to use as the global source IP address, use the add ns ip6 command before you type the set ip6tunnelparam command.

To globally customize IPv6 tunnels by using the configuration utility

Navigate to System > Network, in the Settings group, click IPv6 Tunnel Global Settings.

GRE Payload Options in a GRE IP Tunnel

For a configured GRE IP tunnel, the NetScaler appliance encapsulates the entire Layer 2 packet, including the Ethernet header and the VLAN header (dot1q VLAN tag). IP GRE tunnels between NetScaler appliances and some 3rd party devices might not be stable, because these 3rd party devices are not programmed to process some or the Layer 2 packet headers. To configure a stable IP GRE tunnel between a NetScaler appliance and a 3rd party device, you can use the GRE payload parameter of the GRE IP tunnel command set. GRE payload setting can also be applied to a GRE with IPSec tunnel.

You can set the GRE payload parameter to do one of the following before the packet is sent through the GRE tunnel:

Ethernet with DOT1Q. Carry the Ethernet header as well the VLAN header. This is the default setting. For a tunnel bound to a netbridge, inner Ethernet header and VLAN header contains information from the ARP and bridge table of the NetScaler appliance. For a tunnel set as a next hop to a PBR rule, Inner Ethernet destination MAC address is set to zero and the VLAN header specifies the default VLAN. The encapsulated (GRE) packet sent from the NetScaler tunnel end point has the following format:

Outer Ethernet Header	Outer IP Header	GRE Header	Inner Ethernet	Inner VLAN header	Inner IP/IPv6/ARP header	Inner TCP/UDP Header	Payload

Ethernet. Carry the Ethernet header but drop the VLAN header. Because the packets do not carry any VLAN information in the tunnel, for a tunnel with this setting and bound to a netbridge, you must bind an appropriate VLAN to the netbridge so that on receiving any packets on the tunnel, the NetScaler can forward these packet to the specified VLAN. If the tunnel is set as a next hop in a PBR rule, the NetScaler routes the packets that are received on the tunnel. The encapsulated (GRE) packet sent from the NetScaler tunnel end point has the following format:

Outer Ethernet header	Outer IP header	GRE Header	Inner Ethernet header	Inner IP/IPv6/ARP header	Inner TCP/UDP header	Payload

IP. Drop the Ethernet header as well as the VLAN header. Because tunnels with this setting do not carry Layer 2 headers, these tunnels cannot be bound to a netbridge but can be set as a next hop in a PBR rule. The peer tunnel endpoint device on receiving the packet either consumes or routes it. The encapsulated (GRE) packet sent from the NetScaler tunnel end

point has the following format:

To drop Layer 2 headers of packets in a GRE IP tunnel by using the NetScaler command line

- **add ipTunnel** <name> <remote> <remoteSubnetMask> <local> [-**protocol** <GRE> [-**vlan** <positive_integer>]] [-**grepayload** <grepayload>] [-**ipsecProfileName** <string>]
- **show iptunnel** <tunnelname>

Example COPY

```
> add iptunnel IPTUNNEL-1 203.0.113.133 255.255.255.0 198.51.100.15 –protocol GRE –grepayload Ethernet -ipsecProfileName IPTUN

Done
```

IPv6 Traffic through GRE IPV4 Tunnels

The NetScaler appliance supports transferring IPv6 traffic through an IPV4 GRE tunnel. This feature can be used for enabling communication between Isolated IPv6 networks without upgrading the IPv4 infrastructure between them.

For configuring this feature, you associate a PBR6 rule with the configured IPv4 GRE tunnel through which you want the NetScaler to send and receive IPv6 traffic. The source IPv6 address and destination IPv6 address parameters of the PBR6 rule specify the IPv6 networks whose traffic is to traverse the IPv4 GRE tunnel.

Note: IPSec protocol is not supported on GRE IPv4 tunnels that are configured to transfer IPv6 packets.

To create a GRE IPv4 tunnel by using the NetScaler command line

At the command prompt, type:

- add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol GRE
- show ipTunnel <name>

To associate a PBR6 rule with a GRE IPv4 tunnel by using the NetScaler command line

- add ns pbr6 <pbrName> ALLOW –srcIPv6 <network-range> -dstIPv6 <network-range> -ipTunnel <tunnelName>
- show pbr

Example

In the following sample configuration, GRE IP tunnel TUNNEL-V6onV4 is created with remote tunnel endpoint IP address 10.10.6.30 and local tunnel endpoint IP address 10.10.5.30. The tunnel is then bound to pbr6 PBR6-V6onV4. The srcIPv6 specifies the IPv6 network connected to the local endpoint and destIPv6 specifies the IPv6 network connected to the remote endpoint. The traffic from these Ipv6 networks are allowed to traverse through the GRE IPv4 tunnel.

```
> add ipTunnel TUNNEL-V6onV4 10.10.6.30 255.255.255.255 10.10.5.30 -protocol GRE
```

-ipsecProfileName None
Done
> add ns pbr6 PBR6-V6onV4 ALLOW -srcIPv6 = 2001:0db8:1::1-2001:0db8:1::255 -destIPv6 =
1-2001:0db8:4::255 -ipTunnel TUNNEL-V6onV4

Sending Response Traffic Through an IP-IP Tunnel

You can configure a NetScaler appliance to send response traffic through an IP-IP tunnel instead of routing it back to the source. By default, when the appliance receives a request from another NetScaler or a third-party device through an IP-IP tunnel, it routes the response traffic instead of sending it through the tunnel. You can use policy based routes (PBRs) or enable MAC-Based Forwarding (MBF) to send the response through the tunnel.

In a PBR rule, specify the subnets at both end points whose traffic is to traverse the tunnel. Also set the next hop as the tunnel name. When response traffic matches the PBR rule, the NetScaler appliance sends the traffic through the tunnel.

Alternatively, you can enable MBF to meet this requirement, but the functionality is limited to traffic for which the NetScaler appliance stores session information (for example, traffic related to load balancing or RNAT configurations). The appliance uses the session information to send the response traffic through the tunnel.

To create a PBR rule and associate the IP-IP tunnel to it by using the command line interface

At the command prompt, type:

- **add ns pbr** <pbr_name> **ALLOW** -**srcIP** = <local_subnet_range> -**destIP** = <remote_subnet_range> -**ipTunnel** <tunnel_name>
- **apply ns pbrs**
- **show ns pbr** <pbr_name>

To create a PBR rule and associate the IP-IP tunnel to it by using the NetScaler GUI

At the command prompt, type:

1. Navigate to **System** > **Network** > **PBRs**. On the **PBRs** tab, create a **PBR** rule.
2. While creating the PBR, set the **Next Hop Type** to **IP tunnel** and **IP Tunnel Name** to the configured IP-IP tunnel name.

To enable MAC-based forwarding by using the command line interface

At the command prompt, type:

- **enable ns mode MBF**
- **show ns mode**

To enable MAC-based forwarding by using the NetScaler GUI

1. Navigate to **System** > **Settings**, in **Modes and Features**, click **Configure Modes**.
2. On the **Configure Modes** page, select **MAC-based forwarding**.

Consider an example of an IPIP tunnel, NS1-NS2-IPIP, which is set up between two NetScaler appliances NS1 and NS2.

By default, for any request that NS2 receives through the tunnel, its routes the response traffic to the source instead of sending it (to NS1) through the tunnel.

You can configure policy based routes (PBRs) or enable MAC-Based Forwarding (MBF) on NS2 for enabling it to send the response through the tunnel.

In the following sample configuration on NS2, NS1-NS2-IPIP is an IPIP tunnel and NS1-NS2-IPIP-PBR is a PBR rule. For requests (with inner source IP address in the range 10.102.147.0-10.102.147.255 and inner destination IP address in the range 10.102.147.0-10.102.147.255) received by NS2 through the tunnel, NS2 sends the corresponding response through the tunnel (to NS1) instead of routing it to the source. The functionality is limited to the traffic that matches the PBR rule.

Sample Configuration COPY

```
> add iptunnel NS1-NS2-IPIP 192.0.2.99 255.255.255.255 203.0.113.99–protocol IPIP

Done

> add pbr NS1-NS2-IPIP-PBR -srcIP 10.102.147.0-10.102.147.255 –destIP 10.20.1.0-10.20.1.255 –ipTunnel NS1-NS2-IPIP

Done

> apply pbrs

Done
```

Alternatively, MBF can be enabled on NS2. The functionality is limited to traffic for which NS2 stores session information (for example, traffic related to load balancing or RNAT configurations).

Sample Configuration COPY

```
> enable ns mode MBF

Done
```

Interfaces

Feb 13, 2017

Before you begin configuring interfaces, decide whether your configuration can use MAC-based forwarding mode, and either enable or disable this system setting accordingly. The number of interfaces in your configuration is different for the different models of the Citrix NetScaler appliance. In addition to configuring individual interfaces, you can logically group interfaces, using VLANs to restrict data flow within a set of interfaces, and you can aggregate links into channels. In a high availability setup, you can configure a virtual MAC (VMAC) address if necessary. If you use L2 mode, you might want to modify the aging of the bridge table.

When your configuration is complete, decide whether you should enable the system setting for path MTU discovery. NetScaler appliances can be deployed in active-active mode using VRRP. An active-active deployment, in addition to preventing downtime, makes efficient use of all the NetScaler appliances in the deployment. You can use the Network Visualizer tool to view the network configuration of a NetScaler deployment and configure interfaces, channels, VLANs, and bridge groups.

This document includes the following information:

- Configuring MAC-Based Forwarding

- Configuring Active-Active Mode
- Using the Network Visualizer
- Configuring Link Layer Discovery Protocol
- Jumbo Frames

Configuring MAC-Based Forwarding

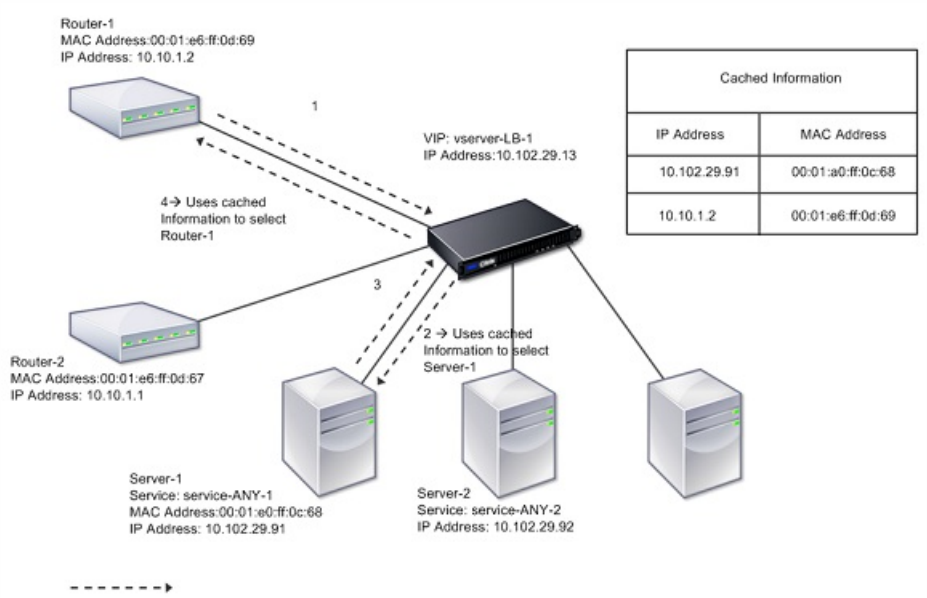
Oct 31, 2013

With MAC-based forwarding (MBF) enabled, when a request reaches the NetScaler appliance, the appliance remembers the source MAC address of the frame and uses it as the destination MAC address for the resulting replies. MAC-based forwarding can be used to avoid multiple-route/ARP lookups and to avoid asymmetrical packet flows. MAC-based forwarding may be required when the NetScaler is connected to multiple stateful devices, such as VPNs or firewalls, because it ensures that the return traffic is sent to the same device that the initial traffic came from.

MAC-based forwarding is useful when you use VPN devices, because it guarantees that all traffic flowing through a VPN passes back through the same VPN device.

The following topology diagram illustrates the process of MAC-based forwarding.

Figure 1. MAC-Based Forwarding Mode



When MAC-based forwarding (MBF) is enabled, the NetScaler caches the MAC address of:

- The source (a transmitting device such as router, firewall, or VPN device) of the inbound connection.
- The server that responds to the requests.

When a server replies through the NetScaler appliance, the appliance sets the destination MAC address of the response packet to the cached address, ensuring that the traffic flows in a symmetric manner, and then forwards the response to the client. The process bypasses the route table lookup and ARP lookup functions. However, when the NetScaler initiates a connection, it uses the route and ARP tables for the lookup function. In a direct server return configuration, you must enable MAC-based forwarding.

For more information about direct server return configurations, see "Load Balancing."

Some deployment topologies may require the incoming and outgoing paths to flow through different routers. MAC-based forwarding would break this topology design.

MBF should be disabled in the following situations:

- **When you configure link load balancing.** In this case, asymmetric traffic flows are desirable because of link costs.
- **When a server uses network interface card (NIC) teaming without using LACP (802.1ad Link Aggregation).** To enable MAC-based forwarding in this situation, you must use a layer 3 device between the NetScaler and server.
  Note: MBF can be enabled when the server uses NIC teaming with LACP, because the virtual interface uses one MAC address.
- When firewall clustering is used. Firewall clustering assumes that ARP is used to resolve the MAC address for inbound traffic. Sometimes the inbound MAC address can be a non-clustered MAC address and should not be used for inbound packet processing.

When MBF is disabled, the NetScaler uses L2 or L3 connectivity to forward the responses from servers to the clients. Depending on the route table, the routers used for outgoing connection and incoming connection can be different. In the case of reverse traffic (response from the server):

- If the source and destination are on different IP subnets, the NetScaler uses the route lookup to locate the destination.
- If the source is on the same subnet as the destination, the NetScaler looks up the ARP table to locate the network interface and forwards the traffic to it. If the ARP table does not exist, the NetScaler requests the ARP entries.

To enable or disable MAC-based forwarding by using the command line interface

At the command prompt, type:

- enable ns mode MBF
- disable ns mode MBF

To enable or disable MAC-based forwarding by using the configuration utility

1. Navigate to System > Settings, in the Modes and Features group, click Configure modes.
2. Select or clear the MAC-based forwarding option.

Configuring Network Interfaces

Nov 13, 2015

Network interfaces in the NetScaler appliance are numbered in <slot>/<port> notation. After configuring your interfaces, you should display the interfaces and their settings to verify the configuration. You can also display this information to troubleshoot a problem in the configuration.

To manage the network interfaces, you might have to enable some interfaces and disable others. You can reset an interface to renegotiate its settings. You can clear the accumulated statistics for an interface. To verify the configuration, you can display the interface settings. You can display the statistics for an interface to evaluate its health.

Setting the Network Interface Parameters

Updated: 2013-09-06

The network interface configuration is neither synchronized nor propagated. For an HA pair, you must perform the configuration on each unit independently.

To set the network interface parameters by using the command line interface

At the command prompt, type:

- set interface <id> [-speed <speed>] [-duplex <duplex>] [-flowControl <flowControl>] [-autoneg (DISABLED | ENABLED)] [-haMonitor (ON | OFF)] [(ON | OFF)] [-tagall (ON | OFF)] [-lacpMode <lacpMode>] [-lacpKey<positive_integer>] [-lacpPriority <positive_integer>] [-lacpTimeout (LONG | SHORT)] [-ifAlias <string>] [-throughput <positive_integer>][-bandwidthHigh <positive_integer> [-bandwidthNormal <positive_integer>]]
- show interface [<id>]

Example

```
> set interface 1/8 -duplex full
 Done
```

To set the network interface parameters by using the configuration utility

Navigate to System > Network > Interfaces, select the network interface that you want to modify (for example, 1/8), click Edit, and then set the parameters.

Enabling and Disabling Network Interfaces

Updated: 2013-08-29

By default, the network interfaces are enabled. You must disable any network interface that is not connected to the network, so that it cannot send or receive packets. Disabling a network interface that is connected to the network in a high availability setup can cause failover.

For more information about high availability, see "."

To enable or disable a network interface by using the command line interface

At the command prompt, type one of the following pairs of commands to enable or disable an interface and verify the setting:

- enable interface <interface_num>
- show interface <interface_num>
- disable interface <interface_num>
- show interface <interface_num>

Example

```
> enable interface 1/8
 Done
> show interface 1/8
      Interface 1/8 (Gig Ethernet 10/100/1000 MBits) #2
      flags=0x4004000 <ENABLED, DOWN, BOUND to LA/1, down, autoneg, 802.1q>
      MTU=1514, MAC=00:d0:68:15:fd:3d, downtime 906h58m40s
      Requested: media UTP, speed AUTO, duplex FULL, fctl OFF, throughput 0
      RX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
      TX: Pkts(0) Bytes(0) Errs(0) Drops(0) Stalls(0)
      NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
      Bandwidth thresholds are not set.
Done
```

To enable or disable a network interface by using the configuration utility

1. Navigate to System > Network > Interfaces.
2. Select the network interface and, in the Action list, select Enable or Disable.

Resetting Network Interfaces

Updated: 2013-09-30

Network interface settings control properties such as duplex and speed. To renegotiate the settings of a network interface, you must reset it.

To reset a network interface by using the command line interface

At the command prompt, type the following commands to reset an interface and verify the setting:

- reset interface <interface_num>
- show interface <interface_num>

Example

```
> reset interface 1/8
 Done
```

To reset a network interface by using the configuration utility

1. Navigate to System > Network > Interfaces.

2. Select the network interface and, in the Action list, select Reset Interface.

Monitoring a Network Interface

Updated: 2013-08-29

You can display network interface statistics to monitor parameters such as packets sent and packets received, throughput, Link Aggregate Control Protocol (LACP) data units, and errors, and use the information to check the health of the network interface. You can clear the statistics of a network interface to monitor its statistics from the time the statistics are cleared.

To display the statistics of the network interfaces by using the command line interface

At the command prompt, type:

stat interface <interface_num>

To display the statistics of an Interface by using the configuration utility

Navigate to System > Network > Interfaces, select the network interface, and click Interface Statistics.

To clear a network interface's statistics by using the command line interface

At the command prompt, type:

clear interface <interface_num>

Example

```
> clear interface 1/8
 Done
```

To clear a network interface's statistics by using the configuration utility

1. Navigate to System > Network > Interfaces.
2. Select the network interface and, in the Action list, select Clear Statistics.

Configuring Forwarding Session Rules

Jun 11, 2014

By default, the NetScaler appliance does not create session entries for traffic that it only forwards (L3 mode). For a case in which a client request that the appliance forwards to a server results in a response that has to return by the same path, you can create a forwarding-session rule. A forwarding-session rule creates forwarding-session entries for traffic that originates from or is destined for a particular network and is forwarded by the NetScaler. You can create forwarding session rules for IPv4 traffic as well as IPv6 traffic.

When configuring an IPv4 forwarding-session rule, you can specify either an IPv4 network address or an extended ACL as the condition for identifying IPv4 traffic for which to create a forwarding-session entry:

- **Network address**. When you specify an IPv4 network address, the appliance creates forwarding sessions for IPv4 traffic whose source or destination matches the network address.
- **Extended ACL rule**. When you specify an extended ACL rule, the appliance creates forwarding sessions for IPv4 traffic that matches the conditions specified in the extended ACL rule.

When configuring an IPv6 forwarding-session rule, you can specify either an IPv6 prefix or an ACL6 as the condition for identifying IPv6 traffic for which to create a forwarding-session entry:

- **IPv6 prefix**. When you specify an IPv6 prefix, the appliance creates forwarding sessions for IPv6 traffic whose source or destination matches the IPv6 prefix.
- **ACL6 rule**. When you specify an ACL6 rule, the appliance creates forwarding sessions for IPv6 traffic that matches the conditions specified in the ACL6 rule.

To create an IPv4 forwarding session rule by using the command line interface

At the command prompt, type the following commands to create a forwarding-session rule and verify the configuration:

- add forwardingSession <name> [<network> <netmask>] | [-aclname <string>] -connfailover (ENABLED | DISABLED)
- show forwardingSession

Example

A network address as the condition:

```
> add forwardingSession fs-nw-1 10.102.105.51 255.255.255.255
 Done
```

An ACL as the condition:

```
> add forwardingSession fs-acl-1 acl1
 Done
```

To configure an IPv4 forwarding session rule by using the configuration utility

Navigate to System > Network > Forwarding Sessions, add a new IPv4 forwarding session, or edit an existing forwarding session.

To create an IPv6 forwarding session rule by using the command line interface

At the command prompt, type the following commands to create a forwarding-session rule and verify the configuration:

- add forwardingSession <name> [<IPv6 prefix>] | [-acl6name <string>]

- show forwardingSession

Example

An IPv6 prefix as the condition:

```
> add forwardingSession fsv6-pfx-1 3ffe::/64
 Done
```

An ACL6 rule as the condition:

```
> add forwardingSession fsv6-acl6-1 –acl6name ACL6-FS
 Done
```

To configure an IPv6 forwarding session rule by using the configuration utility

Navigate to System > Network > Forwarding Sessions, add a new IPv6 forwarding session, or edit an existing forwarding session.

Understanding VLANs

Mar 19, 2012

A NetScaler appliance supports Layer 2 port and IEEE 802.1q tagged VLANs. VLAN configurations are useful when you need to restrict traffic to certain groups of stations. You can configure a network interface as a part of multiple VLANs by using IEEE 802.1q tagging.

You can configure VLANs and bind them to IP subnets. The NetScaler then performs IP forwarding between these VLANs (if it is configured as the default router for the hosts on these subnets).

The NetScaler supports the following types of VLANs:

Port-Based VLANs. The membership of a port-based VLAN is defined by a set of network interfaces that share a common, exclusive Layer 2 broadcast domain. You can configure multiple port-based VLANs. By default, all network interfaces on the NetScaler are members of VLAN 1.

If you apply 802.1q tagging to the port, the network interface belongs to a port-based VLAN. Layer 2 traffic is bridged within a port-based VLAN, and Layer 2 broadcasts are sent to all members of the VLAN if Layer 2 mode is enabled. When you add an untagged network interface as a member of a new VLAN, it is removed from its current VLAN.

Default VLAN. By default, the network interfaces on the NetScaler are included in a single, port-based VLAN as untagged network interfaces. This VLAN is the default VLAN. It has a VLAN ID (VID) of 1. This VLAN exists permanently. It cannot be deleted, and its VID cannot be changed.

When you add a network interface to a to a different VLAN as an untagged member, the network interface is automatically removed from the default VLAN. If you unbind a network interface from its current port-based VLAN, it is added to the default VLAN again.

Tagged VLANs. 802.1q tagging (defined in the IEEE 802.1q standard) allows a networking device (such as the NetScaler) to add information to a frame at Layer 2 to identify the VLAN membership of the frame. Tagging allows network environments to have VLANs that span multiple devices. A device that receives the packet reads the tag and recognizes the VLAN to which the frame belongs. Some network devices do not support receiving both tagged and untagged packets on the same network interface—in particular, Force10 switches. In such cases, you need to contact customer support for assistance.

The network interface can be a tagged or untagged member of a VLAN. Each network interface is an untagged member of one VLAN only (its native VLAN). This network interface transmits the frames for the native VLAN as untagged frames. A network interface can be a part of more than one VLAN if the other VLANs are tagged.

When you configure tagging, be sure to match the configuration of the VLAN on both ends of the link. The port to which the NetScaler connects must be on the same VLAN as the NetScaler network interface.

Note: This VLAN configuration is neither synchronized nor propagated, therefore you must perform the configuration on each unit in an HA pair independently.

Applying Rules to Classify Frames

VLANs have two types of rules for classifying frames:

Ingress rules. Ingress rules classify each frame as belonging only to a single VLAN. When a frame is received on a network interface, the following rules are applied to classify the frame:

- If the frame is untagged, or has a tag value equal to 0, the VID of the frame is set to the port VID (PVID) of the receiving interface, which is classified as belonging to the native VLAN. (PVIDs are defined in the IEEE 802.1q standard.)
- If frame has a tag value equal to FFF, the frame is dropped.
- If the VID of the frame specifies a VLAN of which the receiving network interface is not a member, the frame is dropped. For example, if a packet is sent from a subnet associated with VLAN ID 12 to a subnet associated with VLAN ID 10, the packet is dropped. If an untagged packet with VID 9 is sent from the subnet associated with VLAN ID 10 to a network interface PVID 9, the packet is dropped.

Egress Rules. The following egress rules are applied:
- If the VID of the frame specifies a VLAN of which the transmission network interface is not a member, the frame is discarded.
- During the learning process (defined by the IEEE 802.1q standard), the Src MAC and VID are used to update the bridge lookup table of the NetScaler.
- A frame is discarded if its VID specifies a VLAN that does not have any members. (You define members by binding network interfaces to a VLAN.)

VLANs and Packet Forwarding on the NetScaler

The forwarding process on the NetScaler appliance is similar to that on any standard switch. However, the NetScaler performs forwarding only when Layer 2 mode is on. The key features of the forwarding process are:
- Topology restrictions are enforced. Enforcement involves selecting each network interface in the VLAN as a transmission port (depending on the state of the network interface), bridging restrictions (do not forward on the receiving network interface), and MTU restrictions.
- Frames are filtered on the basis of information in the bridge table lookup in the forwarding database (FDB) table of the NetScaler. The bridge table lookup is based on the destination MAC and the VID. Packets addressed to the MAC address of the NetScaler are processed at the upper layers.
- All broadcast and multicast frames are forwarded to each network interface that is a member of the VLAN, but forwarding occurs only if L2 mode is enabled. If L2 mode is disabled, the broadcast and multicast packets are dropped. This is also true for MAC addresses that are not currently in the bridging table.
- A VLAN entry has a list of member network interfaces that are part of its untagged member set. When forwarding frames to these network interfaces, a tag is not inserted in the frame.
- If the network interface is a tagged member of this VLAN, the tag is inserted in the frame when the frame is forwarded.

When a user sends any broadcast or multicast packets without the VLAN being identified, that is, during duplicate address detection (DAD) for NSIP or ND6 for the next hop of the route, the packet is sent out on all the network interfaces, with appropriate tagging based on either the Ingress and Egress rules. ND6 usually identifies a VLAN, and a data packet is sent on this VLAN only. Port-based VLANs are common to IPv4 and IPv6. For IPv6, the NetScaler supports prefix-based VLANs.

Configuring a VLAN

May 26, 2015

You can implement VLANs in the following environments:

- Single subnet
- Multiple subnets
- Single LAN
- VLANs (no tagging)
- VLANs (802.1q tagging)

If you configure VLANs that have only untagged network interfaces as their members, the total number of possible VLANs is limited to the number of network interfaces available in the NetScaler. If more IP subnets are required with a VLAN configuration, 802.1q tagging must be used.

When you bind a network interface to a VLAN, the network interface is removed from the default VLAN. If the network interfaces need to be a part of more than one VLAN, you can bind the network interfaces to the VLANs as tagged members.

You can configure the NetScaler to forward traffic between VLANs at Layer 3. In this case, a VLAN is associated with a single IP subnet. The hosts in a VLAN that belong to a single subnet use the same subnet mask and one or more default gateways connected to that subnet. Configuring Layer 3 for a VLAN is optional. Layer 3 is used for IP forwarding (inter-VLAN routing). Each VLAN has a unique IP address and subnet mask that define an IP subnet for the VLAN. In an HA configuration, this IP address is shared with the other NetScaler appliances. The NetScaler forwards packets between configured IP subnets (VLANs).

When you configure the NetScaler, you must not create overlapping IP subnets. Doing so impedes Layer 3 functionality.

Each VLAN is a unique Layer 2 broadcast domain. Two VLANs, each bound to separate IP subnets, cannot be combined into a single broadcast domain. Forwarding traffic between two VLANs requires a Layer 3 forwarding (routing) device, such as the NetScaler appliance.

Configuring VLANs in an HA Setup

VLAN configuration for a high-availability setup requires that the NetScaler appliances have the same hardware configuration, and the VLANs configured on them must be mirror images.

The correct VLAN configuration is implemented automatically when the configuration is synchronized between the NetScaler appliances. The result is identical actions on all the appliances. For example, adding network interface 0/1 to VLAN2 adds this network interface to VLAN 2 on all the appliances participating in the high-availability setup.

Note: If you use network-interface-specific commands in an HA setup, the configurations you create are not propagated to the other NetScaler appliance. You must perform these commands on each appliance in an HA pair to ensure that the configuration of the two appliances in the HA pair remains synchronized.

Creating or Modifying a VLAN

Updated: 2013-08-29

To configure a VLAN, you create a VLAN entity, and then bind network interfaces and IP addresses to the VLAN. If you remove a VLAN, its member interfaces are added to the default VLAN.

To create a VLAN by using the command line interface

At the command prompt, type:

add vlan <id> [-aliasName <string>] [-ipv6DynamicRouting (ENABLED | DISABLED)]
Example

```
> add vlan 2 –aliasName “Network A”   Done
```

To bind an interface to a VLAN by using the command line interface

At the command prompt, type:

bind vlan <id> -ifnum <slot/port>
Example

```
> bind vlan 2 -ifnum 1/8   Done
```

To bind an IP address to a VLAN by using the command line interface

At the command prompt, type:

bind vlan <id> -IPAddress <IPAddress> <netMask>
Example

```
> bind vlan 2 -IPAddress 10.102.29.54 255.255.255.0   Done
```

To remove a VLAN by using the command line interface

At the command prompt, type:

rm vlan <id>

To configure a VLAN by using the configuration utility

1. Navigate to System > Network > VLANs, add a new VLAN, or edit an existing VLAN.
2. To bind an IP address to a VLAN, under IP Bindings, select the Active option corresponding to the IP address that you want to bind to the VLAN (for example, 10.102.29.54). The Type column displays the IP address type (such as mapped IP, virtual IP, or subnet IP) for each IP address in the IP Address column.
3. To bind a network interface to a VLAN, under Interface Bindings, select the Active option corresponding to the interface that you want to bind to the VLAN.

Monitoring VLANS

Updated: 2013-08-29

You can display VLAN statistics such as packets received, bytes received, packets sent, and bytes sent, and use the information to identify anomalies and or debug a VLAN.

To view the statistics of a VLAN by using the command line interface

At the command prompt, type:

stat vlan <vlanID>
Example

```
stat vlan 2
```

To view the statistics of a VLAN by using the configuration utility

1. Navigate to System > Network > VLANs.
2. Select the VLAN, and click Statistics.

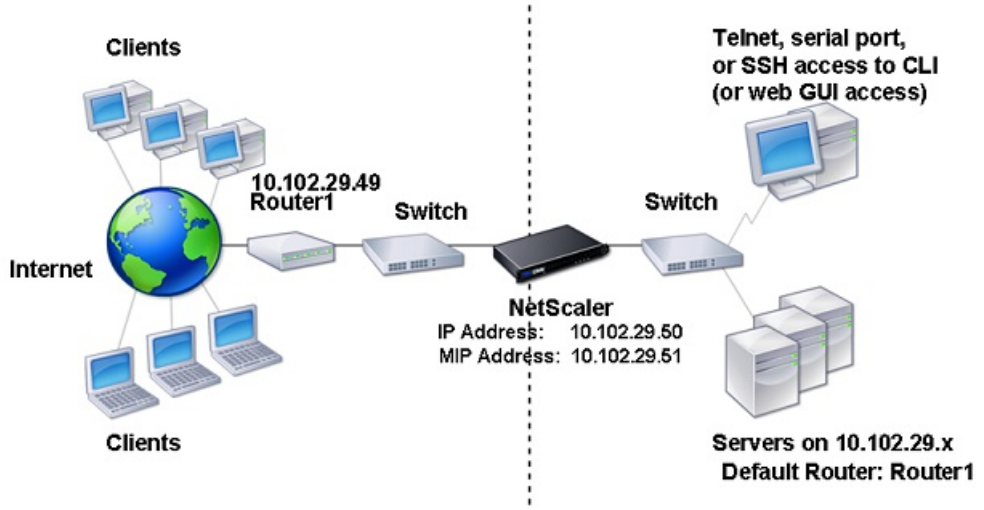
Configuring VLANs on a Single Subnet

Aug 29, 2013

Before configuring a VLAN on a single subnet, make sure that Layer 2 Mode is enabled.

The following figure shows a single subnet environment

Figure 1. VLAN on a Single Subnet



In the above figure:

1. The default router for the NetScaler and the servers is Router 1.
2. Layer 2 mode must be enabled on the NetScaler for the NetScaler to have direct access to the servers.
3. For this subnet, a virtual server can be configured for load balancing on the NetScaler appliance.

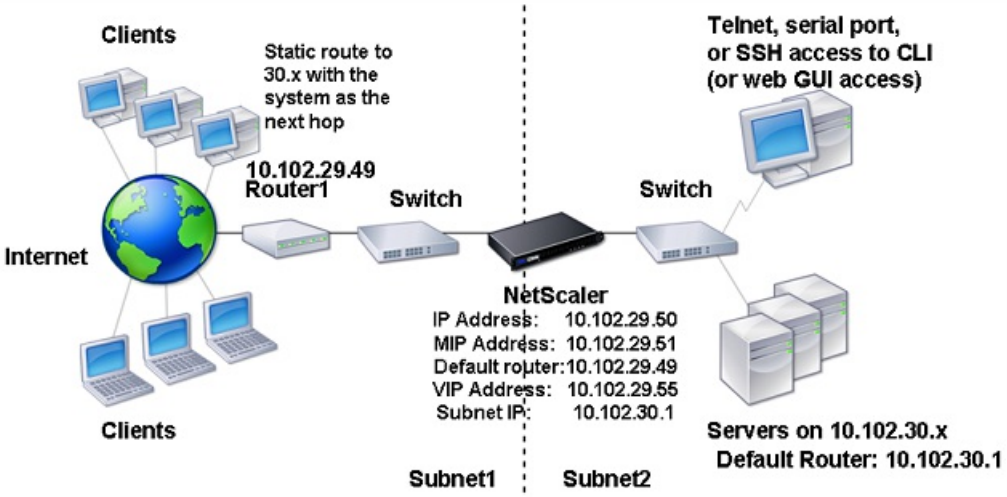
To configure a VLAN on a single subnet, follow the procedures described in Creating or Modifying a VLAN. VLAN configuration parameters are not required, because the network interfaces are members of this VLAN.

Configuring VLANs on Multiple Subnets

Aug 29, 2013

To configure a single VLAN across multiple subnets, you must add a VIP for the VLAN and configure the routing appropriately. The following figure shows a single VLAN configured across multiple subnets.

Figure 1. Multiple Subnets in a Single VLAN



To configure a single VLAN across multiple subnets, perform the following tasks:

1. Disable Layer 2 mode. For the procedure to disable Layer 2 mode, see "Enabling and Disabling Layer 2 Mode."
2. Add a VIP.

   For the procedure to add a VIP, see "Configuring and Managing Virtual IP Addresses (VIPs)."
3. Configure RNAT ID.

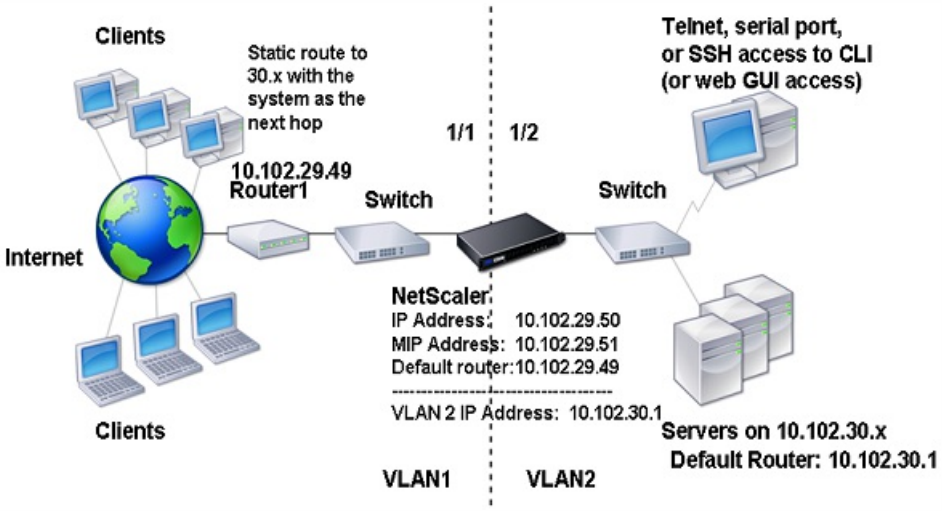
   For the procedure to configure the RNAT ID, see "Configuring RNAT."

Configuring Multiple Untagged VLANs across Multiple Subnets

Aug 29, 2013

In environments with multiple untagged VLANs across multiple subnets, a VLAN is configured for each IP subnet. A network interface is bound to one VLAN only. The following figure shows this configuration.

Figure 1. Multiple Subnets with VLANs - No Tagging



To implement the configuration shown in the above figure, perform the following tasks:

1. Add VLAN 2.
2. Bind the 1/2 network interface of the NetScaler to VLAN 2 as an untagged network interface.
3. Bind the IP address and subnet mask to VLAN 2.

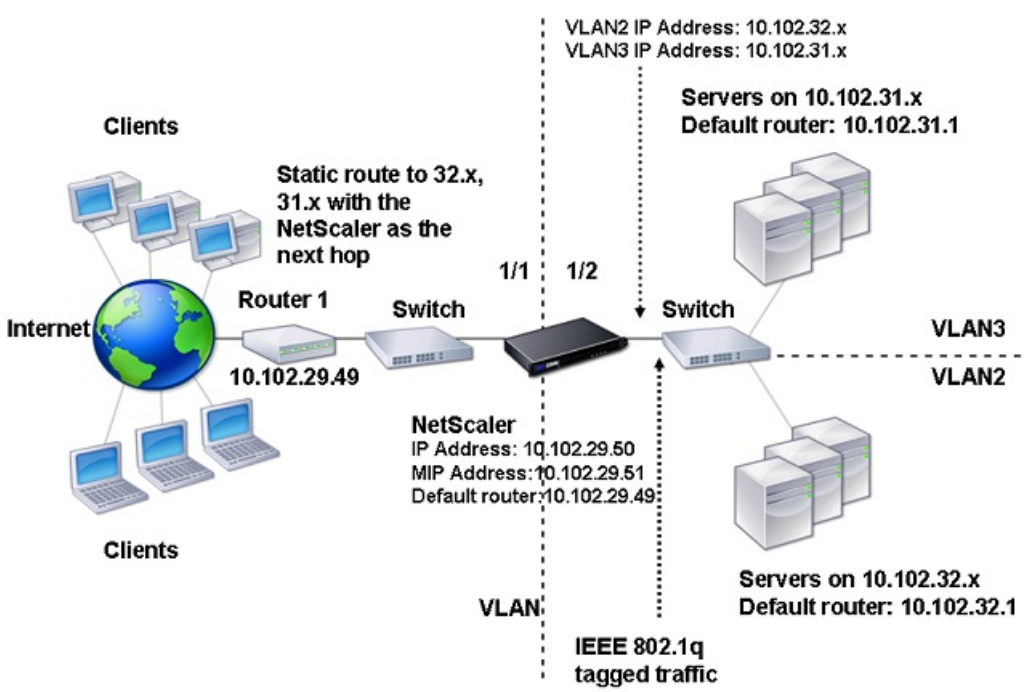
For procedures on these tasks, see Creating or Modifying a VLAN.

Configuring Multiple VLANs with 802.1q Tagging

Feb 13, 2017

For multiple VLANs with 802.1q tagging, each VLAN is configured with a different IP subnet. Each network interface is in one VLAN. One of the VLANs is set up as tagged. The following figure shows this configuration.

Figure 1. Multiple VLANs with IEEE 802.1q Tagging



To implement the configuration shown in the above figure, perform the following tasks:

1. Add VLAN 2.

   For the procedure to create a VLAN, see "Creating or Modifying a VLAN" in Configuring a VLAN.

2. Bind the 1/2 network interface of the NetScaler to VLAN 2 as an untagged network interface.

   For the procedure to bind a network interface to a VLAN, see "Creating or Modifying a VLAN" in Configuring a VLAN.

3. Bind the IP address and netmask to VLAN 2.

   For the procedure to bind an IP address to a VLAN, see "Creating or Modifying a VLAN" in Configuring a VLAN.

4. Add VLAN 3.

   For the procedure to create a VLAN, see "Creating or Modifying a VLAN" in Configuring a VLAN.

5. Bind the 1/2 network interface of the NetScaler to VLAN 3 as a tagged network interface.

   For the procedure to bind a network interface to a VLAN, see "Creating or Modifying a VLAN" in Configuring a VLAN.

   For the procedure to bind a tagged network interface, see "Creating or Modifying a VLAN" in Configuring a VLAN.

6. Bind the IP address and netmask to VLAN 3.

For the procedure to bind an IP address to a VLAN, see "Creating or Modifying a VLAN" in Configuring a VLAN.

Configuring NSVLAN

Jul 07, 2016

NSVLAN is a VLAN to which the NetScaler management IP (NSIP) address's subnet is bound. The NSIP subnet is available only on interfaces that are associated with NSVLAN. By default, NSVLAN is VLAN1, but you can designate a different VLAN as NSVLAN. If you do so, you must reboot the NetScaler appliance for the change to take effect. After the reboot, NSIP subnet traffic is restricted to the new NSVLAN.

The traffic from the NetScaler IP subnet can be tagged (802.1q) with the VLAN ID specified for NSVLAN. You must configure the attached switch interface to tag and allow this same VLAN ID on the connected interface.

If you remove your NSVLAN configuration, the NSIP subnet is automatically bound to VLAN1, restoring the default NSVLAN.

To configure NSVLAN by using the command line interface

At the command prompt, type:

- set ns config -nsvlan <positive_integer> -ifnum <interface_name> ... [-tagged (YES | NO)]
- show ns config

Note: The configuration takes effect after the NetScaler appliance is rebooted.

Example

```
> set ns config -nsvlan 300 -ifnum 1/1 1/2 1/3 -tagged NO
 Done

> save config
 Done
```

To restore the default NSVLAN configuration by using the command line interface

At the command prompt, type:

- unset ns config -nsvlan
- show ns config

Example

```
> unset ns config -nsvlan
 Done
```

To configure NSVLAN by using the configuration utility

Navigate to System > Settings, in the Settings group, click Change NSVLAN Settings.

Setting the MTU on the NSVLAN

By default, the MTU of the NSVLAN is set to 1500 bytes. You can modify this setting to optimize throuhput and network performance. For example, you can configure the NSVLAN to process jumbo frames.

To set the MTU of the NSVLAN by using the NetScaler command line

At the command prompt, type:

- **set vlan** <id> **-mtu** <positive_integer>
- **show vlan** <id>

To set the MTU of the NSVLAN by using the NetScaler GUI

Navigate to **System** > **Network** > **VLANs**, open the NSVLAN, and set the **Maximum Transmission Unit** parameter.

Sample Configuration

In the following sample configuration, VLAN 100 is the NSVLAN.

Sample Configuration COPY

```
> set ns config -nsvlan 100 -ifnum 1/1 -tagged no

 Warning: The configuration must be saved and the system rebooted for these settings to take effect

> set vlan 100 -mtu 1600

  Done

> sh vlan

 1)  VLAN ID: 1

     Link-local IPv6 addr:

    fe80::947b:52ff:fead:12d5/64

     Interfaces : 1/2 LO/1

 2)  VLAN ID: 100     VLAN Alias Name:

     MTU: 1600

     Interfaces : 1/1
```

```
    IPs :

        10.102.53.114     Mask: 255.255.255.0

  Done

> save config

  Done
```

Configuring Bridge Groups

Feb 20, 2017

Typically, when you want to merge two or more VLANs into a single domain, you change the VLAN configuration on all the devices in the separate domains. This can be a tedious task. To more easily merge multiple VLANs into a single broadcast domain, you can use bridge groups.

The bridge groups feature works the same way as a VLAN. Multiple VLANS can be bound to a single bridge group, and all VLANs bound to same bridge group form a single broadcast domain. You can bind only Layer 2 VLANs to a bridge group. For Layer 3 functionality, you must assign an IP address to a bridge group.

In Layer 2 mode, a broadcast packet received on an interface belonging to a particular VLAN is bridged to other VLANs that belong to the same bridge group. In the case of a unicast packet, the NetScaler appliance searches its bridge table for the learned MAC addresses of all the VLANs belonging to same bridge group.

In Layer 3 forwarding mode, an IP subnet is bound to a bridge group. The NetScaler accepts incoming packets belonging to the bound subnet and forwards the packets only on VLANs that are bound to the bridge group.

IPv6 routing can be enabled on a configured bridge group.

> **Note**
>
> Bridge Group feature and Bridge BPDU mode cannot work together.

To add a bridge group and bind VLANs by using the command line interface

To add a bridge group and bind VLANs and verify the configuration, type the following commands:

- add bridgegroup <id> [-ipv6DynamicRouting (ENABLED | DISABLED)]
- show bridgegroup <id>
- bind bridgegroup <id> -vlan <positive_integer>
- show bridgegroup <id>

Example

```
> add bridgegroup 12
Done
```

To remove a bridge group by using the command line interface

At the command prompt, type:

rm bridgegroup <id>

Example

rm bridgegroup 12

To configure a bridge group by using the configuration utility

Navigate to System > Network > Bridge Groups, add a new bridge group, or edit an existing bridge group.

Configuring VMACs

Sep 07, 2015

The primary and secondary nodes in a high availability (HA) setup share the Virtual MAC address (VMAC) floating entity. The primary node owns the floating IP addresses (such as MIP, SNIP, and VIP) and responds to ARP requests for these IP addresses with its own MAC address. Therefore, the ARP table of an external device, such as an upstream router, is updated with the floating IP address and the MAC address of the primary node.

When a failover occurs, the secondary node takes over as the new primary node. The former secondary node uses Gratuitous ARP (GARP) to advertise the floating IP addresses that it had learned from the old primary node. The MAC address that the new primary node advertises is the MAC address of its own network interface. Some devices (a few routers) do not accept these GARP messages. Therefore, these external devices retain the IP address-to-MAC address mapping that the old primary node had advertised. This can result in a GSLB site going down.

Therefore, you must configure a VMAC on both nodes of an HA pair. This means that both nodes have identical MAC addresses. When a failover occurs, the MAC address of the secondary node remains unchanged, and the ARP tables on the external devices do not need to be updated.

For the procedures to configure a VMAC, see "Configuring Virtual MAC Addresses."

Configuring Link Aggregation

Feb 13, 2017

Link aggregation combines data coming from multiple ports into a single high-speed link. Configuring link aggregation increases the capacity and availability of the communication channel between the NetScaler appliance and other connected devices. An aggregated link is also referred to as a "channel." You can configure the channels manually, or you can use Link Aggregation Control Protocol (LACP). You cannot apply LACP to a manually configured channel, nor can you manually configure a channel created by LACP.

When a network interface is bound to a channel, the channel parameters have precedence over the network interface parameters. (That is, the network interface parameters are ignored.) A network interface can be bound only to one channel.

When a network interface is bound to a channel, it drops its VLAN configuration. When network interfaces are bound to a channel, either manually or by LACP, they are removed from the VLANs that they originally belonged to and added to the default VLAN. However, you can bind the channel back to the old VLAN, or to a new one. For example, if you bind the network interfaces 1/2 and 1/3 to a VLAN with ID 2, and then bind them to a channel LA/1, the network interfaces are moved to the default VLAN, but you can bind them back to VLAN 2.

This section includes the following details:

- Configuring Link Aggregation Manually
- Configuring Link Aggregation by using the Link Aggregation Control Protocol
- Configuring Link Redundancy using LACP channels

Configuring Link Aggregation Manually

Updated: 2013-08-29

When you create a link aggregation channel, its state is DOWN until you bind an active interface to it. You can modify a channel at any time. You can remove channels, or you can enable/disable them.

To create a link aggregation channel by using the command line interface

At the command prompt, type:

- add channel <id> [-ifnum <interfaceName> ...] [-state (ENABLED | DISABLED)] [-speed <speed>] [-flowControl <flowControl>] [-haMonitor (ON | OFF)][-tagall (ON | OFF)] [-ifAlias <string>] [-throughput <positive_integer>] [-bandwidthHigh <positive_integer> [-bandwidthNormal <positive_integer>]]
- show channel

Example

```
add channel LA/1 -ifnum 1/8
show channels
```

To bind an interface to or unbind an interface from an existing link aggregation channel by using the command line interface

At the command prompt, type one of the following commands:

- bind channel <id> <interfaceName>
- unbind channel <id> <interfaceName>

Example

```
bind channel LA/1 1/8
```

To modify a link aggregation channel by using the command line interface

At the command prompt, type the set channel command, the channel ID, and the parameters to be changed, with their new values.

To configure a link aggregation channel by using the configuration utility

Navigate to System > Network > Channels, add a new channel, or edit an existing channel.

To remove a link aggregation channel by using the command line interface

Important: When a channel is removed, the network interfaces bound to it induce network loops that decrease network performance. You must disable the network interfaces before you remove the channel.
At the command prompt, type:

```
rm channel <id>
```

Example

```
> rm channel LA/1
 Done
```

To remove a link aggregation channel by using the configuration utility

Important: When a channel is removed, the network interfaces bound to it induce network loops that decrease network performance. You must disable the network interfaces before you remove the channel.
Navigate to System > Network > Channels, select the channel that you want to remove and click Delete.

Configuring Link Aggregation by Using the Link Aggregation Control Protocol

The Link Aggregation Control Protocol (LACP) enables network devices to exchange link aggregation information by exchanging LACP Data Units (LACPDUs). Therefore, you cannot enable LACP on network interfaces that are members of a channel that you created manually.

When using LACP to configure link aggregation, you use different commands and parameters for modifying link aggregation channels than you do for creating link aggregation channels. To remove a channel, you must disable LACP on all interfaces that are part of the channel.

Note: In an High Availability configuration, LACP configurations are neither propagated nor synchronized.

Configuring the LACP System Priority

Updated: 2013-10-01

The LACP system priority determines which peer device of an LACP LA channel can have control over the LA channel. This number is globally applied to all LACP channels on the appliance. The lower the value, the higher the priority.

To configure the LACP system priority by using the command line interface

At the command prompt, type the following commands to set the priority for a standalone appliance and verify the configuration:

- set lacp -sysPriority <positive_integer>
- show lacp

Example:

set lacp -sysPriority 50

To set the priority for a specific cluster node, log on to the cluster IP address and at the command prompt, type the following commands:

- set lacp -sysPriority <positive_integer> -ownerNode <positive_integer>
- show lacp

Example:

set lacp -sysPriority 50 -ownerNode 2

To configure the LACP system priority by using the configuration utility

1. Navigate to System > Network > Interfaces and, in the Action list, select Set LACP.
2. Specify the system priority and the owner node (applicable only for a cluster setup).

Creating Link Aggregation Channels

Updated: 2013-08-29

For creating a link aggregation channel by using LACP, you need to enable LACP and specify the same LACP key on each interface that you want to be the part of the channel. For example, if you enable LACP and set the LACP Key to 3 on interfaces 1/1 and 1/2, a link aggregation channel LA/3 is created and interfaces 1/1 and 1/2 are automatically bound to it.

Note: When enabling LACP on a network interface, you must specify the LACP Key.
By default, LACP is disabled on all network interfaces.

To create an LACP channel by using the command line interface

At the command prompt, type:

- set interface <id> [-lacpMode <lacpMode>] [-lacpKey<positive_integer>] [-lacpPriority <positive_integer>] [-lacpTimeout (LONG | SHORT)]
- show interface [<id>]

To create an LACP channel by using the configuration utility

Navigate to System > Network > Interfaces, open the network interface, and set the parameters.

Modifying Link aggregation Channels

Updated: 2013-08-29

After you have created an LACP channel by specifying interfaces, you can modify properties of the channel.

To modify an LACP channel using the command line interface

At the command prompt, type:

- set channel <id> [-ifnum <interfaceName> ...] [-state (ENABLED | DISABLED)] [-speed <speed>] [-flowControl

<flowControl>] [-haMonitor (ON | OFF)] [-ifAlias <string>] [-throughput <positive_integer>] [-tagall (ON | OFF)] [-bandwidthHigh <positive_integer> [-bandwidthNormal <positive_integer>]]

- show channel

Example

```
> set channel LA/3 -state ENABLED -speed 10000
 Done
```

To modify an LACP channel by using the configuration utility

Navigate to System > Network > Channels, and modify an existing LACP channel.

Removing a Link Aggregation Channel

Updated: 2013-08-29

To remove a link aggregation channel that was created by using LACP, you need to disable LACP on all the interfaces that are part of the channel.

To remove an LACP channel by using the command line interface

At the command prompt, type:

- set interface <id> -lacpMode Disable
- show interface [<id>]

To remove an LACP channel by using the configuration utility

Navigate to System > Network > Interfaces, open the network interface, and clear the Enable LACP option.

Configuring Link Redundancy using LACP channels

Updated: 2014-04-08

Link Redundancy using LACP channels enables the NetScaler ADC to divide an LACP channel into logical subchannels, with one subchannel active and the others in standby mode. If the active subchannel fails to meet a minimum threshold of throughput, one of the standby subchannels becomes active and takes over.

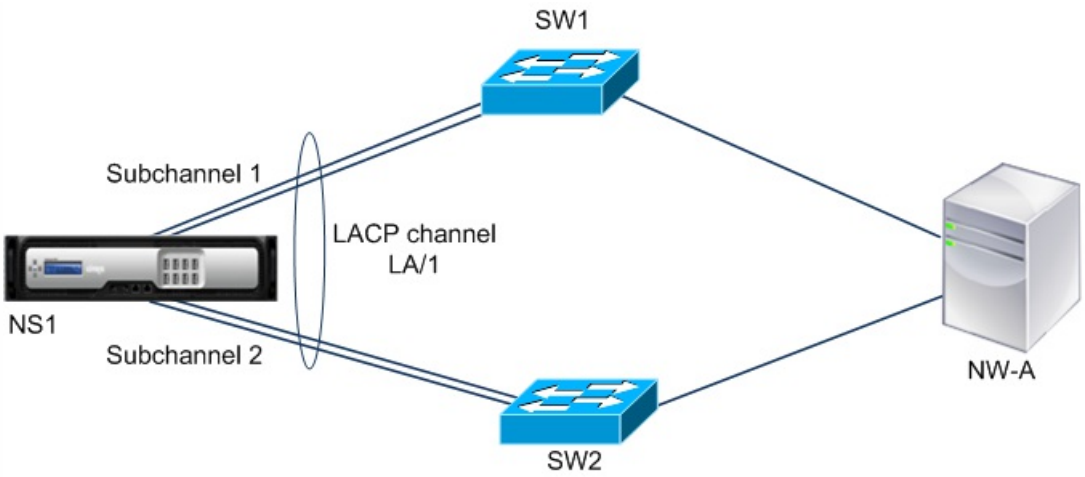
A subchannel is created from links that are part of the LACP channel and are connected to a particular device. For example, for an LACP channel with four interfaces on a NetScaler ADC, with two of the interfaces connected to device A and the other two connected to device B, the ADC creates two logical subchannels, one subchannel with two links to device A, and another subchannel with two links to device B.

To configure link redundancy for an LACP channel, set the lrMinThroughput parameter, which specifies the minimum throughput threshold (in Mbps) to be met by the active subchannel. Setting this parameter automatically creates the subchannels. When the maximum supported throughput of the active channel falls below the lrMinThroughput value, link failover occurs and a standby subchannel becomes active.

If you unset the lrMinThroughput parameter of an LACP channel, or set the value to zero, link redundancy for that channel is disabled, which is the default setting.

Example

Consider an example of link redundancy configured between NetScaler ADC NS1 and switches SW1 and SW2.



NS1 is connected to network device NW-A through SW1 and SW2.

On NS1, LACP channel LA/1 is created from interfaces 1/1, 1/2, 1/3, and 1/4. Interfaces 1/1 and 1/2 of NS1 are connected to SW1, and interfaces 1/3 and 1/4 are connected to SW2. Each of the four links supports a maximum throughput of 1000Mbps.

When the lrMinThroughput parameter is set to some value (say 2000), NS1 creates two logical subchannels from LA/1, one subchannel (say subchannel 1) using interfaces 1/1 and 1/2 (connected to SW1), and the other subchannel (subchannel 2) using interfaces 1/3 and 1/4 (connected to SW2).

NS1 applies an algorithm to make one subchannel (say subchannel 1) active and put the other on standby. NS1 and network device NW-A are accessible to each other through only the active subchannel.

Say subchannel 1 is active, and its maximum supported throughput falls below the lrMinThroughput value (for example, one of its links fails, and the maximum supported throughput falls to 1000 Mbps). Subchannel 2 becomes active and takes over.

Points to Consider when Configuring Link Redundancy in a High Availability setup

In a high availability (HA) configuration, if you want to configure throughput (throughput parameter) based HA failover and link redundancy (lrMinThroughput parameter) on an LACP channel, you must set the throughput parameter to a value less than or equal to that of the lrMinThroughput parameter.

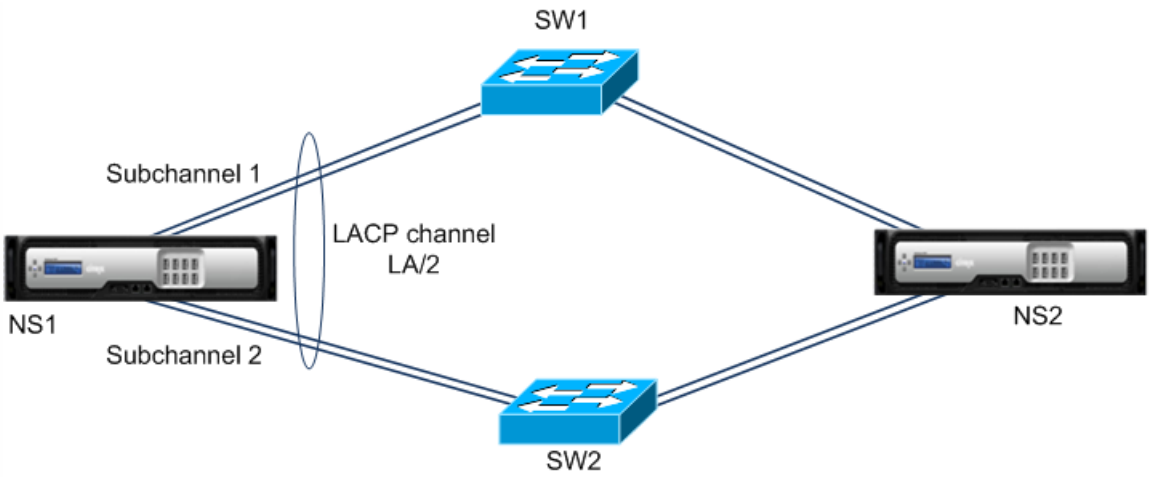
The maximum supported throughput of an LACP channel is calculated as the maximum supported throughput of the active subchannel.

If the throughput parameter value is equal to or less than the lrminthroughput parameter value, HA failover occurs when both of the following conditions exist at the same time:

- None of the subchannels' maximum supported throughput meet the lrMinThroughput parameter value
- The maximum supported throughput of the LACP channel does not meet the throughput parameter value

Consider an example of an HA setup that has NetScaler ADCs NS1 and NS2, with switches SW1 and SW2. NS1 is connected to NS2 through SW1 and SW2.

On NS1, LACP channel LA/1 is created from interfaces 1/1, 1/2, 1/3, and 1/4. Interfaces 1/1 and 1/2 of NS1 are connected to SW1, and interfaces 1/3 and 1/4 are connected to SW2. Each of the four links supports a maximum throughput of 1000 Mbps.



Following are the LACP-parameter settings in this example:

Parameter	Value
Throughput	2000
lrminthroughput	2000

NS1 forms two subchannels from LA/1, one subchannel (say subchannel 1) using interfaces 1/1 and 1/2 (connected to SW1), and the other subchannel (subchannel 2) using interfaces 1/3 and 1/4 (connected to SW2). Each of the two subchannels supports a maximum throughput of 2000 Mbps. Applying an algorithm, NS1 makes one subchannel (say subchannel 1) active and the other standby.

Say subchannel 1 is active, and its maximum supported throughput falls below the lrMinThroughput value (for example, one of its links fails, and maximum supported throughput falls to 1000 Mbps). Subchannel 2 becomes active and takes over. HA failover does not occur, because the maximum supported throughput of the LACP channel is not less than the throughput parameter value:

Maximum supported throughput of the LACP channel = Maximum supported throughput of the active channel = Maximum supported throughput of subchannel 2 = 2000 Mbps

If subchannel 2's maximum supported throughput also falls below the lrminthroughput value (for example, one of its links fails, and the maximum supported throughput falls to 1000 Mbps), HA failover occurs, because the maximum supported throughput of the LACP channel is then less than the throughput parameter value:

To configure link redundancy for a LACP channel by using the command line interface

At the command prompt, type the following commands to configure the channel and verify the configuration:

- set channel <id> -lrMinThroughput <positive_integer>
- show channel

Example

```
> set channel la/1 –lrMinThroughput  2000
Done
> set channel la/2 –throughput 2000 –lrMinThroughput  2000
Done
```

To configure link redundancy for a LACP channel by using configuration utility

1. Navigate to System > Network > Channels.
2. In the details pane, select an LACP channel for which you want to configure link redundancy, and then click Edit.
3. In the Configure LACP channel dialog box, set the lrMinThroughput parameter.
4. Click Close.

Redundant Interface Set

Oct 20, 2016

A redundant interface set is a set of interfaces where one of the interfaces is active and the remaining ones are standby. If the active interface fails, one of the standby interfaces takes over and becomes active.

The following are the main benefits of using redundant interface sets:

- A redundant interface set ensures connection reliability between the NetScaler appliance and a peer device by providing back up links between them.
- Unlike link redundancy using LACP, no configuration is required on the peer device for a redundant interface set. To the peer device, redundant interface set appear as individual interfaces and not as a set or collection.
- In an high availability configuration (HA), redundant interface sets can minimize the number the HA failovers.

A link redundant set is specified in LR/X notation, where X can range from 1 to 4. For example, LR/1.

> **Note**
>
> Redundant Interface Set was formerly known as 'NIC bundling' when first introduced in 10.5 release.

How Redundant Interface Set Works

For a redundant interface set, the NetScaler appliance derives a MAC address on the basis of an internal algorithm and assigns it to the redundant interface set. This MAC address is shared by all the member interfaces and is used only by the active interface at a time. The active interface broadcasts GARP messages, which contains the MAC address assigned to the redundant interface set and not the interface's own physical MAC address. When the current active interface fails and is taken over by another interface, the new active interface sends GARP messages. The peer device updates its forwarding table with the new active interface information. The standby interfaces do not send any GARP messages. The standby interfaces do not send any packets and they drop any packets they receive.

In a redundant interface set, selection of the member interface as active is based on either of the following factors:

- **Redundant interface priority**. This is a parameter of an interface and it defines the priority of the interface in a redundant interface set for the active member selection. This parameter specifies a positive integer. Lower the value higher the priority of active member selection. The member interface with the highest priority (lowest value) is selected as the active interface of the redundant interface set.
- **Binding order of the member interfaces**. If all the member interfaces have the same redundant interface priority, the member interface that was bound first to the redundant interface set is selected as the active interface of the redundant interface set.

In a redundant interface set, active interface selection is triggered in one of the following events:

- When the current active interface fails or you disable it.
- When you set the priority of a standby interface to a value lower than that of the current active interface. The standby interface takes over as the active interface.
- When you bind an interface whose priority is lower than that of the current active interface. The newly bound interface takes over as the active interface.

Points to Consider for Configuring Redundant Interface Sets

Updated: 2015-03-2

Consider the following points before you configure a redundant interface set:

- In a high availability configuration, redundant interface set configurations do not propagate or synchronize to the secondary node.
- In a NetScaler cluster configuration, redundant interface sets are not supported.
- You can configure a maximum of four redundant interface sets.
- You can bind a maximum of 16 interfaces to a redundant interface set.
- Member interfaces of a redundant interface set cannot be bound to another redundant interface set.
- Member interfaces of a redundant interface set cannot be bound to a LA channel.
- LA channels cannot be bound to a redundant interface set.

Configuration Steps

Configuring redundant interface set on a NetScaler appliance consists of the following tasks:

- **Create a redundant interface set**. Use the channel command operation for creating a redundant interface set.

  A link redundant set is specified in LR/X notation, where X can range from 1 to 4. For example, LR/1.

- **Bind interfaces to the redundant interface set**. Associate the desired interfaces with the redundant interface set. An interface cannot be a part of multiple redundant interface sets.
- **(Optional) Set a redundant interface priority on the member interface**. Use the interface command operation for setting the redundant interface priority on a desired member interface of a redundant interface set.

To create a redundant interface set by using the command line interface

At the command prompt:

- add channel <ID>
- show channel <ID>

To bind interfaces to a redundant interface set by using the command line interface

At the command prompt:

- bind channel <ID> <ifnum>
- show channel <ID>

To set a redundant interface priority of an interface by using the command line interface

At the command prompt:

- set interface <ID> -lrsetpriority <positive_integer>
- show interface <ID>

Example

In the following example, redundant interface set LR/1 is created, and interfaces 1/1, 1/2, 1/3, and 1/4 are bound to LR/1. The redundant interface priority is set to a default value of 1024 for all these member interfaces. Output of the show

channel command displays that the interface 1/1 is the current active interface for the redundant interface set lr/1.

```
> add channel lr/1
 Done
> bind channel lr/1 1/1 1/2 1/3 1/4
 Done
> show channel
1)    Interface LR/1 (Link Redundant) #23
      flags=0x100c020 <ENABLED, UP, LINKREDUNDANT, UP, HAMON, 802.1q>
      MTU=1500, native vlan=1, MAC=36:97:a2:b7:6b:a9, uptime 0h00m00s
      Requested: media NONE, speed AUTO, duplex NONE, fctl OFF,
            throughput 0
      Actual: throughput 1000
      LLDP Mode: NONE,
      RX: Pkts(1) Bytes(52) Errs(0) Drops(1) Stalls(0)
      TX: Pkts(2) Bytes(84) Errs(0) Drops(4) Stalls(0)
      NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
      Bandwidth thresholds are not set.
            1/1: UTP-1000-FULL-OFF        UP  0h14m06s    LR Active Member
            1/2: UTP-1000-FULL-OFF        UP  0h14m06s    LR Inactive Member
            1/3: UTP-1000-FULL-OFF        UP  0h14m06s    LR Inactive Member
            1/4: UTP-1000-FULL-OFF        UP  0h14m06s    LR Inactive Member
Done
```

In the following example, redundant interface priority of the member interface 1/4 is set to 100, which is lower than the set redundant interface priority of all the other member interfaces of LR/1.

Output of the show channel command displays that the interface 1/4 is the current active interface for the redundant interface set LR/1.

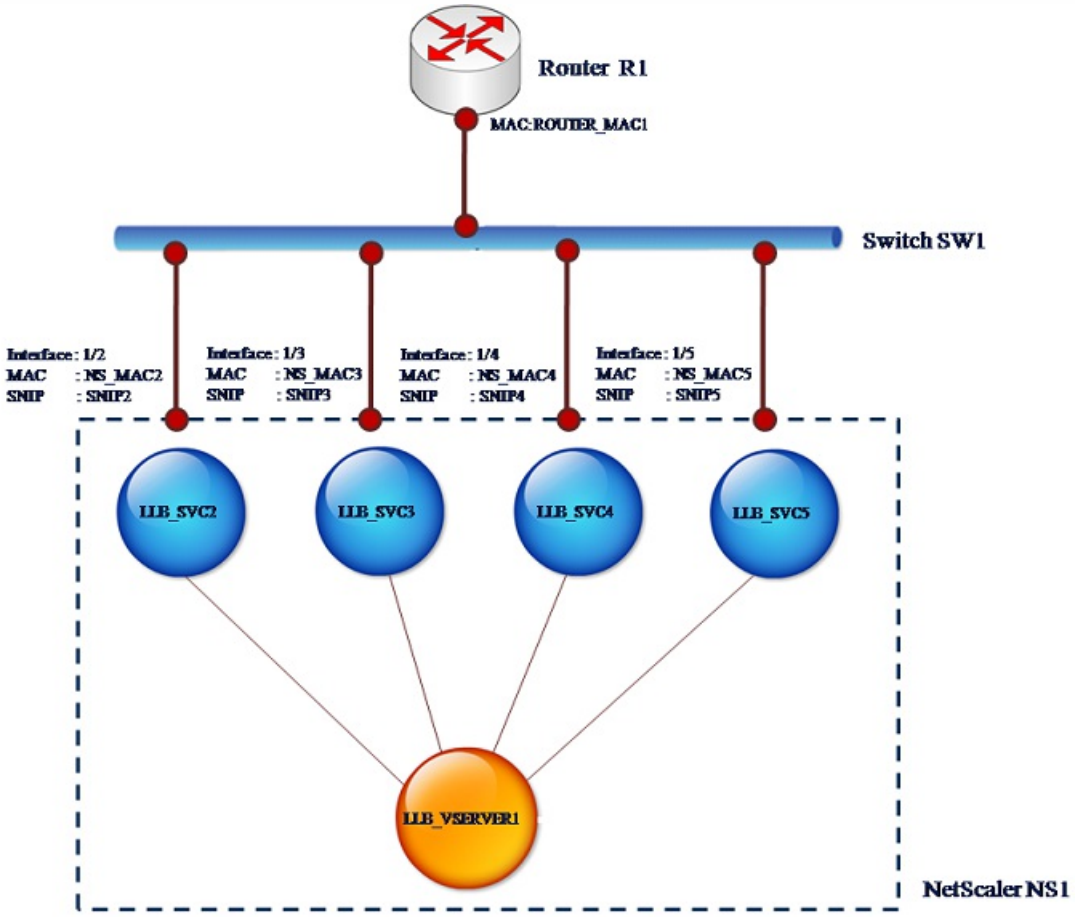
```
> set interface 1/4 -lrsetPriority 100
Done
> show channel
1)     Interface LR/1 (Link Redundant) #23
      flags=0x100c020 <ENABLED, UP, LINKREDUNDANT, UP, HAMON, 802.1q>
      MTU=1500, native vlan=1, MAC=36:97:a2:b7:6b:a9, uptime 0h00m00s
      Requested: media NONE, speed AUTO, duplex NONE, fctl OFF,
            throughput 0
      Actual: throughput 1000
      LLDP Mode: NONE,
      RX: Pkts(1) Bytes(52) Errs(0) Drops(1) Stalls(0)
      TX: Pkts(2) Bytes(84) Errs(0) Drops(4) Stalls(0)
      NIC: InDisc(0) OutDisc(0) Fctls(0) Stalls(0) Hangs(0) Muted(0)
      Bandwidth thresholds are not set.
            1/1: UTP-1000-FULL-OFF        UP  0h14m06s    LR Inactive Member
            1/2: UTP-1000-FULL-OFF        UP  0h14m06s    LR Inactive Member
            1/3: UTP-1000-FULL-OFF        UP  0h14m06s    LR Inactive Member
            1/4: UTP-1000-FULL-OFF        UP  0h14m06s    LR Active Member
Done
```

Binding an SNIP address to an Interface

Aug 29, 2013

You can now bind a NetScaler owned SNIP address to an interface without using Layer 3 VLANs. Any packets related to the SNIP address will go only through the bound interface.

This feature can be useful in a scenario where the upstream switch does not support Link Aggregation channels and you want the NetScaler appliance to load balance traffic, originated from a server, across the four links to the upstream switch as shown in the following illustration.



The following tables describe the example settings for the scenario:

Entity	Name	Value
SNIP addresses on NS1	SNIP2 (for reference purpose only)	10.10.10.2
	SNIP3 (for reference purpose only)	10.10.10.3
	SNIP4 (for reference purpose only)	10.10.10.4
	SNIP5 (for reference purpose only)	10.10.10.5

Entity	Name	Value
LB virtual server on NS1	LB_VSERVER1	-
Transparent monitor on NS1	TRANS_MON	-
LLB services on NS1	LLB_SVC2	10.10.10.240
	LLB_SVC3	10.10.10.120
	LLB_SVC4	10.10.10.60
	LLB_SVC5	10.10.10.30
MAC address of interface 1/2 on NS1	NS_MAC_2 (for reference purpose only)	00:e0:ed:0f:bc:e0
MAC address of interface 1/3 on NS1	NS_MAC_3 (for reference purpose only)	00:e0:ed:0f:bc:df
MAC address of interface 1/4 on NS1	NS_MAC_4 (for reference purpose only)	00:e0:ed:0f:bc:de
MAC address of interface 1/5 on NS1	NS_MAC_5 (for reference purpose only)	00:e0:ed:1c:89:53
IP address of Router R1	Router_IP (for reference purpose only)	10.10.10.1
MAC address of interface of R1	ROUTER_MAC1 (for reference purpose only)	00:21:a1:2d:db:cc

To configure the example settings

1. Add four different SNIPs in different subnet ranges. This is for ARP to be resolved on four different links. For more information on creating a SNIP address, see "Configuring Subnet IP Addresses (SNIPs)."
   Command Line Interface example

   ```
   > add ns ip 10.10.10.2 255.255.255.0 -type SNIP
    Done
   > add ns ip 10.10.10.3 255.255.255.128 –type SNIP
   Done
   > add ns ip 10.10.10.4 255.255.255.192 –type SNIP
   Done
   > add ns ip 10.10.10.5 255.255.255.224 –type SNIP
   Done
   ```
2. Add four different dummy services in the added SNIP subnets. This is to ensure that the traffic is sent out with source IP as one of the four configured SNIPs. For more information on creating a service, see "Configuring Services."
   Command Line Interface example

   ```
   > add service LLB_SVC2 10.10.10.240 any *
    Done
   > add service LLB_SVC3 10.10.10.120 any *
    Done
   > add service LLB_SVC4 10.10.10.60 any *
    Done
   ```

```
> add service LLB_SVC5 10.10.10.30 any *
 Done
```

3. Add a transparent ping monitor for monitoring the gateway. Bind the monitor to each of the configured dummy services. This is to make the state of the services as UP. For more information on creating a transparent monitor, see "Creating and Binding a Transparent Monitor."

   Command Line Interface example

```
> add monitor TRANS_MON ping -destIP 10.10.10.1 -transparent YES
 Done
> bind monitor TRANS_MON LLB_SVC2
 Done
> bind monitor TRANS_MON LLB_SVC3
 Done
> bind monitor TRANS_MON LLB_SVC4
 Done
> bind monitor TRANS_MON LLB_SVC5
 Done
```

4. Add a link load balancing (LLB) virtual server and bind the dummy services to it. For more information on creating an LLB virtual server, see "Configuring an LLB Virtual Server and Binding a Service."

   Command Line Interface example

```
> add lb vserver LLB_VSERVER1 any
 Done
> set lb vserver LLB_VSERVER1 -lbmethod ROUNDROBIN
 Done
> bind lb vserver LLB_VSERVER1 LLB_SVC2
 Done
> bind lb vserver LLB_VSERVER1 LLB_SVC2
 Done
> bind lb vserver LLB_VSERVER1 LLB_SVC2
 Done
> bind lb vserver LLB_VSERVER1 LLB_SVC2
 Done
```

5. Add the LLB virtual server as the default LLB route. For more information on creating an LLB route see "Configuring an LLB Route."

   Command Line Interface example

```
> add lb route 0.0.0.0 0.0.0.0  LLB_VSERVER1
 Done
```

6. Add an ARP entry for each of the dummy services with the MAC address of the gateway. This way the gateway is reachable through these dummy services. For more information on adding an ARP entry, see "Configuring Static ARP."

   Command Line Interface example

```
> add arp -ipaddress 10.10.10.240 -mac 00:21:a1:2d:db:cc -ifnum 1/2
```

```
 Done
> add arp -ipaddress 10.10.10.120 -mac 00:21:a1:2d:db:cc -ifnum 1/3
 Done
> add arp -ipaddress 10.10.10.60 -mac 00:21:a1:2d:db:cc -ifnum 1/4
 Done
> add arp -ipaddress 10.10.10.30 -mac 00:21:a1:2d:db:cc -ifnum 1/5
 Done
```

7. Bind a specific interface to an SNIP by adding an ARP entry for each of these SNIPs. This is to ensure that the response traffic will reach the same interface through which the request went out. For more information on adding an ARP entry, see "Configuring Static ARP."

   Command Line Interface example

```
> add arp -ipAddress 10.10.10.2 -mac 00:e0:ed:0f:bc:e0 -ifnum 1/2
 Done
> add arp -ipAddress 10.10.10.3 -mac 00:e0:ed:0f:bc:df -ifnum 1/3
 Done
> add arp -ipAddress 10.10.10.4 -mac 00:e0:ed:0f:bc:de -ifnum 1/4
 Done
> add arp -ipAddress 10.10.10.5 -mac 00:e0:ed:1c:89:53 -ifnum 1/5
 Done
```

Monitoring the Bridge Table and Changing the Aging time

Aug 29, 2013

NetScaler appliance bridges frames on the basis of bridge table lookup of the destination MAC address and the VLAN ID. However, the appliance performs forwarding only when Layer 2 mode is enabled.

The bridge table is dynamically generated, but you can display it, modify the aging time for the bridge table, and view bridging statistics.

All the MAC entries in the bridge table are updated with the aging time.

To change the aging time by using the command line interface

At the command prompt, type:

- set bridgetable -bridgeAge <positive_integer>
- show bridgetable

Example

```
> set bridgetable -bridgeage 70
 Done
```

To change the aging time by using the configuration utility

1. Navigate to System > Network > Bridge Table.
2. Click Change Ageing Time, and set the Ageing Time (seconds) parameter.
3. In the Action list, select Change Ageing Time, and set the Ageing Time (seconds) parameter.

To view the statistics of a bridge table by using the command line interface

At the command prompt, type:

```
stat bridge
```

To view the statistics of a bridge table by using the configuration utility

Navigate to System > Network > Bridge Table, select the MAC address, and click Statistics.

NetScaler Appliances in Active-Active Mode Using VRRP

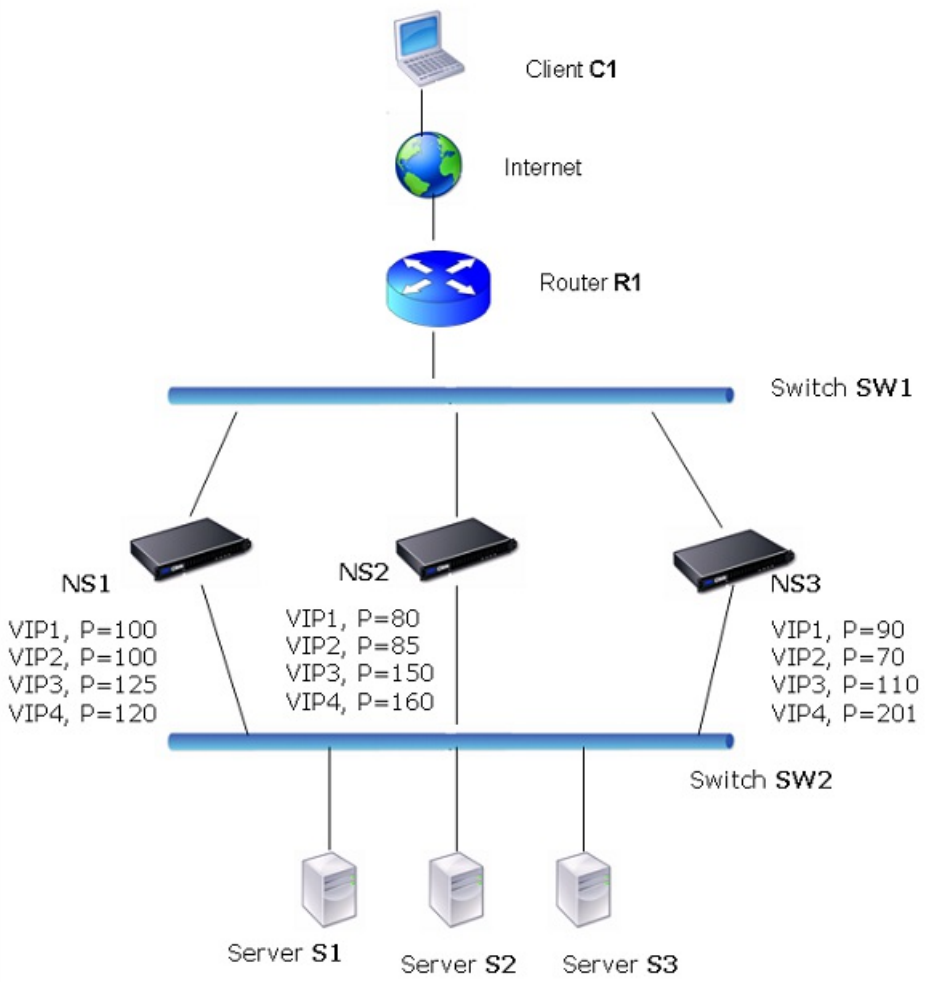
Feb 13, 2017

An active-active deployment, in addition to preventing downtime, makes efficient use of all the NetScaler appliances in the deployment. In active-active deployment mode, the same VIPs are configured on all NetScaler appliances in the configuration, but with different priorities, so that a given VIP can be active on only one appliance at a time.

Note: This feature is supported only on NetScaler nCore builds.
The active VIP is called the master VIP, and the corresponding VIPs on the other NetScaler appliances are called the backup VIPs. If a master VIP fails, the backup VIP with the highest priority takes over and becomes the master VIP. All the NetScaler appliances in an active-active deployment use the Virtual Router Redundancy Protocol (VRRP) protocol to advertise their VIPs and the corresponding priorities at regular intervals.

NetScaler appliances in active-active mode can be configured so that no NetScaler is idle. In this configuration, different sets of VIPs are active on each NetScaler. For example, in the following diagram, VIP1, VIP2, VIP3, and VIP4 are configured on appliances NS1, NS2, and NS3. Because of their priorities, VIP1 and VIP 2 are active on NS1, VIP3 is active on NS2 and VIP 4 is active on NS3. If, for example, NS1 fails, VIP1 on NS3 and VIP2 on NS2 become active.

Figure 1. An Active-Active Configuration



The NetScaler appliances in the above diagram process traffic as follows:

1. Client C1 sends a request to VIP1. The request reaches R1.
2. R1 does not have an ARP entry for VIP1, so it broadcasts an ARP request for VIP1.
3. VIP1 is active in NS1, so NS1 replies with a source MAC address as the VMAC (for example VMAC1) associated with VIP1, and VIP1 as the source IP address.
4. SW1 learns the port for VIP1 from the ARP reply and updates its bridge table.
5. R1 updates the ARP entry with VMAC1 and VIP1.
6. R1 forwards the packet to the VIP1 on NS1.
7. NS1's load balancing algorithm selects server S2, and NS1 opens a connection between one of its SNIP or MIP addresses and S2.
8. S2 replies to the SNIP or MIP on the NetScaler.
9. NS1 sends S2's reply to the client. In the reply, NS1 inserts MAC address of the physical interface as the source MAC address and VIP1 as the source IP address.
10. Should NS1 fail, the NetScaler appliances use the VRRP protocol to select the VIP1 with the highest priority. In this case, VIP1 on NS3 becomes active, and the following two steps update the active-active configuration.
11. NS3 broadcasts a GARP message for VIP1. In the message, VMAC1 is the source MAC address and VIP1 is the source IP address.
12. SW1 learns the new port for VMAC1 from the GARP broadcast and updates its bridge table to send subsequent client requests for VIP1 to NS3. R1 updates its ARP table.

The priority of a VIP can be modified by health tracking. If you enable health tracking, you should make sure that preemption is also enabled, so that a VIP whose priority is lowered can be preempted by another VIP.

In some situations, traffic might reach a backup VIP. To avoid dropping such traffic, you can enable sharing, on a per-node basis, as you create an active-active configuration. Or you can enable the global send to master option. On a node on which sharing is enabled, it takes precedence over send to master.

Base priority (BP-range 1-255) ordinarily determines which VIP is the master VIP, but effective priority (EP) can also affect the determination.

For example, if a VIP on NS1 has a priority of 101 and same VIP on NS2 has a priority of 99, the VIP on NS1 is active. However, if two vservers are using the VIP on NS1 and one of them goes DOWN, health tracking can reduce the EP of VIP on NS1. VRRP then makes the VIP on NS2 the active VIP.

Following are the health tracking options for modifying EP:

- **NONE.** No tracking. EP = BP
- **ALL.** If all virtual servers are UP, then EP = BP. Otherwise, EP = 0.
- **ONE.** If at least one virtual server is UP, then EP = BP. Otherwise, EP = 0.
- **PROGRESSIVE.** If ALL virtual servers are UP, then EP = BP. If ALL virtual servers are DOWN then EP = 0. Otherwise EP = BP (1 - K/N), where N is the total number of virtual servers associated with the VIP and k is the number of virtual servers that are down.

Note: If you specify a value other than NONE, preemption should be enabled, so that the backup VIP with the highest priority becomes active if the priority of the master VIP is downgraded.

Preemption of an active VIP by another VIP that attains a higher priority is enabled by default, and normally should be enabled. In some cases, however, you may want to disable it. Preemption is a per-node setting for each VIP.

Preemption can occur in the following situations:

- An active VIP goes down and a VIP with a lower priority takes its place. If the VIP with the higher priority comes back online, it preempts the currently active VIP.
- Health tracking causes the priority of a backup VIP to become higher than that of the active VIP. The backup VIP then preempts the active VIP.

In the event that traffic reaches a backup VIP, the traffic is dropped unless the sharing option is enabled on the backup VIP. This behavior is a per node setting for each VIP and is disabled by default.

In the figure "An Active-Active Configuration," VIP1 on NS1 is active and VIP1 VIPs on NS2 and NS3 are backups. Under certain circumstances, traffic may reach VIP1 on NS2. If Sharing is enabled on NS2, this traffic is processed instead of dropped.

Configuring Active-Active Mode

Feb 13, 2017

On each NetScaler appliance that you want to deploy in active-active mode, you must add a Virtual MAC (VMAC) and bind the VMAC to a VIP. The VMAC for a given VIP must be same on each appliance. For example, if VIP 10.102.29.5, is created on the appliances, a virtual router ID (VRID) must be created on each NetScaler and bound to VIP 10.102.29.5 on each NetScaler. When you bind a VMAC to a VIP, the NetScaler sends VRRP advertisements to each VLAN that is bound to that VIP. The VMAC can be shared by different VIPs configured on the same NetScaler.

Perform the following tasks on each of the NetScaler appliances to be included in the active-active configuration:

- **Add a VMAC address**. Add a VMAC address by adding a VRID. You can also specify a priority and enable or disable preemption and sharing on this VRID address.
- **Add a VIP address and associate the VMAC's VRID**. Add a VIP address and set the VRID parameter to the newly created VRID. The attributes of the VRID (for example, priority and preemption) are bound to this VIP address.
  Note: The same VIP address must be added to all the other NetScaler appliances.

To add a VMAC address by using theNetScaler command line

At the command prompt, type:

- **add vrID** <id> [-**priority** <positive_integer>] [-**preemption** (**ENABLED** | **DISABLED**)][-**sharing** (**ENABLED** | **DISABLED**)] [-**tracking** <tracking>]
- **show vrid**

To add a VIP address by using the NetScaler command line

At the command prompt, type:

- **add ns ip** <IPv4Address> -type VIP -vrid <value>
- **show ns ip**

To configure a VMAC by using the configuration utility

1. Navigate to **System** > **Network** > **VMAC**, on the **VMAC** tab, add a new VMAC, or edit an existing VMAC.
2. Set the following parameters:
   - Virtual Router ID
   - Priority
   - Tracking
   - Preemption
   - Sharing

To configure a VIP address and associate the VRID to it by using the NetScaler configuration utility

1. Navigate to **System** > **Network** > **IPs**, on the **IPV4s** tab, add an IP address of type VIP.
2. While adding the IP address, select the virtual router ID from the **Virtual Router Id** drop down box.

Sample Configuration

The following sample configuration is for deploying NetScaler appliances NS1 and NS2 in IPv4 active-active mode. VIP address 203.0.113.10 is configured on both NS1 and NS2, with a different priority value on each appliance. On each appliance, this VIP address is bound to a VMAC address. 203.0.113.10 is master on NS2, because its priority (200) on NS2 is higher than on NS1 (100).

```
Settings on NS1

> add vrid 10 –Priority 100 –Preemption Enabled –sharing Enabled

Done

> add ns ip 203.0.113.10 –type VIP –vrid 10

Done

Settings on NS2

> add vrid 30 –Priority 200 –Preemption Enabled –sharing Enabled

Done

> add ns ip 2001:db8::5001 –type VIP –vrid 30

Done
```

Perform the following tasks on each of the NetScaler appliances to be included in the active-active configuration:

- **Add a VMAC6 address**. Add a VMAC6 address by adding a VRID6. You can also specify a priority and enable or disable preemption and sharing on this VRID6 address.
- **Add a VIP6 address**. Add a VIP6 address. Set the VRID6 parameter to the VRID6 of the newly created VMAC6.The attributes of the VMAC6 (for example, priority and preemption) are bound to this VIP6 address.

Note: The same VIP6 address must be added to all the other NetScaler appliances.

To add a VMAC6 address by using the NetScaler command line

At the command prompt, type:

- **add vrID6** <id> [-**priority** <positive_integer>] [-**preemption** (**ENABLED** | **DISABLED**)] [-**sharing** (**ENABLED** | **DISABLED**)]
- **show vrID6**

To add a VIP6 address by using the NetScaler command line

At the command prompt, type:

- **add ns ip6** <IPv6Address> -**type** VIP -**vrid** <value>
- **show ns ip6**

To configure a VMAC6 by using the configuration utility

1. Navigate to **System** > **Network** > **VMAC**, on the **VMAC6** tab, add a new VMAC6, or edit an existing **VMAC6**.
2. Set the following parameters:
   - Virtual Router ID
   - Priority
   - Preemption
   - Sharing

To configure a VIP6 address and associate the VRID to it by using the NetScaler configuration utility

1. Navigate to **System** > **Network** > **IPs**, on the **IPV6s** tab, add an IPv6 address of type VIP.
2. While adding the VIP6 address, select the VRID6 from the **Virtual Router Id** drop down box.

Sample Configuration

The following sample configuration is for deploying NetScaler appliances NS1 and NS2 in IPv6 active-active mode. VIP6 address 2001:db8::5001 is configured on both NS1 and NS2, with a different priority value on each appliance. On each appliance, this VIP6 address is bound to a VMAC6 address. 2001:db8::5001 is master on NS2, because it's priority (200) on NS2 is higher than on NS1 (100).

```
Settings on NS1

> add vrid6 10 –Priority 100 –Preemption Enable –sharing Enable

Done

> add ns ip6 2001:db8::5001 –type VIP –vrid6 10

Done

Settings on NS2

> add vrid6 30 –Priority 200 –Preemption Enable –sharing Enable

Done

> add ns ip6 2001:db8::5001 –type VIP –vrid6 30

Done
```

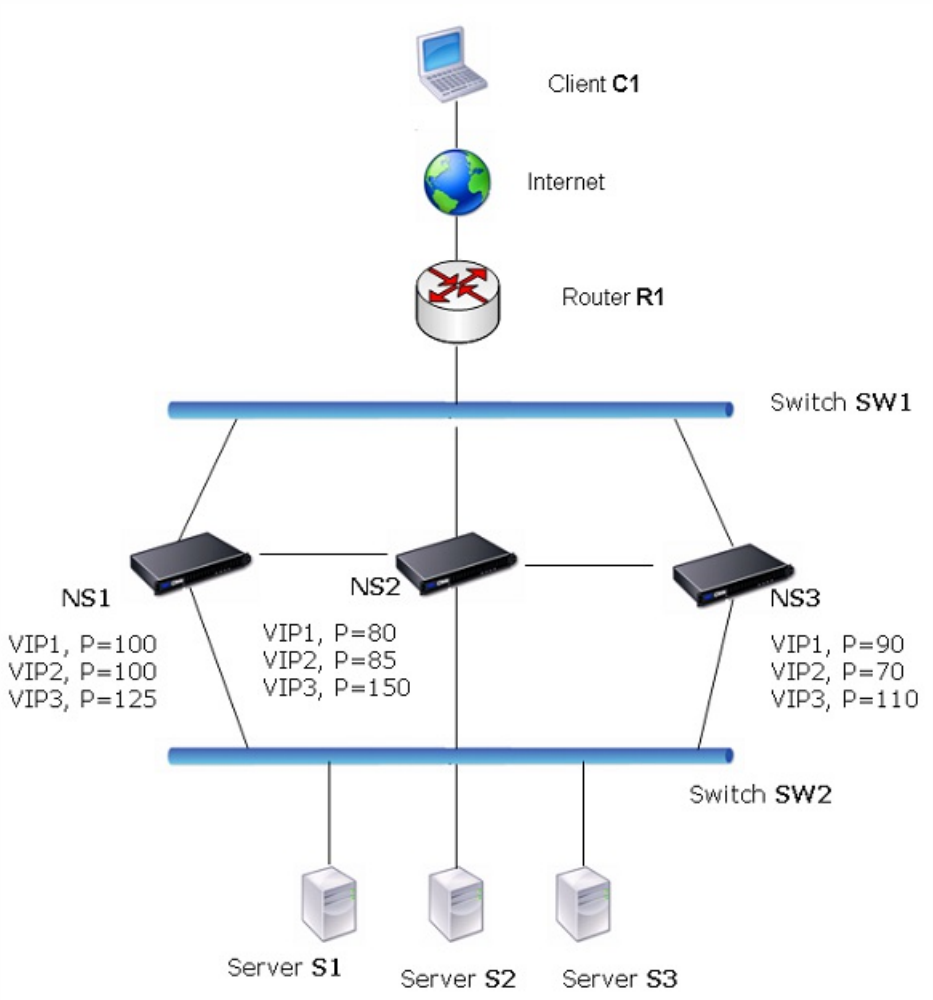
Configuring Send to Master

Jul 04, 2016

Usually, the traffic destined to a VIP reaches the NetScaler appliance on which the VIP is active, because an ARP request with the VIP and a VMAC on that appliance has reached the upstream router. But in some cases, such as static routes configured on the upstream router for the VIP subnet, or a topology that blocks this route, the traffic can reach a NetScaler appliance on which the VIP is in backup state. If you want this appliance to forward the data packets to the appliance on which the VIP is active, you need to enable the send to master option. This behavior is a per node setting and is disabled by default.

For example, in the following diagram, VIP1 is configured on NS1, NS2, and NS3 and is active on NS1. Under certain circumstances, traffic for VIP1 (active on NS1) may reach VIP1 on NS3. When the send to master option is enabled on NS3, NS3 forwards the traffic to NS1 through NS2 by using route entries for NS1.

Figure 1. An Active-Active Configuration with Send to Master Option Enabled



To enable send to master by using the command line interface

At the command prompt, type:

set vrIDParam -sendToMaster (ENABLED | DISABLED)

Example

```
> set vrIDParam -sendToMaster ENABLED
 Done
```

To enable send to master by using the configuration utility

1. Navigate to System > Network, in the Settings group, click Virtual Router Parameters.
2. Select the Send to Master option.

Configuring VRRP Communication Intervals

Feb 13, 2017

In an active-active deployment, all NetScaler nodes use the Virtual Router Redundancy Protocol (VRRP) to advertise their master VIP addresses and the corresponding priorities in VRRP advertisement packets (hello messages) at regular intervals.

VRRP uses the following communication intervals:

- **Hello Interval**. Interval between the VRRP hello messages that a node of a master VIP address sends to its peer nodes.
- **Dead Interval**. Time after which a node of a backup VIP address considers the state of the master VIP address as DOWN if VRRP hello messages are not received from the node of the master VIP address. After the dead interval, the backup VIP address takes over and becomes the master VIP address.

You can change these intervals to a desired value. Both of these communication intervals are per node setting for all VIP addresses in that node.

To configure VRRP communication intervals by using the command line interface

At the command prompt, type:

set vrIDParam [-helloInterval <msecs>] [-deadInterval <secs>]

```
> set vrIDParam -helloInterval 500 -deadInterval 2
 Done
```

To configure VRRP communication intervals by using the configuration utility

1. Navigate to System > Network, in the Settings group, click Virtual Router Parameters.
2. Under Configure Virtual Router Parameter, set the Hello Interval and Dead Interval parameters.
3. Click OK.

Example 1: Nodes with the Same VRRP Dead Intervals

Consider an active-active deployment consisting of NetScaler ADCs NS1, NS2, and NS3. Virtual IP addresses VIP1, VIP2, VIP3 are configured on each of these ADCs. Because of their priorities, VIP1 is active on NS1, VIP2 is active on NS2, and VIP3 is active on NS3.

As shown in the table below, the dead interval is set to the same value (2 seconds) on all the three nodes.

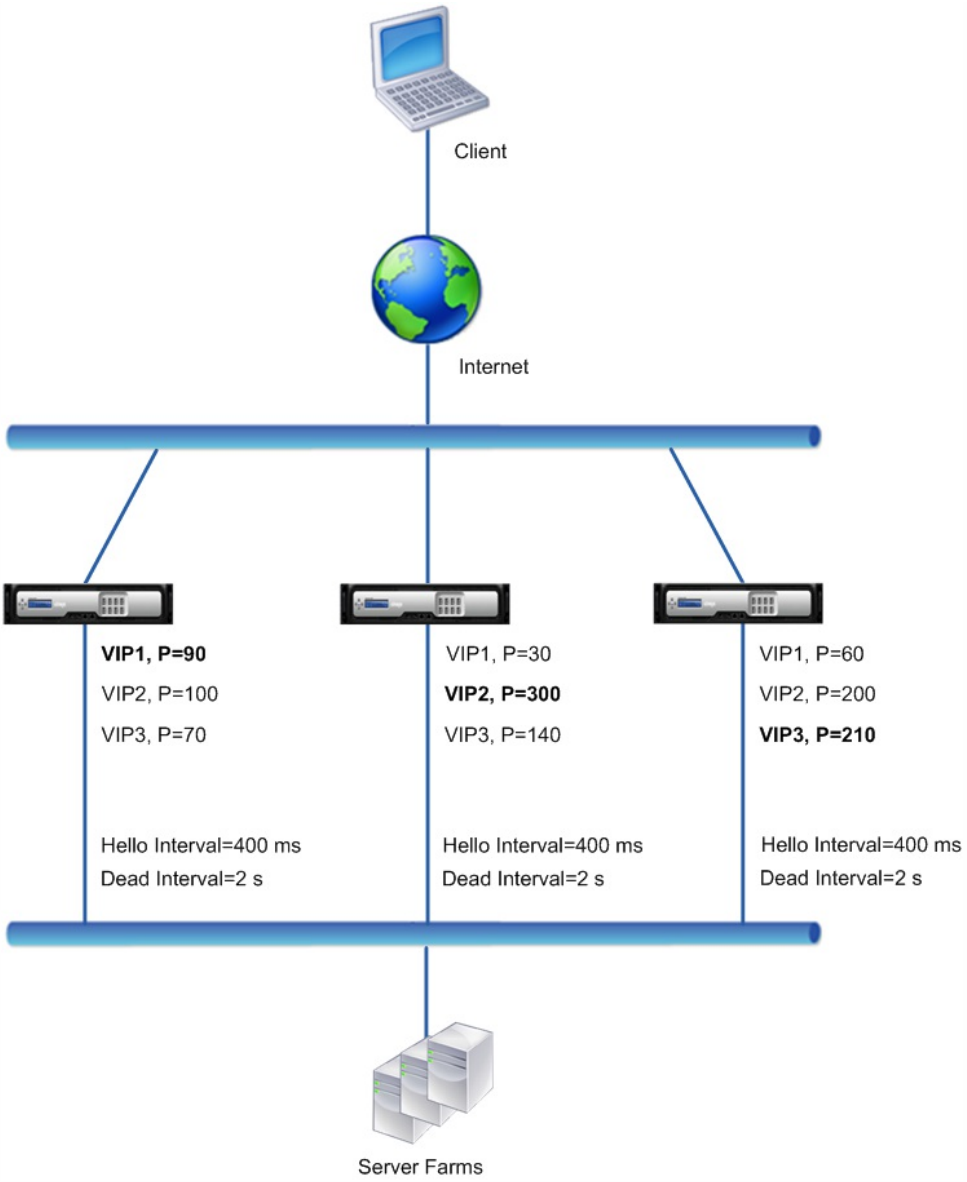
The VRRP communication intervals (hello interval and dead interval) of a node apply to all the VRIDs configured on the node, and in turn apply to all VIP addresses associated with the VRIDs on the node.

On each node, the VIP addresses that are active (master) on that node use the hello interval, and the dead interval is used by the VIP addresses that are inactive (backup) on that node.

Preemption is disabled for the VIP addresses in all the three nodes.

The following table lists the settings used in this example.

	Settings on NS1	Settings on NS2	Settings on NS3
VIP addresses			
VIP1 (for reference purposes only)	• IP address: 192.0.1.10 • VRID: 10 • Priority: 90	• IP address: 192.0.1.10 • VRID: 11 • Priority: 30	• IP address: 192.0.1.10 • VRID: 15 • Priority: 60
VIP2 (for reference purposes only)	• IP address: 192.0.1.20 • VRID: 20 • Priority: 100	• IP address: 192.0.1.20 • VRID: 21 • Priority: 300	• IP address: 192.0.1.20 • VRID: 25 • Priority: 200
VIP3 (for reference purposes only)	• IP address: 192.0.1.30 • VRID: 30 • Priority: 70	• IP address: 192.0.1.30 • VRID: 31 • Priority: 140	• IP address: 192.0.1.30 • VRID: 35 • Priority: 210
Communication Intervals			
Hello Interval	400 milliseconds	400 milliseconds	400 milliseconds
Dead Interval	2 seconds	2 seconds	2 seconds



The execution flow is as follows:

1. NS1 sends hello messages at a set hello interval of 400 ms to NS2 and NS3 for the VIP1 address, because VIP1 is active (the master) on NS1. Similarly, NS2 sends hello messages for VIP2, and NS3 sends hello messages for VIP3.
2. On NS1, the set dead interval applies to VIP2 and VIP3, because they are inactive (backups) on NS1. Similarly, on NS2, the set dead interval applies to VIP1 and VIP3, and on NS3, the set dead interval applies to VIP1 and VIP2.
3. If NS1 goes down, NS2 and NS3 consider NS1 to be down if they receive no hello messages from NS1 for 2 seconds (the dead interval). VIP1 on NS3 takes over and becomes active (master), because its VRID priority (60) is higher than that of VIP1 of NS2 (30).

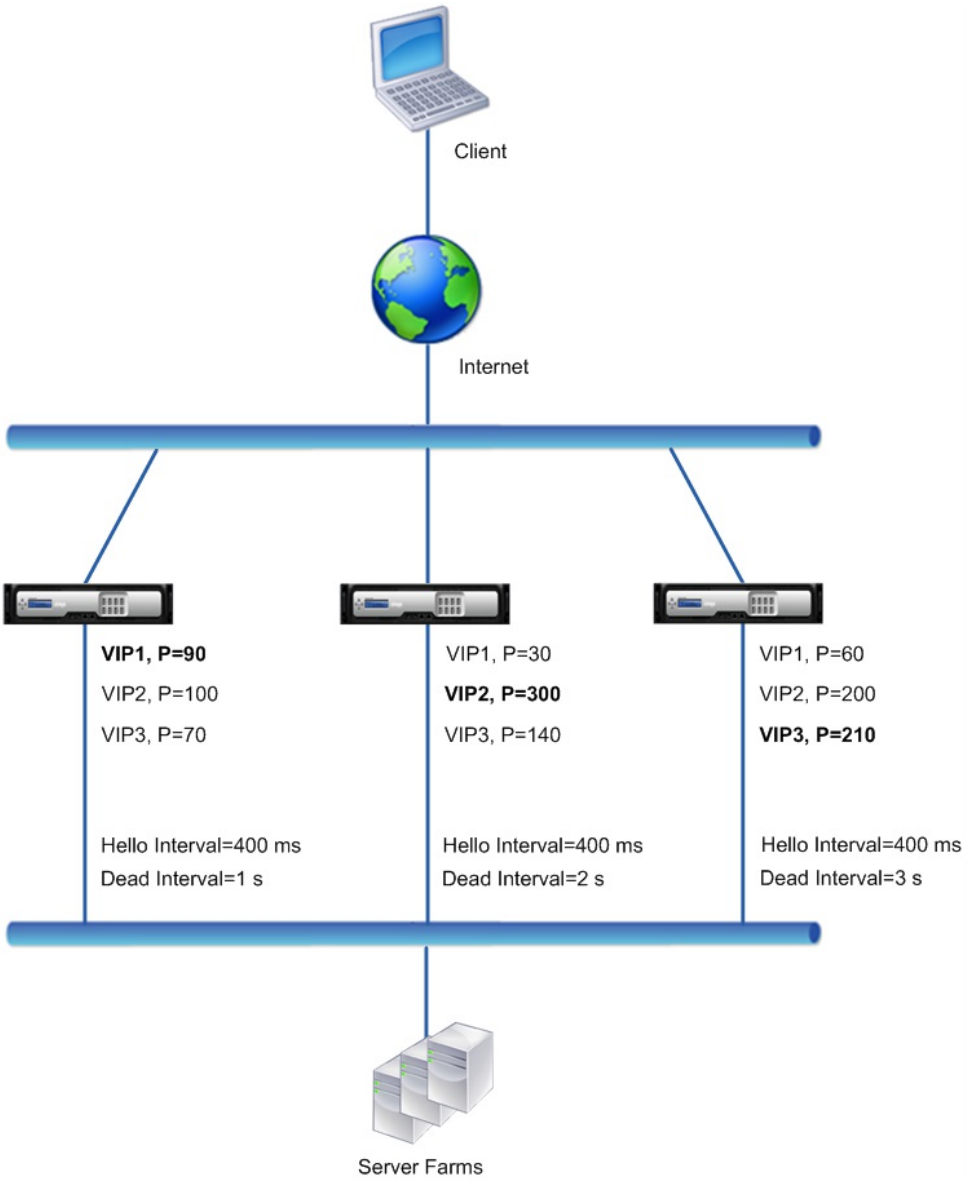
Example 2: Nodes with Different VRRP Dead Intervals

Consider a VRRP deployment similar to the deployment described in Example1 but with a different dead interval on each node (NS1, NS2, and NS3). Preemption is disabled for the VIP addresses in all the three nodes.

The following table lists the settings used in this example.

	Settings on NS1	Settings on NS2	Settings on NS3

VIP addresses			
VIP1 (for reference purposes only)	• IP address: 192.0.1.10 • VRID: 10 • Priority: 90	• IP address: 192.0.1.10 • VRID: 11 • Priority: 30	• IP address: 192.0.1.10 • VRID: 15 • Priority: 60
VIP2 (for reference purposes only)	• IP address: 192.0.1.20 • VRID: 20 • Priority: 100	• IP address: 192.0.1.20 • VRID: 21 • Priority: 300	• IP address: 192.0.1.20 • VRID: 25 • Priority: 200
VIP3 (for reference purposes only)	• IP address: 192.0.1.30 • VRID: 30 • Priority: 70	• IP address: 192.0.1.30 • VRID: 31 • Priority: 140	• IP address: 192.0.1.30 • VRID: 35 • Priority: 210
Communication Intervals			
Hello Interval	400 milliseconds	400 milliseconds	400 milliseconds
Dead Interval	1 second	2 seconds	3 seconds



The execution flow is as follows when NS1 goes down:

1. NS2 considers NS1 to be down after not receiving any hello messages from NS1 for 2 seconds (NS2's dead interval).
2. VIP1 on NS2 takes over and becomes active (master). NS2 now starts sending hello messages for VIP1.

Even though VIP1 on NS3 has a higher VRIP priority (60) than does VIP1 on NS2 (30), NS3's larger dead interval (3 seconds, vs. 2 seconds for NS2), prevents VIP1 on NS3 from taking over before VIP 1 on NS2 has already done so.

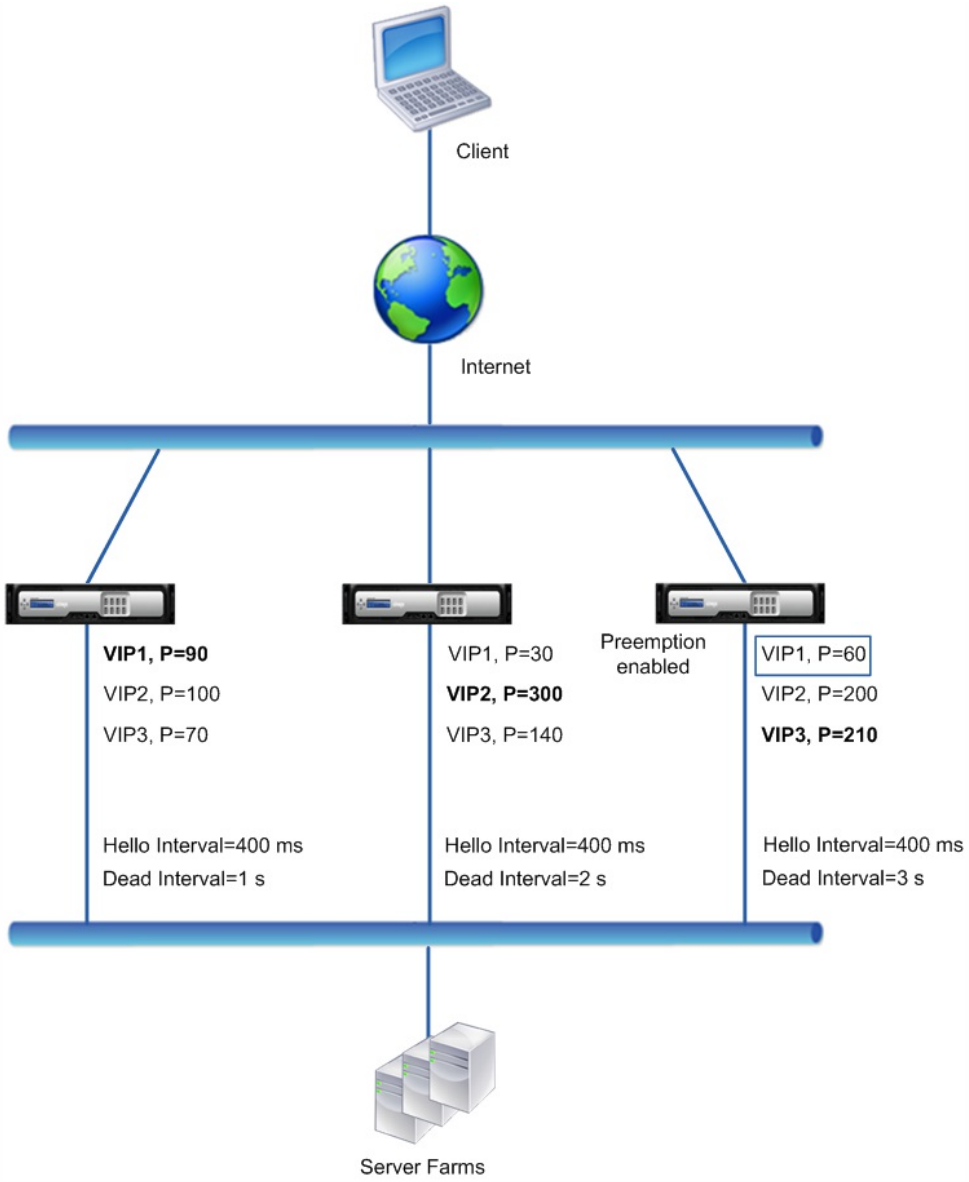
Example 3: Nodes with Different Dead Intervals and Preemption Enabled

Consider a VRRP deployment similar to the deployment described in Example1 but with different dead intervals on the three nodes, NS1, NS2, and NS3, and with preemption enabled for the VIP1 address on NS3.

The following table lists the settings used in this example.

	Settings on NS1	Settings on NS2	Settings on NS3
VIP addresses			

VIP1 (for reference purposes only)	• IP address: 192.0.1.10 • VRID: 10 • Priority: 90	• IP address: 192.0.1.10 • VRID: 11 • Priority: 30	• IP address: 192.0.1.10 • VRID: 15 • Priority: 60
VIP2 (for reference purposes only)	• IP address: 192.0.1.20 • VRID: 20 • Priority: 100	• IP address: 192.0.1.20 • VRID: 21 • Priority: 300	• IP address: 192.0.1.20 • VRID: 25 • Priority: 200
VIP3 (for reference purposes only)	• IP address: 192.0.1.30 • VRID: 30 • Priority: 70	• IP address: 192.0.1.30 • VRID: 31 • Priority: 140	• IP address: 192.0.1.30 • VRID: 35 • Priority: 210
Communication Intervals			
Hello Interval	400 milliseconds	400 milliseconds	400 milliseconds
Dead Interval	1 second	2 seconds	3 seconds



The execution flow is as follows when NS1 goes down:

1. NS2 considers NS1 to down after not receiving any hello messages from NS1 for 2 seconds (NS2's set dead interval). At this time, NS3, with a dead interval of 3 seconds, does not consider NS1 to be down.
2. VIP1 on NS2 takes over and becomes active (master). NS2 now starts sending hello messages for VIP1.
3. Upon receiving hello messages from NS2 for VIP1, NS3 preempts NS2 for VIP1 because preemption is enabled for VIP1 of NS3 and the VRID priority (60) of VIP1 of NS3 is higher than that (30) of VIP1 of NS2.
4. VIP1 on NS3 takes over and becomes active (master). NS3 now starts sending hello messages for VIP1.

Configuring Health Tracking based on Interface State

Jul 04, 2016

To ensure that a backup VIP address takes over as the master VIP before the node of the current master VIP address goes down completely, you can configure a node to change the priority of a VIP address when the state of an interface on the node changes. For example, the node reduces the priority of a VIP address when the state of an interface changes to DOWN, and increases the priority when the state of the interface changes to UP.
This feature is a per node configuration for each VIP address.

Example

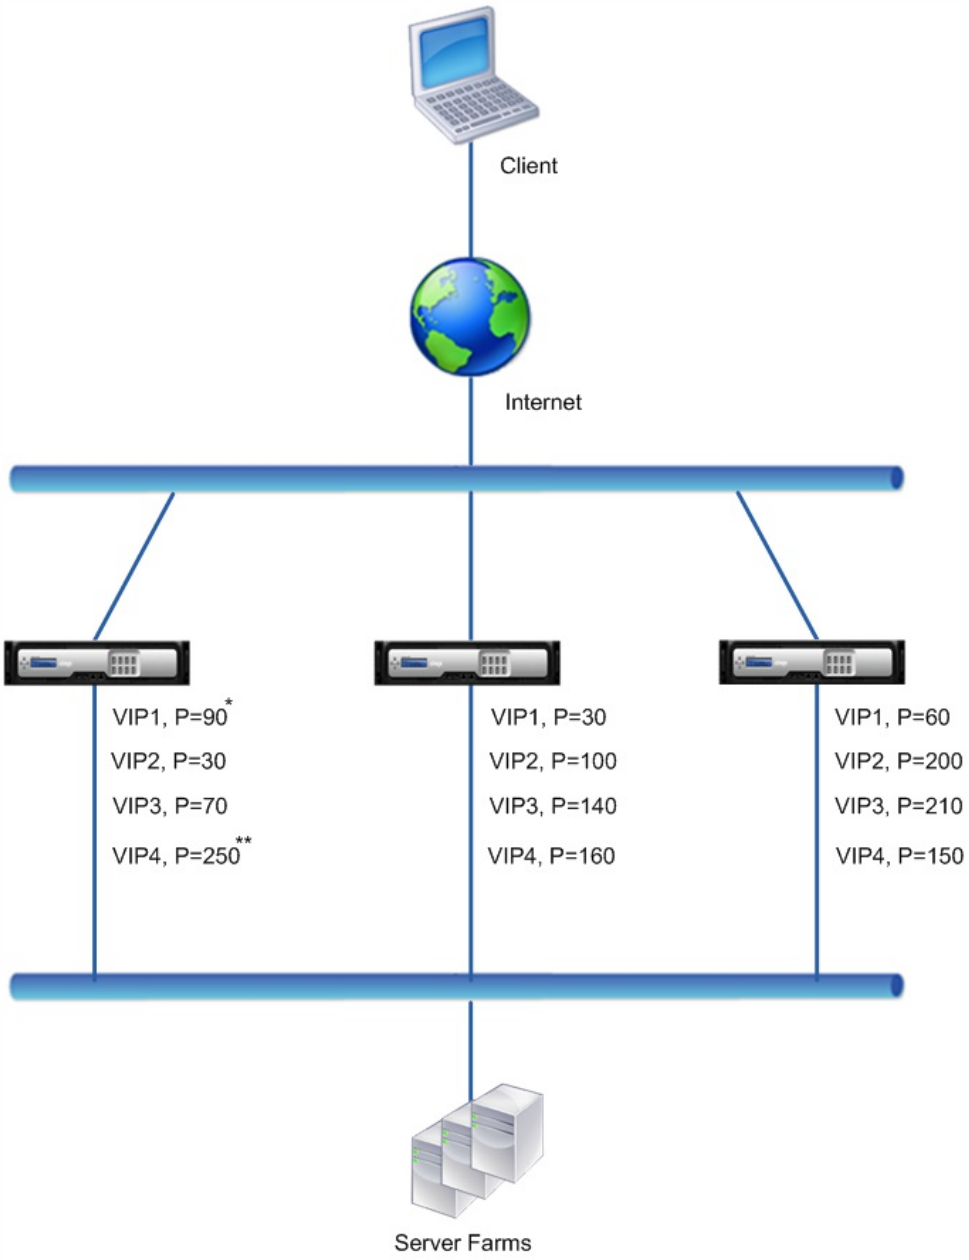
Consider an active-active deployment consisting of NetScaler ADCs NS1, NS2, and NS3. Virtual IP addresses VIP1, VIP2, VIP3, and VIP4 are configured on each of these ADCs. Because of their priorities, VIP1 and VIP4 are active on NS1, VIP2 is active on NS2, and VIP3 is active on NS3.

To ensure that the active VIP addresses on NS1 are taken over by either NS2 or NS3 before NS1 goes down completely, interface-based health tracking is configured for the VIP1 and VIP4 addresses on NS1. Configuring interface-based health tracking for a VIP address includes associating the desired interfaces and setting the reduced priority (trackifNumPriority) parameter for the associated VRID of the VIP address. For example, on NS1, interfaces 1/2, 1/3, and 1/5 are associated to the VRID of VIP1, and reduced priority is set to 20.

Preemption is enabled for these VIP addresses in all three nodes.

The following table lists the settings used in this example.

	Settings on NS1	Settings on NS2	Settings on NS3
VIP addresses			
VIP1 (for reference purposes only)	• IP address: 192.0.1.10 • VRID: 10 • Priority: 90	• IP address: 192.0.1.10 • VRID: 11 • Priority: 30	• IP address: 192.0.1.10 • VRID: 15 • Priority: 60
VIP2 (for reference purposes only)	• IP address: 192.0.1.20 • VRID: 20 • Priority: 100	• IP address: 192.0.1.20 • VRID: 21 • Priority: 300	• IP address: 192.0.1.20 • VRID: 25 • Priority: 200
VIP3 (for reference purposes only)	• IP address: 192.0.1.30 • VRID: 30 • Priority: 70	• IP address: 192.0.1.30 • VRID: 31 • Priority: 140	• IP address: 192.0.1.30 • VRID: 35 • Priority: 210
VIP4 (for reference purposes only)	• IP address: 192.0.1.40 • VRID: 40 • Priority: 250 • Track interfaces: 1/5, 1/7 • Reduced priority: 55	• IP address: 192.0.1.40 • VRID: 41 • Priority: 160	• IP address: 192.0.1.40 • VRID: 45 • Priority: 150



* Packet Interfaces = 1/2, 1/3, 1/5
Reduced Priority = 20

** Packet Interfaces = 1/5, 1/7
Reduced Priority = 55

The execution flow is as follows on NS1 when multiple interface on NS1 goes down:

1. If interface 1/3 goes down, the priority of address VIP1 is reduced by 20 (VIP1's reduced priority value), because interface 1/3 is associated with VIP1:
   - Effective priority of VIP1 = (Current priority - reduced priority) = (90-20) = 70
2. Similarly, if interface 1/5 goes down, the priority of address VIP1 is further reduced:
   - Effective priority of VIP1 = (Current priority - reduced priority) = (70-20) = 50
3. At this point, the effective priority of VIP1 on NS1 is less than the priority of VIP1 on NS3. NS3 preempts NS1 for VIP1. VIP1 on NS3 takes over and becomes active (master).
4. Also, because interface 1/5 is also associated with VIP4, the priority of VIP4 is reduced by the VIP4's reduced priority

value (55).
   - Effective priority of VIP4 = (250 - 55) = 195
5. If interface 1/7 goes down, the priority of VIP4 is further reduced:
   - Effective priority of VIP4 = (Current priority - reduced priority) = (195-55) = 145
6. At this point, the effective priority of VIP4 on NS1 is less than the priority of VIP4 on NS2. NS2 preempts NS1 for VIP4. VIP4 on NS3 takes over and becomes active (master). This configuration ensures that none of the four VIP addresses are active on NS1 before it completely goes down.

To configure this feature on a node for a VIP address, you set the Reduced Priority (trackifNumPriority) parameter, and then associate the interfaces whose state is to be tracked for changing the priority of the VIP address. When any of the associated interface's state changes to DOWN or UP, the node reduces or increases the priority of the VIP address by the configured Reduced Priority (trackifNumPriority) value.

To set reduced priority and bind interfaces to the virtual router ID by using the command line interface

At the command prompt, type:

- **set vrID** <id> [**-trackifNumPriority** <positive_integer>]
- **bind vrID** <id> **-trackifNum** <interface_name>
- **show vrID** <id>

To set reduced priority and bind interfaces to the virtual router ID by using the configuration utility

1. Navigate to **System** > **Network** > **VMAC**.
2. On the **VMACs** tab, select a virtual router ID, and click **Edit**.
3. Under **Configure VMAC**, set the **Reduced Priority** parameter.
4. Select the **Interfaces tracked for the VRID** option and, under **Associate Interfaces**, add interfaces to the virtual router ID.

```
> set vrID 125 -trackifNumPriority 10

Done

> bind vrID 125 -trackifNum 1/4 1/5

Done
```

To configure this feature on a node for a VIP6 address, you set the Reduced Priority (trackifNumPriority) parameter, and then associate the interfaces whose state is to be tracked for changing the priority of the VIP6 address. When any of the associated interface's state changes to DOWN or UP, the node reduces or increases the priority of the VIP6 address by the configured Reduced Priority (trackifNumPriority) value.

To change the priority of a VIP address automatically by using the command line interface

At the command prompt, type one of the following sets of commands.

If adding a new VMAC6:

- **add vrID6** <id> [**-trackifNumPriority** <positive_integer>]
- **bind vrID6** <id> **-trackifNum** <interface_name>
- **show vrID6** <id>

If reconfiguring an existing VMAC6:

- **set vrID6** <id> [**-trackifNumPriority** <positive_integer>]
- **bind vrID6** <id> **-trackifNum** <interface_name>
- **show vrID6** <id>

```
> set vrID6 130 -trackifNumPriority 10

Done

> bind vrID6 130 -trackifNum 1/4 1/5

Done
```

Delaying Preemption

Feb 13, 2017

By default, a backup VIP address preempts the master VIP address immediately after its priority becomes higher than that of the master VIP. When configuring a backup VIP address, you can specify an amount of time by which to delay the preemption. Preemption delay time is a per-node setting for each backup VIP address.

The preemption delay setting for a backup VIP does not apply in the following conditions:

- The node of the master VIP goes down. In this case, the backup VIP takes over as the master VIP after the dead interval set on the backup VIP's node.
- The priority of the master VIP is set to zero. The backup VIP takes over as the master VIP after the dead interval set on the backup VIP's node.

Consider an active-active deployment consisting of NetScaler appliances NS1 and NS2. Virtual IP address VIP1 is configured on each of these appliances. Because of their priorities, VIP1 is master on NS2. Preemption is enabled and preemption delay time is set for VIP1 on these two nodes.

The following table lists the settings used in this example.

	Settings on NS1	Settings on NS2
VIP1 (for reference purposes only)	· IP address: 192.0.1.10 · VRID: 10 · Priority: 100 · Preemption: Enabled · Preemption delay time: 1000 seconds	· IP address: 192.0.1.10 · VRID: 10 · Priority: 200 · Preemption: Enabled · Preemption delay time: 2000 seconds
Dead Interval	1 Seconds	2 Seconds

Following are some examples of possible preemption behavior in this setup:

- If the priority of VIP1 on NS1 is set to a value (for example, 210) higher than that of VIP1 on NS2, VIP1 on NS1 takes over as master after its set preemption delay time (1000 secs).
- If a third node NS3 with the following VRRP settings is added to this deployment, VIP1 on NS3 becomes master after its set preemption delay time (3000 secs).

- VIP1
  - VRID: 30
  - IP address:
  - Priority = 300
  - Preemption delay time = 3000 seconds
- If NS2 goes down, VIP1 on NS1 takes over as master after 1 second (set dead interval on NS1). Preemption delay time for VIP1 on NS1 does not apply in this case.
- If NS2 goes down and NS1 restarts, VIP1 on NS1 becomes master 1 second (set dead interval on NS1) after NS1 comes up. Preemption delay time for VIP1 on NS1 does not apply in this case.
- If the priority of VIP1 on NS2 is set to zero, VIP1 goes to standby mode. VIP1 on NS1 takes over as master after 1 second (set dead interval on NS1). Preemption delay time for VIP1 on NS1 does not apply in this case.

To configure preemption delay time for a VIP address, you set the preemption delay timer parameter of the associated VMAC address. You can the set this parameter when you add the address, or you can modify an existing VMAC address.

To configure preemption delay time by using the NetScaler command line

- To set the preemption delay time while adding a VMAC, at the command prompt, type:
  - **add vrID** <id> -**preemptiondelaytimer** <secs>
  - **show vrID**

- To set the preemption delay time while modifying a VMAC, at the command prompt, type:
  - **set vrID** <id> -**preemptiondelaytimer** <secs>
  - **show vrID**

To configure preemption delay time by using the configuration utility

1. Navigate to **System** > **Network** > **VMAC**.
2. On the **VMAC** tab. While adding a new VMAC, or editing an existing VMAC, set the **Preemption Delay Timer** parameter.

The following configuration uses the settings listed in table in section Example: Delaying Preemption.

Settings on NS1

> set vrid param –deadInterval 1

Done

> add ns ip 192.0.1.10 255.255.255.255 –type VIP

```
Done

> add vrid 10 –Priority 100 –Preemption Enable –preemptiondelaytimer 1000

Done

> bind ns ip 192.0.1.10 255.255.255.255 –vrid 10

Done

Settings on NS2

> set vrid param –deadInterval 2

Done

> add ns ip 192.0.1.10 255.255.255.255 –type VIP

Done

> add vrid 20 –Priority 200 –Preemption Enable –preemptiondelaytimer 2000

Done

> set ns ip 192.0.1.10 255.255.255.255 –vrid 10

Done
```

To configure preemption delay time for a VIP6 address, you set the preemption delay timer parameter of the associated VMAC6 address. You can the set this parameter when you add the VMAC6 address, or you can modify an existing VMAC6 address.

To configure preemption delay time by using the NetScaler command line

- To set the preemption delay time while adding a VMAC6, at the command prompt, type:
  - add vrID6 <id> -preemptiondelaytimer <secs>
  - show vrID6
- To set the preemption delay time while modifying a VMAC6, at the command prompt, type:
  - set vrID6 <id> -preemptiondelaytimer <secs>
  - show vrID6

To configure preemption delay time by using the configuration utility

1. Navigate to System > Network > VMAC.
2. On the VMAC6 tab. While adding a VMAC6 address, or editing an existing VMAC6 address, set the Preemption Delay Timer parameter.

Keeping a VIP Address in the Backup State

Jul 04, 2016

You can force a VIP address to always stay in backup state. This operation is helpful in maintenance or testing of a VRRP deployment.

When a VIP address is forced to stay in backup state, it does not participate in VRRP state transitions. Also, it cannot become master even if all other nodes go down.

To force a VIP address to stay in backup state, you set the priority of the associated VMAC address to zero. To ensure that none of the VIP addresses of a node handle traffic during a maintenance process on the node, set all the priorities to zero.

You can the set the priority of a VMAC address while adding or modifying the address.

To force a VIP address to stay in the backup state by using the NetScaler command line

- To set the priority while adding a VMAC, at the command prompt, type:
  - **add vrID** <id> **-priority** 0
  - **show vrID**
- To set the priority while modifying a VMAC, at the command prompt, type:
  - **set vrID** <id> **-priority** 0
  - **show vrID**

To force a VIP address to stay in backup state by using the configuration utility

1. Navigate to **System** > **Network** > **VMAC**.
2. On the **VMAC** tab, while adding a new VMAC or editing an existing VMAC, set the **Priority** parameter to zero.

Using the Network Visualizer

Aug 29, 2013

The network visualizer shows a graphical view of all the interfaces, channels, VLANs, IP addresses, and bindings to VLANs on a NetScaler appliance. An enabled interface or channel has a black label. A disabled interface or channel has a red label.

This complete picture of the appliance's network connections can be useful for detecting flaws in the network design and for optimizing the network. It can also help a new administrator easily understand the appliance's network configuration.

To open the Network Visualizer

Navigate to **System** > **Network**. In **Monitor Connections**, click **Network Visualizer**.

Configuring Link Layer Discovery Protocol

Dec 29, 2016

The NetScaler ADC supports the industry standard (EEE 802.1AB) Link Layer Discovery Protocol (LLDP). LLDP is a layer 2 protocol that enables the NetScaler ADC to advertise its identity and capabilities to the directly connected devices, and also learn the identity and capabilities of these neighbour devices. Using LLDP, the NetScaler ADC transmits and receives information in the form of LLDP messages known as LLDP packet data units (LLDPUs).

An LLDPU is a sequence of type, length, value (TLV) information elements. Each TLV holds a specific type of information about the device that transmits the LLDPDU. The NetScaler ADC sends the following TLVs in each LLDPU:

- Chassis ID
- Port ID
- Time-to-live value
- System name
- System description
- Port description
- System capabilities
- Management address
- Port VLAN ID
- Link aggregation

Note: You cannot specify the TLVs to be sent in LLDP messages.
NetScaler interfaces support the following LLDP modes:

- **NONE**. The interface neither receives from nor transmits LLDP messages to the directly connected device.
- **TRANSMITTER**. The interface transmits LLDP messages to the directly connected device but does not receive LLPD messages from the directly connected device.
- **RECEIVER**. The interface receives LLDP messages from the directly connected device but does transmit LLPD messages to the directly connected device.
- **TRANSCEIVER**. The interface transmits LLDP messages to and receives LLDP messages from the directly connected device.

The LLDP mode of an interface depends on the LLDP mode configured at the global and the interface levels. The following table shows the modes resulting from the available combinations of global- and interface-level settings:

Interface Level LLDP mode	Global Level LLDP mode			
	NONE	TRANSMITTER	RECEIVER	TRANSCEIVER
NONE	NONE	NONE	NONE	NONE
TRANSMITTER	NONE	TRANSMITTER	NONE	TRANSMITTER
RECEIVER	NONE	NONE	RECEIVER	RECEIVER
TRANSCEIVER	NONE	TRANSMITTER	RECEIVER	TRANSCEIVER

Transmitting LLDP messages

The NetScaler ADC transmits LLDPUs from interfaces that are operating in either TRANSMITTER or TRANSCEIVER LLDP mode.

Following are the global LLDP transmitting parameters on the NetScaler ADC:

- **Timer**. Interval, in seconds, between LLDPUs that the NetScaler ADC sends to a directly connected device.
- **Holdtime Multiplier**. A multiplier for calculating the duration for which the receiving device stores the LLDP information in its database before discarding or removing it. The duration is calculated as the **Holdtime Multiplier** parameter value multiplied by the Timer parameter value.

Receiving LLDP Messages

The NetScaler ADC stores the LLDPDU information in its Management Information base (MIB). The stored LLDP information is classified or grouped under the ID of the interface that received the LLDPDU. The NetScaler ADC retains this LLDP information for the duration specified in the received LLDPU.

If the ADC receives another LLDPDU on an interface before the stored LLDP information for that interface is discarded, the ADC replaces the stored LLDP information for that interface with information in the new LLDPDU.

Configuration Steps

Configuring LLDP on a NetScaler appliance consists of the following tasks:

1. Set global level LLDP parameters. In this task, you set the global LLDP parameters such as LLDP Timer, Hold Time Multiplier, and LLDP mode.
2. Set the interface level LLDP parameters. In this task, you set the LLDP mode for an interface.
3. (Optional) Display neighbor-device information. You can display the neighbor-device LLDP information collected on all of the NetScaler ADC's interfaces, or just the LLDP information collected on specified interfaces. If you do not specify an interface, the information is shown for all interfaces.

Following are the prerequisites for configuring LLDP on a NetScaler ADC:

1. Make sure that you understand the standard LLDP protocol (IEEE 802.1AB).
2. Verify that you have configured LLDP on the desired directly connected devices.

To set global level LLDP parameters by using the command line interface

At the command prompt, type:

- set lldp param [-[-holdtimeTxMult <positive_integer>][-timer <positive_integer>] [-Mode <Mode>]
- show lldp param

To set the global level LLDP parameters by using configuration utility

1. Navigate to System > Network, and click Configure LLDP Parameters.
2. Set the following parameters:
   - Hold Timer Multiplier
   - Timer
   - Mode

To configure an interface for LLDP by using the command line interface

At the command prompt, type:

- set interface <id> -lldpmode <lldpmode>
- show interface <id>

To configure an interface for LLDP by using configuration utility

Navigate to System > Network > Interfaces, open the interface, and set the LLDP mode parameter.

To display neighbor device information by using the command line interface

At the command prompt, type one of the following commands:

- show lldp neighbors
- show lldp neighbors <ifnum>

To display neighbor device information by using configuration utility

Navigate to System > Network > Interfaces and, in the Action list, select View LLDP Neighbors.

LLDP Support in a Cluster Setup

In a cluster setup, the NetScaler GUI and NetScaler CLI display the LLDP neighbour configuration of all or specific cluster nodes when the GUI or CLI is accessed through the Cluster IP address (CLIP). Any change made to the global level LLDP mode is applied to the global level LLDP mode on each of the cluster nodes.

Consider an example of a cluster setup of three nodes, NS1, NS2, and NS3. Each of these nodes are connected to both routers Router-1 and Router-2. The following output is displayed when the **show lldp neighbor -summary** operation is performed on the Cluster CLI that is accessed through the Cluster IP address (CLIP) of the cluster setup. The output shows the LLDP neighbour information of all these nodes.

```
> show lldp neighbor -summary

Node Id: 1

-------------------------------------------------------------------------------

    Interface   ChassisId          PortId    System name

-------------------------------------------------------------------------------

1    1/1/1      fe:c7:3b:13:bd:11   1/1       Router-1

2    1/1/2      12:68:7b:9e:4c:11   1/1       Router-2

Node Id: 2
```

```
-------------------------------------------------------------------------------
    Interface    ChassisId          PortId     System name

Done
```

Jumbo Frames

Feb 13, 2017

NetScaler appliances support receiving and transmitting jumbo frames containing up to 9216 bytes of IP data. Jumbo frames can transfer large files more efficiently than it is possible with the standard IP MTU size of 1500 bytes.

A NetScaler appliance can use jumbo frames in the following deployment scenarios:

- Jumbo to Jumbo. The appliance receives data as jumbo frames and sends it as jumbo frames.
- Non-Jumbo to Jumbo. The appliance receives data as regular frames and sends it as jumbo frames.
- Jumbo to Non-Jumbo. The appliance receives data as jumbo frames and sends it as regular frames.

The NetScaler appliance supports jumbo frames in a load balancing configuration for the following protocols:

- TCP
- Any protocol over TCP (for example, HTTP)
- SIP
- RADIUS

This document includes the following information:

Configuring Jumbo Frames Support on a NetScaler Appliance

Apr 10, 2014

To enable the NetScaler appliance to support jumbo frames, you set the MTU to more than 1500 on interfaces or LA channels, and on VLANs on which you want the NetScaler appliance to support jumbo frames.

Points to consider before setting the MTU of interfaces, LA channels, or VLANs on a NetScaler appliance

1. Jumbo frames are not supported on NetScaler MPX 15000 and MPX 17000 Platforms.
2. When you create an LA channel, the channel takes the MTU of the first bound interface if no MTU is specified for the channel.
3. The MTU for a channel is propagated to all the bound interfaces.
4. When an interface is bound to the channel whose MTU is different from the interface's MTU, the interface goes onto the inactive list.
5. When you change the MTU of a member interface, the interface goes onto the inactive list.
6. When an interface is unbound from the channel, the interface retains the MTU value of the channel.
7. You can set the MTU for an interface, channel, or VLAN to a value in the range of 1500-9216.
8. You cannot set the MTU on the default VLAN. The NetScaler appliance uses the MTU of the interface through which it receives or sends data from or to the default VLAN.
9. For TCP based traffic on a load balancing configuration on a NetScaler appliance, MSSs are set accordingly at each end point for supporting jumbo frames:
   - For a connection between a client and a load balancing virtual server on the NetScaler appliance, the MSS on the NetScaler appliance is set in a TCP profile, which is then bound to the load balancing virtual server.
   - For a connection between the NetScaler appliance and a server, the MSS on NS1 is set in a TCP profile, which is then bound to the service representing the server on the NetScaler appliance.
   - By default, a TCP profile nstcp_default_profile is bound to all TCP based load balancing servers and services on the NetScaler appliance.
   - For supporting jumbo frames, you can either change the MSS value of the TCP profile nstcp_default_profile, or create a custom TCP profile and set its MSS accordingly, and then bind the custom TCP profile to the desired load balancing virtual servers and services.
   - The default MSS value of any TCP profile is 1460.

To set the MTU of an interface by using the command line interface

At the command prompt, type:

- set interface <id> -mtu <positive_integer>
- show interface <id>

Example

```
> set interface 10/1 –mtu 9000
Done
```

To set the MTU of a channel by using the command line interface

At the command prompt, type:

- set channel <id> -mtu <positive_integer>

- show channel <id>

Example

```
> set channel LA/1 –mtu 9000
Done
```

To set the MTU of a VLAN by using the command line interface

At the command prompt, type:

- add vlan <id> -mtu <positive_integer>
- show vlan <id>

Example

```
> set vlan 20 –mtu 9000
Done
```

To set the MTU of an interface by using the configuration utility

Navigate to System > Network > Interfaces, open the interface, and set the Maximum Transmission Unit parameter.

To set the MTU of a channel by using the configuration utility

Navigate to System > Network > Channels, open the channel, and set the Maximum Transmission Unit parameter.

To set the MTU of a VLAN by using the configuration utility

Navigate to System > Network > VLANs, open the VLAN, and set the Maximum Transmission Unit parameter.

Use Case 1 – Jumbo to Jumbo Setup

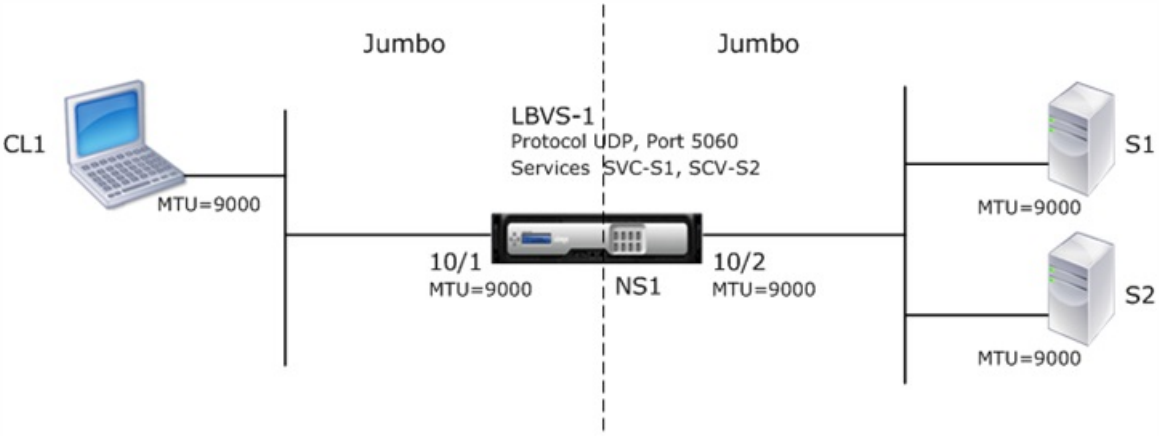
May 06, 2014

Consider an example of a jumbo to jumbo setup in which SIP load balancing virtual server LBVS-1, configured on NetScaler appliance NS1, is used to load balance SIP traffic across servers S1 and S2. The connection between client CL1 and NS1, and the connection between NS1 and the servers support jumbo frames.

Interface 10/1 of NS1 receives or sends traffic from or to client CL1. Interface 10/2 of NS1 receives or sends traffic from or to server S1 or S2. Interfaces 10/1 and 10/2 of NS1 are part of VLAN 10 and VLAN 20, respectively.

For supporting jumbo frames, the MTU is set to 9216, on NS1, for interfaces 10/1, 10/2, and VLANs VLAN 10, VLAN 20.

All other network devices, including CL1, S1, S2, in this setup example are also configured for supporting jumbo frames.



The following table lists the settings used in the example.

Entity	Name	Details
IP address of client CL1		192.0.2.10
IP address of servers	S1	198.51.100.19
	S2	198.51.100.20
SNIP address on NS1		198.51.100.18
MTU specified for interfaces and VLANs on NS1	10/1	9000
	10/2	9000
	VLAN 10	9000
	VLAN 20	9000
Services on NS1 representing servers	SVC-S1	• IP address: 198.51.100.19 • Protocol: SIP • Port: 5060

Entity	Name	Details
	SVC-S2	• IP address: 198.51.100.20 • Protocol: SIP • Port: 5060
Load balancing virtual server on VLAN 10	LBVS-1	• IP address: 203.0.113.15 • Protocol: SIP • Port:5060 • Bound services: SVC-S1, SVC-S2

Following is the traffic flow of CL1's request to NS1:

1. CL1 creates a 20000-byte SIP request to send to LBVS-1 of NS1.
2. CL1 sends the request data in IP fragments to LBVS-1. The size of each IP fragment is either equal to or less than the MTU (9000) set on the interface from which CL1 sends these fragments to NS1.
   - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
   - Size of the second IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
   - Size of the last IP fragment=[IP header + SIP data segment] = [20 + 2048] = 2068
3. NS1 receives the request IP fragments at interface 10/1. NS1 accepts these fragments, because the size of each of these fragments is equal to or less than the MTU (9000) of interface 10/1.
4. NS1 reassembles these IP fragments to form the 20000-byte SIP request. NS1 processes this request.
5. LBVS-1's load balancing algorithm selects server S1.
6. NS1 sends the request data in IP fragments to S1. The size of each IP fragment is either equal or less than the MTU (9000) of the interface 10/2, from which NS1 sends these fragments to S1. The IP packets are sourced with a SNIP address of NS1.
   - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
   - Size of the second IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
   - Size of the last IP fragment=[IP header + SIP data segment] = [20 + 2048] = 2068

Following is the traffic flow of S1's response to CL1 in this example:

1. Server S1 creates a 30000-byte SIP response to send to the SNIP address of NS1.
2. S1 sends the response data in IP fragments to the SNIP address of NS1. The size of each IP fragment is either equal to or less than the MTU (9000) set on the interface from which S1 sends these fragments to NS1.
   - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
   - Size of the second and third IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
   - Size of the last IP fragment=[IP header + SIP data segment] = [20 + 3068] = 3088
3. NS1 receives the response IP fragments at interface 10/2. NS1 accepts these fragments, because the size of each fragment is equal to or less than the MTU (9000) of interface 10/2.
4. NS1 reassembles these IP fragments to form the 30000-byte SIP response. NS1 processes this response.
5. NS1 sends the response data in IP fragments to CL1. The size of each IP fragment is either equal or less than the MTU (9000) of the interface 10/1, from which NS1 sends these fragments to CL1. The IP fragments are sourced with LBVS-1's IP address.
   - Size of the first IP fragment = [IP header + UDP header + SIP data segment] = [20 + 8 + 8972] = 9000
   - Size of the second and third IP fragment = [IP header + SIP data segment] = [20 + 8980] = 9000
   - Size of the last IP fragment=[IP header + SIP data segment] = [20 + 3068] = 3088

Updated: 2014-01-16

The following table list the tasks, NetScaler commands, and examples for creating the required configuration on the NetScaler appliance.

Tasks	NetScaler Command Syntax	Examples
Set the MTU of the desired interfaces for supporting jumbo frames	set interface <id> -mtu <positive_integer> show interface <id>	set int 10/1 -mtu 9000 set int 10/2 -mtu 9000
Create VLANs and set the MTU of the desired VLANs for supporting jumbo frames	add vlan <id> -mtu <positive_integer> show vlan <id>	add vlan 10 -mtu 9000 add vlan 20 -mtu 9000
Bind interfaces to VLANs	bind vlan <id> -ifnum <interface_name> show vlan <id>	bind vlan 10 -ifnum 10/1 bind vlan 20 -ifnum 10/2
Add a SNIP address	add ns ip <IPAddress> <netmask> -type SNIP show ns ip	add ns ip 198.51.100.18 255.255.255.0 -type SNIP
Create services representing SIP servers	add service <serviceName> <ip> SIP_UDP <port> show service <name>	add service SVC-S1 198.51.100.19 SIP_UDP 5060 add service SVC-S2 198.51.100.20 SIP_UDP 5060
Create SIP load balancing virtual servers and bind the services to it	add lb vserver <name> SIP_UDP <ip> <port> bind lb vserver <vserverName> <serviceName> show lb vserver <name>	add lb vserver LBVS-1 SIP_UDP 203.0.113.15 5060 bind lb vserver LBVS-1 SVC-S1 bind lb vserver LBVS-1 SVC-S2
Save the configuration	save ns config show ns config	

1.

Use Case 2 – Non-Jumbo to Jumbo Setup

May 06, 2014

Consider an example of a regular to jumbo setup in which load balancing virtual server LBVS-1, configured on a NetScaler appliance NS1, is used to load balance traffic across servers S1 and S2. The connection between client CL1 and NS1 supports regular frames, and the connection between NS1 and the servers supports jumbo frames.

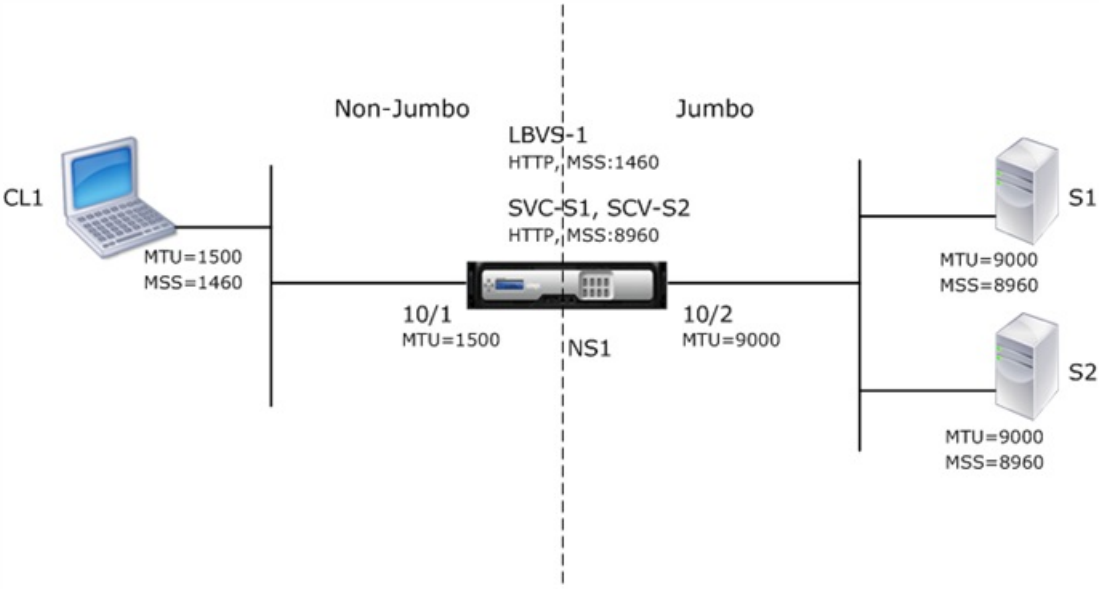
Interface 10/1 of NS1 receives or sends traffic from or to client CL1. Interface 10/2 of NS1 receives or sends traffic from or to server S1 or S2.

Interfaces 10/1 and 10/2 of NS1 are part of VLAN 10 and VLAN 20, respectively. For supporting only regular frames between CL1 and NS1, the MTU is set to the default value of 1500 for both interface 10/1 and VLAN 10

For supporting jumbo frames between NS1 and the servers, the MTU is set to 9000 for interface 10/2 and VLAN 20. Servers and all other network devices between NS1 and the servers are also configured for supporting jumbo frames.

Since HTTP traffic is based on TCP, MSSs are set accordingly at each end point for supporting jumbo frames.

- For supporting jumbo frames for the connection between a SNIP address of NS1 and S1 or S2, the MSS on NS1 is set accordingly in a custom TCP profile, which is bound to the services (SVC-S1 and SVC-S1) representing S1 and S2 on NS1.
- For supporting only regular frames for the connection between CL1 and virtual server LBVS-1 of NS1, default TCP profile nstcp_default_profile is used that is by default bound to LBVS-1 and has the MSS set to the default value of 1460.



The following table lists the settings used in this example.

Entity	Name	Details
IP address of client CL1	CL1	192.0.2.10
IP address of servers	S1	198.51.100.19
	S2	198.51.100.20
SNIP address on NS1		198.51.100.18

Entity	Name	Details
MTU specified for interfaces and VLANs on NS1	10/1	1500
	10/2	9000
	VLAN 10	1500
	VLAN 20	9000
Default TCP profile	nstcp_default_profile	MSS:1460
Custom TCP profile	NS1-SERVERS-JUMBO	MSS: 8960
Services on NS1 representing servers	SVC-S1	• IP address: 198.51.100.19 • Protocol: HTTP • Port: 80 • TCP profile: NS1-SERVERS-JUMBO (MSS: 8960)
	SVC-S2	• IP address: 198.51.100.20 • Protocol: HTTP • Port: 80 • TCP profile: NS1-SERVERS-JUMBO (MSS: 8960)
Load balancing virtual server on VLAN 10	LBVS-1	• IP address = 203.0.113.15 • Protocol: HTTP • Port:80 • Bound services: SVC-S1, SVC-S2 • TCP Profile: nstcp_default_profile (MSS:1460)

Following is the traffic flow of CL1's request to S1 in this example:

1. Client CL1 creates a 200-byte HTTP request to send to virtual server LBVS-1 of NS1.
2. CL1 opens a connection to LBVS-1 of NS1. CL1 and NS1 exchange their respective TCP MSS values while establishing the connection.
3. Because NS1's MSS is larger than the HTTP request, CL1 sends the request data in a single IP packet to NS1.
   Size of the request packet = [IP Header + TCP Header + TCP Request] = [20 + 20 + 200] = 240
4. NS1 receives the request packet at interface 10/1 and then processes the HTTP request data in the packet.
5. LBVS-1's load balancing algorithm selects server S1, and NS1 opens a connection between one of its SNIP addresses and S1. NS1 and CL1 exchange their respective TCP MSS values while establishing the connection.
6. Because S1's MSS is larger than the HTTP request, NS1 sends the request data in a single IP packet to S1.
   Size of the request packet = [IP Header + TCP Header + [TCP Request] = [20 + 20 + 200] = 240

Following is the traffic flow of S1's response to CL1 in this example:

1. Server S1 creates an 18000-byte HTTP response to send to the SNIP address of NS1.

2. S1 segments the response data into multiples of NS1's MSS and sends these segments in IP packets to NS1. These IP packets are sourced from S1's IP address and destined to the SNIP address of NS1.
   - Size of the first two packet = [IP Header + TCP Header + (TCP segment=NS1's MSS size)] = [20 + 20 + 8960] = 9000
   - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 2080] = 2120
3. NS1 receives the response packets at interface 10/2.
4. From these IP packets, NS1 assembles all the TCP segments to form the HTTP response data of 18000 bytes. NS1 processes this response.
5. NS1 segments the response data into multiples of CL1's MSS and sends these segments in IP packets, from interface 10/1, to CL1. These IP packets are sourced from LBVS-1's IP address and destined to CL1's IP address.
   - Size of all packets except the last one = [IP Header + TCP Header + (TCP payload=CL1's MSS size)] = [20 + 20 + 1460] = 1500
   - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 480] = 520

Updated: 2014-01-16

The following table list the tasks, NetScaler commands, and examples for creating the required configuration on the NetScaler appliance.

Tasks	NetScaler Command line Syntax	Examples
Set the MTU of the desired interfaces for supporting jumbo frames	set interface <id> -mtu <positive_integer> show interface <id>	set int 10/1 -mtu 1500 set int 10/2 -mtu 9000
Create VLANs and set the MTU of the desired VLANs for supporting jumbo frames	add vlan <id> -mtu <positive_integer> show vlan <id>	add vlan 10 -mtu 1500 add vlan 20 -mtu 9000
Bind interfaces to VLANs	bind vlan <id> -ifnum <interface_name> show vlan <id>	bind vlan 10 -ifnum 10/1 bind vlan 20 -ifnum 10/2
Add a SNIP address	add ns ip <IPAddress> <netmask> -type SNIP show ns ip	add ns ip 198.51.100.18 255.255.255.0 -type SNIP
Create services representing HTTP servers	add service <serviceName> <ip> HTTP <port> show service <name>	add service SVC-S1 198.51.100.19 http 80 add service SVC-S2 198.51.100.20 http 80
Create HTTP load balancing virtual servers and bind the services to it	add lb vserver <name> HTTP <ip> <port> bind lb vserver <vserverName> <serviceName> show lb vserver <name>	add lb vserver LBVS-1 http 203.0.113.15 80 bind lb vserver LBVS-1 SVC-S1 bind lb vserver LBVS-1 SVC-S2
Create a custom TCP profile and set its MSS for supporting jumbo frames	add tcpProfile <name> -mss <positive_integer> show tcpProfile <name>	add tcpprofile NS1-SERVERS-JUMBO -mss 8960
Bind the custom TCP profile to the desired services	set service <Name> -tcpProfileName <string> show service <name>	set service SVC-S1 -tcpProfileName NS1-SERVERS-JUMBO set service SVC-S2 -tcpProfileName NS1-SERVERS-JUMBO

Tasks	NetScaler Command line Syntax	Examples
Save the configuration	save ns config show ns config	

Use Case 3 – Coexistence of Jumbo and Non-Jumbo flows on the Same Set of Interfaces

May 06, 2014

Consider an example in which load balancing virtual servers LBVS-1 and LBVS-2 are configured on NetScaler appliance NS1. LBVS-1 is used to load balance HTTP traffic across servers S1 and S2, and LBVS-2 is used to load balance traffic across servers S3 and S4.

CL1 is on VLAN 10, S1 and S2 are on VLAN20, CL2 is on VLAN 30, and S3 and S4 are on VLAN 40. VLAN 10 and VLAN 20 support jumbo frames, and VLAN 30 and VLAN 40 support only regular frames.

In other words, the connection between CL1 and NS1, and the connection between NS1 and server S1 or S2 support jumbo frames. The connection between CL2 and NS1, and the connection between NS1 and server S3 or S4 support only regular frames.

Interface 10/1 of NS1 receives or sends traffic from or to clients. Interface 10/2 of NS1 receives or sends traffic from or to the servers.

Interface 10/1 is bound to both VLAN 10 and VLAN 30 as a tagged interface, and interface 10/2 is bound to both VLAN 20 and VLAN 40 as a tagged interface.

For supporting jumbo frames, the MTU is set to 9216 for interfaces 10/1 and 10/2.

On NS1, the MTU is set to 9000 for VLAN 10 and VLAN 20 for supporting jumbo frames, and the MTU is set to the default value of 1500 for VLAN 30 and VLAN 40 for supporting only regular frames.

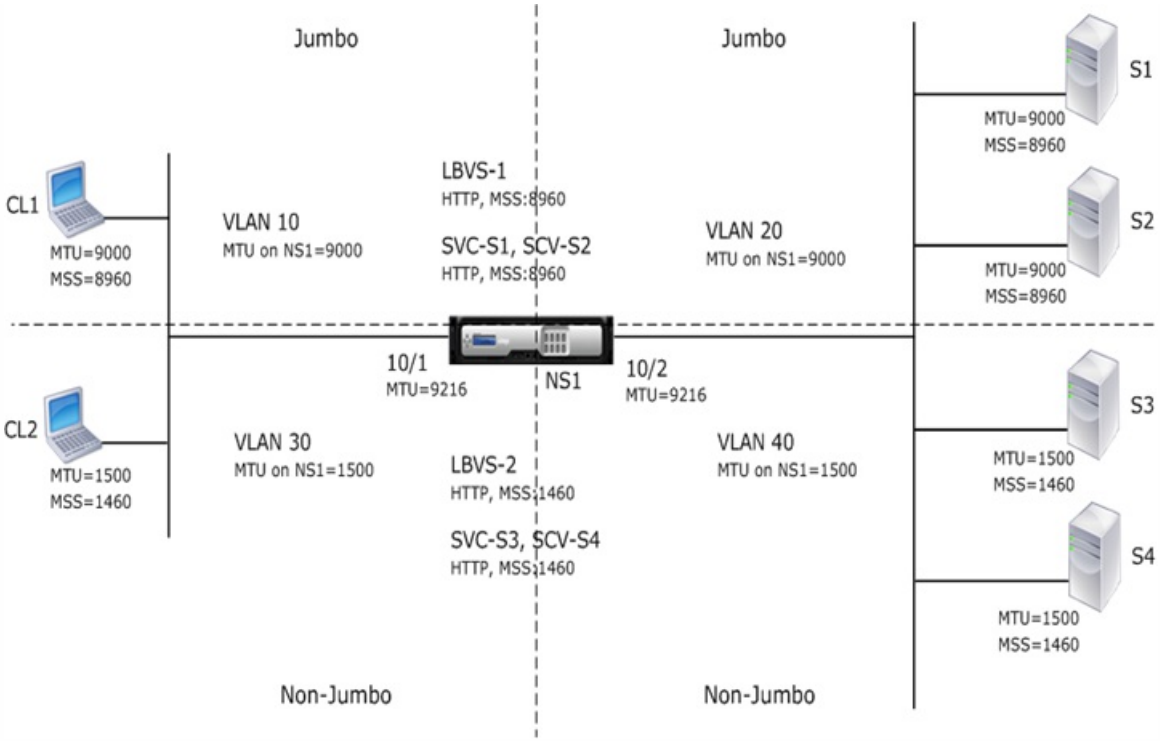
The effective MTU on a NetScaler interface for VLAN tagged packets is of the MTU of the interface or the MTU of the VLAN, whichever is lower. For example:

- The MTU of interface 10/1 is 9216. The MTU of VLAN 10 is 9000. On interface 10/1, the MTU of VLAN 10 tagged packets is 9000.
- The MTU of interface 10/2 is 9216. The MTU of VLAN 20 is 9000. On interface 10/2, the MTU of VLAN 20 tagged packets is 9000.
- The MTU of interface 10/1 is 9216. The MTU of VLAN 30 is 1500. On interface 10/1, the MTU of VLAN 30 tagged packets is 1500.
- The MTU of interface 10/2 is 9216. The MTU of VLAN 40 is 1500. On interface 10/2, the MTU of VLAN 40 tagged packets is 9000.

CL1, S1, S2, and all network devices between CL1 and S1 or S2 are configured for jumbo frames.

Since HTTP traffic is based on TCP, MSSs are set accordingly at each end point for supporting jumbo frames.

- For the connection between CL1 and virtual server LBVS-1 of NS1, the MSS on NS1 is set in a TCP profile, which is then bound to LBVS-1.
- For the connection between a SNIP address of NS1 and S1, the MSS on NS1 is set in a TCP profile, which is then bound to the service (SVC-S1) representing S1 on NS1.



The following table lists the settings used in this example.

Entity	Name	Details
IP address of clients	CL1	192.0.2.10
	CL2	192.0.3.20
IP address of servers	S1	198.51.100.19
	S2	198.51.100.20
	S3	198.51.101.19
	S4	198.51.101.20
SNIP addresses on NS1		• 198.51.100.18 • 198.51.101.18
MTU specified for interfaces and VLANs on NS1	10/1	9216
	10/2	9216
	VLAN 10	9000
	VLAN 20	9000
	VLAN 30	1500
	VLAN 40	1500

Default TCP profile	nstcp_default_profile	MSS:1460
Custom TCP profile	ALL-JUMBO	MSS: 8960
Services on NS1 representing servers	SVC-S1	• IP address: 198.51.100.19 • Protocol: HTTP • Port: 80 • TCP profile: ALL-JUMBO (MSS: 8960)
	SVC-S2	• IP address: 198.51.100.20 • Protocol: HTTP • Port: 80 • TCP profile: ALL-JUMBO (MSS: 8960)
	SVC-S3	• IP address: 198.51.101.19 • Protocol: HTTP • Port: 80 • TCP Profile: nstcp_default_profile (MSS:1460)
	SVC-S4	• IP address: 198.51.101.20 • Protocol: HTTP • Port: 80 • TCP Profile: nstcp_default_profile (MSS:1460)
Load balancing virtual servers on NS1	LBVS-1	• IP address = 203.0.113.15 • Protocol: HTTP • Port:80 • Bound services: SVC-S1, SVC-S2 • TCP profile: ALL-JUMBO (MSS: 8960)
	LBVS-2	• IP address = 203.0.114.15 • Protocol: HTTP • Port:80 • Bound services: SVC-S3, SVC-S4 • TCP Profile: nstcp_default_profile (MSS:1460)

Following is the traffic flow of CL1's request to S1:

1. Client CL1 creates a 20000-byte HTTP request to send to virtual server LBVS-1 of NS1.
2. CL1 opens a connection to LBVS-1 of NS1. CL1 and NS1 exchange their TCP MSS values while establishing the connection.
3. Because NS1's MSS value is smaller than the HTTP request, CL1 segments the request data into multiples of NS1's MSS

and sends these segments in IP packets tagged as VLAN 10 to NS1.
   - Size of the first two packets = [IP Header + TCP Header + (TCP segment=NS1 MSS)] = [20 + 20 + 8960] = 9000
   - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 2080] = 2120
4. NS1 receives these packets at interface 10/1. NS1 accepts these packets because the size of these packets is equal to or less than the effective MTU (9000) of interface 10/1 for VLAN 10 tagged packets.
5. From the IP packets, NS1 assembles all the TCP segments to form the 20000-byte HTTP request. NS1 processes this request.
6. LBVS-1's load balancing algorithm selects server S1, and NS1 opens a connection between one of its SNIP addresses and S1. NS1 and CL1 exchange their respective TCP MSS values while establishing the connection.
7. NS1 segments the request data into multiples of S1's MSS and sends these segments in IP packets tagged as VLAN 20 to S1.
   - Size of the first two packets = [IP Header + TCP Header + (TCP payload=S1 MSS)] = [20 + 20 + 8960] = 9000
   - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 2080] = 2120

Following is the traffic flow of S1's response to CL1:

1. Server S1 creates a 30000-byte HTTP response to send to the SNIP address of NS1.
2. S1 segments the response data into multiples of NS1's MSS and sends these segments in IP packets tagged as VLAN 20 to NS1. These IP packets are sourced from S1's IP address and destined to the SNIP address of NS1.
   - Size of first three packet = [IP Header + TCP Header + (TCP segment=NS1's MSS size)] = [20 + 20 + 8960] = 9000
   - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 3120] = 3160
3. NS1 receives the response packets at interface 10/2. NS1 accepts these packets, because their size is equal to or less than the effective MTU value (9000) of interface 10/2 for VLAN 20 tagged packets.
4. From these IP packets, NS1 assembles all the TCP segments to form the 30000-byte HTTP response. NS1 processes this response.
5. NS1 segments the response data into multiples of CL1's MSS and sends these segments in IP packets tagged as VLAN 10, from interface 10/1, to CL1. These IP packets are sourced from LBVS's IP address and destined to CL1's IP address.
   - Size of first three packet = [IP Header + TCP Header + [(TCP payload=CL1's MSS size)] = [20 + 20 + 8960] = 9000
   - Size of the last packet = [IP Header + TCP Header + (remaining TCP segment)] = [20 + 20 + 3120] = 3160

Updated: 2014-01-16

Following table lists tasks, commands, and examples for creating the required configuration on the NetScaler appliance.

Task	Syntax	Examples
Set the MTU of the desired interfaces for supporting jumbo frames	set interface <id> -mtu <positive_integer> show interface <id>	set int 10/1 –mtu 9216 set int 10/2 –mtu 9216
Create VLANs and set the MTU of the desired VLANs for supporting jumbo frames	add vlan <id> -mtu <positive_integer> show vlan <id>	add vlan 10 –mtu 9000 add vlan 20 –mtu 9000
		add vlan 30 –mtu 1500 add vlan 40 –mtu 1500

Task	Syntax	Examples
Bind interfaces to VLANs	bind vlan <id> -ifnum <interface_name> show vlan <id>	bind vlan 10 –ifnum 10/1 –tagged bind vlan 20 –ifnum 10/2 -tagged
		bind vlan 30 –ifnum 10/1 –tagged bind vlan 40 –ifnum 10/2 -tagged
Add a SNIP address	add ns ip <IPAddress> <netmask> -type SNIP show ns ip	add ns ip 198.51.100.18 255.255.255.0 –type SNIP
		add ns ip 198.51.101.18 255.255.255.0 –type SNIP
Create services representing HTTP servers	add service <serviceName> <ip> HTTP <port> show service <name>	add service SVC-S1 198.51.100.19 http 80 add service SVC-S2 198.51.100.20 http 80
		add service SVC-S3 198.51.101.19 http 80 add service SVC-S4 198.51.101.20 http 80
Create HTTP load balancing virtual servers and bind the services to it	add lb vserver <name> HTTP <ip> <port> bind lb vserver <vserverName> <serviceName> show lb vserver <name>	add lb vserver LBVS-1 http 203.0.113.15 80 bind lb vserver LBVS-1 SVC-S1 bind lb vserver LBVS-1 SVC-S2
		add lb vserver LBVS-2 http 203.0.114.15 80 bind lb vserver LBVS-2 SVC-S3 bind lb vserver LBVS-2 SVC-S4
Create a custom TCP profile and set its MSS for supporting jumbo frames	add tcpProfile <name> -mss <positive_integer>	add tcpprofile ALL-JUMBO –mss 8960

Task	Syntax	Examples
Bind the custom TCP profile to the desired load balancing virtual server and services	set service <Name> -tcpProfileName <string> show service <name>	set lb vserver LBVS-1 –tcpProfileName ALL-JUMBO set service SVC-S1 –tcpProfileName ALL-JUMBO set service SVC-S2 –tcpProfileName ALL-JUMBO
Save the configuration	save ns config show ns config	

show tcpProfile <name>

NetScaler Support for Microsoft Direct Access Deployment

Jul 11, 2016

Microsoft Direct Access is a technology that enables remote users to seamlessly and securely connect to the enterprise's internal networks, without the need to establish a separate VPN connection. Unlike VPN connections, which require user intervention to open and close connections, a Direct Access-enabled client connects automatically to the enterprise's internal networks whenever the client connects to the Internet.

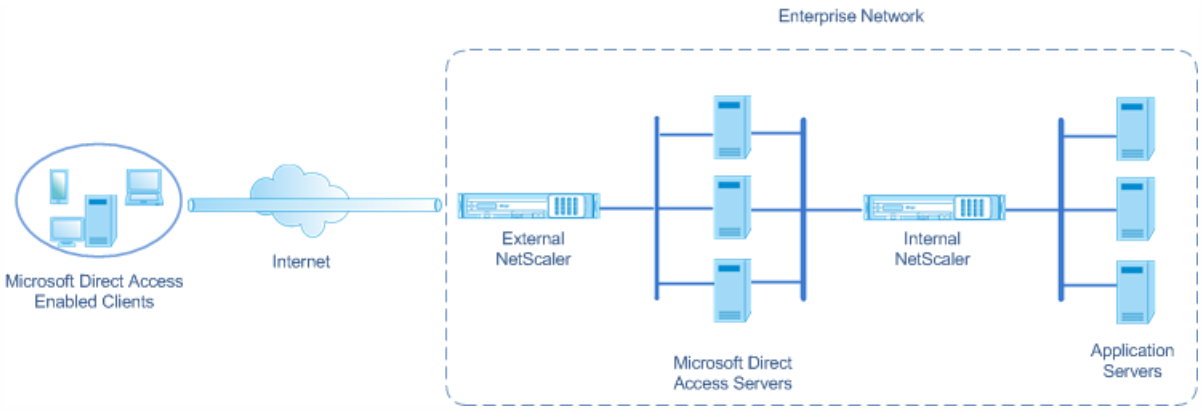
Manage-Out is a Microsoft Direct Access feature that allows administrators inside the enterprise network to connect to Direct Access clients outside the network and manage them (for example, performing administration tasks, such as scheduling service updates, and providing remote support.

In a Direct Access deployment, NetScaler appliances provide high availability, scalability, high performance, and security. NetScaler load balancing functionality sends client traffic through the most appropriate server. The appliances can also forward Manage-Out traffic through the right path to reach the client.

The architecture of a Microsoft Direct Access deployment consists of Direct Access enabled clients, Direct Access servers, application servers, and internal and external NetScaler appliances. Clients connect to an application server through a Direct Access server. An external NetScaler appliance load balance the client traffic to a Direct Access server, and an Internal NetScaler appliance forwards the client traffic from the Direct Access server to the destination application server. Direct Access is used for tunneling the client's IPv6 traffic over the IPv4 network. An IPv4 load balancing virtual server on the external NetScaler appliance load balances the client's tunneled traffic to one of the Direct Access servers. The Direct Access server extracts the IPv6 packets from the received client's IPv4 packets and sends them to the destination application server through the internal NetScaler appliance. The Internal NetScaler appliance has forwarding session rules with the source route cache option enabled for storing Layer 2 and Layer 3 connection information about the client's traffic from the Direct Access Server. The NetScaler appliance stores the following Layer 2 and Layer 3 information in a table called the source route cache table:

- Source IP address of the received packet
- MAC address of the Direct Access server that sent the packet
- VLAN ID of the NetScaler appliance that received the packet
- Interface ID of the NetScaler appliance that received the packet

The NetScaler appliance uses the information in the source route cache table for forwarding a response to the same Direct Access server because it has the tunneling information to reach the client. Also, the Internal NetScaler uses the source route cache table to forward application server's Manage-out traffic to the appropriate Direct Access server to reach a particular client.



To configure the Internal NetScaler appliance for forwarding an application server's response and manage-out traffic to the appropriate Direct Access Gateway, configure forwarding session rules. In each rule, set the sourceroutecache parameter to ENABLED.

To create a forwarding session rule by using the command line interface

At the command prompt, type:

- **add forwardingSession** <name> ((<network> [<netmask>]) | **-acl6name** <string> | **-aclname** <string>) **-sourceroutecache** (**ENABLED** | **DISABLED**]
- **show forwardingsession** <name>

Sample Configuration

In the following example, forwarding-session rule MS-DA-FW-1 is created on the internal NetScaler appliance. The forwarding session stores Layer 2 and Layer 3 information for any incoming IPv6 packets from a Direct Access server that matches source IPv6 prefix 2001:DB8::/96.

```
> add forwardingSession MS-DA-FW-1 2001:DB8::/96 -sourceroutecache -ENABLED

 Done
```

You can display the source route cache table for monitoring or detecting any unwanted connections between direct access servers and application servers.

To display the source route cache table by using the command line interface

At the command prompt, type:

show sourceroutecachetable

```
> show sourceroutecachetable

SOURCEIP          MAC               VLAN   INTERFACE

2001:DB8:5001:10  56:53:24:3d:02:eb  30     1/2

2001:DB8:5003:30  60:54:35:3e:04:bd  60     1/3

Done
```

You can clear all the entries from the source route cache table on a NetScaler appliance.

To clear the source route cache table by using the command line interface

At the command prompt, type:

- **flush ns sourceroutecachetable**

Configuring Allowed VLAN List

Feb 13, 2017

NetScaler accepts and sends tagged packets of a VLAN on an interface if the VLAN is explicitly configured on the NetScaler appliance and the interface is bound to the VLAN. Some deployments (for example, Bump in the wire) require the NetScaler appliance to function as a transparent device to accept and forward tagged packets related to a large number of VLANs. For this requirement, configuring and managing a large number of VLANs is not a feasible solution.

Allowed VLAN list on an interface specifies a list of VLANs. The interface transparently accepts and sends tagged packets related to the specified VLANs without the need for explicitly configuring these VLANs on the appliance.

Consider the following points before configuring allowed VLAN list

- In a high availability setup, allowed VLAN list is not propagated or synchronized. Therefore, you have to configure allowed VLAN list on both the nodes.
- The traffic of a native VLAN might leak to the non-member interfaces that specifies the native VLAN in its allowed VLAN list.
- A Maximum of 60 VLAN ranges can be specified as part of allowed VLAN list for an interface.
- The NetScaler appliance does not support allowed VLAN list on interfaces that are part of link aggregation channels or redundant interface sets. For more information on redundant interface set, see Redundant Interface Set.
- Allowed VLAN list is not supported on a NetScaler cluster configuration.
- The NetScaler appliance does not support allowed VLAN list for Bridge groups.
- The NetScaler appliance does not support allowed VLAN list for VXLANs.

To configure allowed VLAN list by using the NetScaler command line

At the command prompt, type:

- **set interface** <id> **-trunkmode** (ON | OFF) **-trunkAllowedVlan** <int[-int]> ...
- **show interface** <id>

To configure allowed VLAN list by using the NetScaler GUI

Navigate to **System** > **Network** > **Interfaces**, select a network interface, click **Edit**, and then set the following parameters:

- Trunk Mode
- Trunk Allowed VLAN

Sample Configuration

In the following sample configuration, VLANS in the ranges 100-120, 190-200, and 300-330 are specified as part of allowed VLAN list for interface 1/2.

Access Control Lists

May 10, 2012

Access Control Lists (ACLs) filter IP traffic and secure your network from unauthorized access. An ACL is a set of conditions that the NetScaler ADC evaluates to determine whether to allow access. For example, the Finance department probably does not want to allow its resources to be accessed by other departments, such as HR and Documentation, and those departments want to restrict access to their data.

When the NetScaler ADC receives a data packet, it compares the information in the data packet with the conditions specified in the ACL and allows or denies access. The administrator of the organization can configure ACLs to function in the following processing modes:

- ALLOW—Process the packet.
- BRIDGE—Bridge the packet to the destination without processing it. The packet is directly sent by Layer 2 and Layer 3 forwarding.
- DENY—Drop the packet.

ACL rules are the first level of defense on the NetScaler ADC.

NetScaler supports the following types of ACLs:

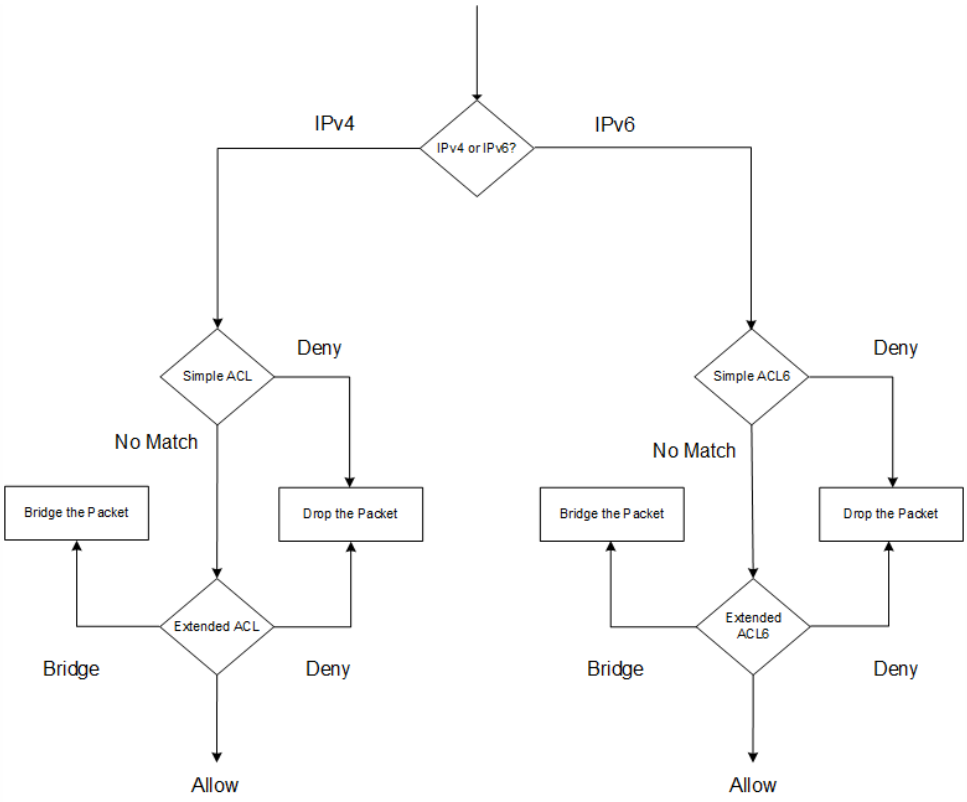
- **Simple ACLs** filter packets on the basis of their source IP address and, optionally, their protocol, destination port, or traffic domain. Any packet that has the characteristics specified in the ACL is dropped.
- **Extended ACLs** filter data packets on the basis of various parameters, such as source IP address, source port, action, and protocol. An extended ACL defines the conditions that a packet must satisfy for the NetScaler ADC to process the packet, bridge the packet, or drop the packet.

In the NetScaler user interfaces, the terms simple ACL and extended ACL refer to ACLs that process IPv4 packets. An ACL that processes IPv6 packets is called a simple ACL6 and or extended ACL6. When discussing both types, this documentation sometimes refers to both of them as simple ACLs or extended ACLs.

If both simple and extended ACLs are configured, incoming packets are compared to the simple ACLs first.

The NetScaler ADC first determines whether the incoming packet is an IPv4 or an IPv6 packet, and then compares the packet's characteristics to either simple ACLs or simple ACL6s. If a match is found, the packet is dropped. If no match is found, the packet is compared to extended ACLs or extended ACL6s. If that comparison results in a match, the packet is handled as specified in the ACL. The packet can be bridged, dropped, or allowed. If no match is found, the packet is allowed.

Figure 1. Simple and Extended ACLs Flow Sequence



Simple ACLs and Simple ACL6s

Feb 13, 2017

A simple ACL or simple ACL6 uses few parameters and can be configured only to drop IP packets. Packets can be dropped on the basis of their source IP address and, optionally, their protocol, destination port, or traffic domain.

When creating a simple ACL or simple ACL6, you can specify a time to live (TTL), in seconds, after which the ACL expires. ACLs with TTLs are not saved when you save the configuration. You can display simple ACLs and simple ACL6s to verify their configuration, and you can display their statistics.

This section includes the following details:

- Configuring Simple ACLs and Simple ACL6s
- Displaying Simple ACL and Simple ACL6 Statistics
- Terminating Established Connections

Configuring a simple ACL or simple ACL6 on a NetScaler ADC can include the following tasks.

- Create simple ACLs or simple ACL6s to drop (deny) packets on the basis of their source IP address and, optionally, their protocol, destination port, or traffic domain.
- Remove simple ACLs or simple ACL6s. These ACLs cannot be modified once created. If you need to modify a simple ACL or simple ACL6, you must remove it and create a new one.

To create a simple ACL by using the command line interface

At the command prompt, type the following commands to add an ACL and verify the configuration:

- **add ns simpleacl** <aclname> DENY **-srcIP** <ip_addr> [**-destPort**<port> **-protocol** (TCP | UDP)] [**-TTL** <positive_integer>]
- **show ns simpleacl** [<aclname>]

```
> add simpleacl rule1 DENY -srcIP 10.102.29.5 -TTL 600
Done
```

To create a simple ACL6 by using the command line interface

At the command prompt, type the following commands to add a simple ACL6 and verify the configuration:

- **add ns simpleacl6** <aclname> DENY **-srcIPv6** <ipv6_addr|null> [**-destPort**<port> **-protocol** (TCP | UDP)] [**-TTL** <positive_integer>]
- **show ns simpleacl6** [<aclname>]

```
>  add ns simpleacl6 rule1 DENY –srcIPv6 3ffe:192:168:215::82 -destPort 80 -Protocol TCP -TTL 9000
 Done
```

To remove a single simple ACL by using the command line interface

At the command prompt, type:

- **rm ns simpleacl** <aclname>
- **show ns simpleacl**

To remove a single simple ACL6 by using the command line interface

At the command prompt, type:

- **rm ns simpleacl6**<aclname>
- **show ns simpleacl6**

To remove all simple ACLs by using the command line interface

At the command prompt, type:

- **clear ns simpleacl**
- **show ns simpleacl**

To remove all simple ACL6s by using the command line interface

At the command prompt, type:

- **clear ns simpleacl6**
- **show ns simpleacl6**

To create a simple ACL by using the configuration utility

Navigate to System > Network > ACLs and, on the **Simple ACLs** tab, add a new simple ACL.

To create a simple ACL6 by using the configuration utility

Navigate to System > Network > ACLs and, on the **Simple ACL6s** tab, add a new simple ACL6.

To remove a single simple ACL by using the configuration utility

Navigate to System > Network > ACLs and, on the **Simple ACLs** tab, delete the simple ACL.

To remove a single simple ACL6 by using the configuration utility

Navigate to System > Network > ACLs and, on the **Simple ACL6s** tab, delete the simple ACL6.

To remove all simple ACLs by using the configuration utility

1. Navigate to System > Network > ACLs.
2. On the **Simple ACLs** tab, in the **Action** list, click **Clear**.

To remove all simple ACL6s by using the configuration utility

1. Navigate to System > Network > ACLs.
2. On the **Simple ACL6s** tab, in the **Action** list, click **Clear**.

You can display the simple ACL (or simple ACL6) statistics, which include the number of hits, the number of misses, and the number of simple ACLs configured.

The following table describes statistics you can display for simple ACLs and simple ACL6s.

Statistic	Indicates
ACL hits	Packets matching an ACL
ACL misses	Packets not matching any ACL
ACL count	Number of ACLs configured

To display simple ACL statistics by using the command line interface

At the command prompt, type:

stat ns simpleacl

```
> stat ns simpleacl

SimpleACL Statistics

                        Rate (/s)          Total
SimpleACL hits                  0              0
SimpleACL misses                0          51872
SimpleACLs count               --              2
Done
```

To display simple ACL6 statistics by using the command line interface

At the command prompt, type:

stat ns simpleacl6

To display simple ACL statistics by using the configuration utility

Navigate to System > Network > ACLs and, on the **Simple ACLs** tab, select the ACL and click **Statistics**.

To display simple ACL6 statistics by using the configuration utility

Navigate to System > Network > ACLs and, on the **Simple ACL6s** tab, select the simple ACL6 and click **Statistics**.

For a simple ACL or simple ACL6, the NetScaler ADC blocks any new connections that match the conditions specified in the ACL. Packets related to existing connections that were established before the ACL was created are not blocked. To terminate previously established connections that match an existing ACL, you can run a flush operation from the command line interface or the configuration utility.

Flush can be useful in the following cases:

- You receive a list of blacklisted IP addresses and want to completely block those IP addresses from accessing the NetScaler ADC. In this case, you create simple ACLs or simple ACL6s to block any new connections from these IP addresses, and then flush any existing connections associated with those addresses.
- You want to terminate a large number of connections from a particular network without taking the time to terminate them one by one.

When you run flush, the NetScaler ADC searches through all of its established connections and terminates those that match conditions specified in any of the simple ACLs configured on the ADC.

Note: If you plan to create more than one simple ACL and flush existing connections that match any of them, you can minimize the effect on performance by first creating all of the simple ACLs and then running flush only once.

To terminate all established IPv4 connections that match any of your configured simple ACLs by using the command line interface

At the command prompt, type:

```
flush simpleacl -estSessions
```

To terminate all established IPv6 connections that match any of your configured simple ACL6s by using the command line interface

At the command prompt, type:

```
flush simpleacl6 -estSessions
```

To terminate all established IPv4 connections that match any of your configured simple ACLs by using the configuration utility

1. Navigate to System > Network > ACLs.
2. On the **Simple ACLs** tab, in the **Action** list, click **Flush**.

To terminate all established IPv6 connections that match any of your configured simple ACL6s by using the configuration utility

1. Navigate to System > Network > ACLs.
2. On the **Simple ACL6s** tab, in the **Action** list, click **Flush**.

Extended ACLs and Extended ACL6s

Feb 13, 2017

Extended ACLs and extended ACL6s provide parameters and actions not available with simple ACLs. You can filter data on the basis of parameters such as source IP address, source port, action, and protocol. You can specify tasks to allow a packet, deny a packet, or bridge a packet.

Extended ACLs and ACL6s can be modified after they are created, and you can renumber their priorities to specify the order in which they are evaluated.

Note: If you configure both simple and extended ACLs, simple ACLs take precedence over extended ACLs.
The following actions can be performed on extended ACLs and ACL6s: Modify, Apply, Disable, Enable, Remove, and Renumber (the priority). You can display extended ACLs and ACL6s to verify their configuration, and you can display their statistics.

You can configure the NetScaler ADC to log details for packets that match an extended ACL. However, you cannot log details of packets that match an ext

Applying Extended ACLs and Extended ACL6s

Unlike simple ACLs and ACL6s, extended ACLs and ACL6s created on the NetScaler ADC do not work until they are applied. Also, if you make any modifications to an extended ACL or ACL6, such as disabling the ACLs, changing a priority, or deleting the ACLs, you must reapply the extended ACLs or ACL6s. You must also reapply them after enabling logging. The procedure to apply extended ACLs or ACL6s reapplies all of them. For example, if you have applied extended ACL rules 1 through 10, and you then create and apply rule 11, the first 10 rules are applied afresh.

If a session has a DENY ACL related to it, that session is terminated when you apply the ACLs.

Extended ACLs and ACL6s are enabled by default. When they are applied, the NetScaler ADC starts comparing incoming packets against them. However, if you disable them, they are not used until you reenable them, even if they are reapplied.

Renumbering the priorities of Extended ACLs and Extended ACL6s

Priority numbers determine the order in which extended ACLs or ACL6s are matched against a packet. An ACL with a lower priority number has a higher priority. It is evaluated before ACLs with higher priority numbers (lower priorities), and the first ACL to match the packet determines the action applied to the packet.

When you create an extended ACL or ACL6, the NetScaler ADC automatically assigns it a priority number that is a multiple of 10, unless you specify otherwise. For example, if two extended ACLs have priorities of 20 and 30, respectively, and you want a third ACL to have a value between those numbers, you might assign it a value of 25. If you later want to retain the order in which the ACLs are evaluated but restore their numbering to multiples of 10, you can use the renumber procedure.

This section includes the following details:

- Configuring Extended ACLs and Extended ACL6s
- Logging Extended ACLs (IPv4 Only)
- Displaying Extended ACL and Extended ACL6s Statistics
- Sample Configurations

Configuring an extended ACL or ACL6 on a NetScaler ADC consists of the following tasks.

- Create an extended ACL or ACL6 to either allow, deny, or bridge a packet. You can specify an IP address or range of IP addresses to match against the source or destination IP addresses of the packets. You can specify a protocol to match against the protocol of incoming packets.
- (Optional) You can modify extended ACLs or ACL6s that you previously created. Or, if you want to temporarily take one out of use you can disable it, and later reenable it.
- Apply extended ACLs or ACL6s. After you create, modify, disable or reenable, or delete an extended ACL or ACL6, you must apply the extended ACLs or ACL6s to activate them.
- (Optional) Renumber the priorities of extended ACLs or ACL6s. If you have configured ACLs with priorities that are not multiples of 10 and want to restore the numbering to multiples of 10, use the renumber procedure.

To create an extended ACL by using the command line interface

At the command prompt, type:

- **add ns acl** <aclname> <aclaction> [-**srcIP** [<operator>] <srcIPVal>] [-**srcPort** [<operator>] <srcPortVal>] [-**destIP** [<operator>] <destIPVal>] [-**destPort** [<operator>] <destPortVal>] [-**TTL** <positive_integer>] [-**srcMac** <mac_addr>] [(-**protocol** <protocol> [-established]) | -**protocolNumber** <positive_integer>] [-**vlan** <positive_integer>] [-**interface** <interface_name>] [-**icmpType** <positive_integer> [-**icmpCode** <positive_integer>]] [-**priority** <positive_integer>] [-**state** (ENABLED | DISABLED)] [-**logstate** (ENABLED | DISABLED) [-**ratelimit** <positive_integer>]]
- **show ns acl** [<aclName>]

```
> add ns acl restrict DENY -srcport 45-1024 -destIP 192.168.1.1 -protocol TCP
 Done
```

To create an extended ACL6 by using the command line interface

At the command prompt, type:

- **add ns acl6** <acl6name> <acl6action> [-**srcIPv6** [<operator>] <srcIPv6Val>] [-**srcPort** [<operator>] <srcPortVal>] [-**destIPv6** [<operator>] <destIPv6Val>] [-**destPort** [<operator>] <destPortVal>] [-**TTL** <positive_integer>] [-**srcMac** <mac_addr>] [(-**protocol** <protocol> [-established]) | -**protocolNumber** <positive_integer>] [-**vlan** <positive_integer>] [-**interface** <interface_name>] [-**icmpType** <positive_integer> [-icmpCode <positive_integer>]] [-**priority** <positive_integer>] [-**state** (ENABLED | DISABLED)]
- **show ns acl6** [<aclName>]

```
> add ns acl6 rule6  DENY -srcport 45-1024 -destIPv6 2001::45 -protocol TCP
 Done
```

To modify an extended ACL by using the command line interface

To modify an extended ACL, type the **set ns acl** command, the name of the extended ACL, and the parameters to be changed, with their new values.

To modify an extended ACL6 by using the command line interface

To modify an extended ACL6, type the **set ns acl** command, the name of the extended ACL6, and the parameters to be changed, with their new values.

To disable or enable an extended ACL by using the command line interface

At the command prompt, type one of the following commands:

- **disable ns acl** <aclname>
- **enable ns acl** <aclname>

To disable or enable an extended ACL6 by using the command line interface

At the command prompt, type one of the following commands:

- **disable ns acl6** <aclname>
- **enable ns acl6**<aclname>

To apply extended ACLs by using the command line interface

At the command prompt, type:

apply ns acls

To apply extended ACL6s by using the command line interface

At the command prompt, type:

apply ns acls6

To renumber the priorities of extended ACLs by using the command line interface

At the command prompt, type:

renumber ns acls

To renumber the priorities of extended ACL6s by using the command line interface

At the command prompt, type:

renumber ns acls6

To configure an extended ACL by using the configuration utility

Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACLs** tab, add a new extended ACL or edit an existing extended ACL. To enable or disable an existing extended ACL, select it, and then select **Enable** or **Disable** from the **Action** list.

To configure an extended ACL6sACL6s by using the configuration utility

Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACL6s** tab, add a new extended ACL6 or edit an existing extended ACL6. To enable or disable an existing extended ACL6, select it, and then select **Enable** or **Disable** from the **Action** list.

To apply extended ACLs by using the configuration utility

Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACLs** tab, in the **Action** list, click **Apply**.

To apply extended ACL6sACL6s by using the configuration utility

Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACL6s** tab, in the **Action** list, click **Apply**.

To renumber the priorities of extended ACLs by using the configuration utility

Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACLs** tab, in the **Action** list, click **Renumber Priority (s)**.

To renumber the priorities of extended ACL6sACL6s by using the configuration utility

Navigate to **System** > **Network** > **ACLs** and, on the **Extended ACL6s** tab, in the **Action** list, click **Renumber Priority (s)**.

You can configure the NetScaler ADC to log details for packets that match extended ACLs.

Note: You cannot enable logging for extended ACL6s.
In addition to the ACL name, the logged details include packet-specific information such as the source and destination IP addresses. The information is stored either in the syslog file or in the nslog file, depending on the type of global logging (syslog or nslog) enabled.

Logging must be enabled at both the global level and the ACL level. The global setting takes precedence. For more information about enabling logging globally, see "."

To optimize logging, when multiple packets from the same flow match an ACL, only the first packet's details are logged, and the counter is incremented for every packet that belongs to the same flow. A flow is defined as a set of packets that have the same values for the source IP address, destination IP address, source port, destination port, and protocol parameters. To avoid flooding of log messages, the NetScaler ADC performs internal rate limiting so that packets belonging to the same flow are not repeatedly logged. The total number of different flows that can be logged at any given time is limited to 10,000.

Note: You must apply ACLs after you enable logging.

To configure extended ACL Logging by using the command line interface

At the command prompt, type the following commands to configure logging and verify the configuration:

- **set ns acl** <aclName> [-**logState** (ENABLED | DISABLED)] [-**rateLimit** <positive_integer>]
- **show ns acl** [<aclName>]

> set ns acl restrict -logstate ENABLED -ratelimit 120
Warning: ACL modified, apply ACLs to activate change

To configure extended ACL Logging by using the configuration utility

1. Navigate to System > Network > ACLs and, on the **Extended ACLs** tab, open the extended ACL.
2. Set the following parameters:
   - **Log State**—Enable or disable logging of events related to the extended ACL rule. The log messages are stored in the configured syslog or auditlog server.

- **Log Rate Limit**—Maximum number of log messages to be generated per second. If you set this parameter, you must enable the Log State parameter.

You can display statistics of extended ACLs and ACL6s.

The following table lists the statistics associated with extended ACLs and ACL6s, and their descriptions.

Statistic	Specifies
Allow ACL hits	Packets matching ACLs with processing mode set to ALLOW. The NetScaler ADC processes these packets.
NAT ACL hits	Packets matching a NAT ACL, resulting in a NAT session.
Deny ACL hits	Packets dropped because they match ACLs with processing mode set to DENY.
Bridge ACL hits	Packets matching a bridge ACL, which in transparent mode bypasses service processing.
ACL hits	Packets matching an ACL.
ACL misses	Packets not matching any ACL.

To display the statistics of all extended ACLs by using the command line interface

At the command prompt, type:

```
stat ns acl
```

To display the statistics of all extended ACL6s by using the command line interface

At the command prompt, type:

```
stat ns acl6
```

To display the statistics of an extended ACL by using the configuration utility

Navigate to System > Network > ACLs, on the **Extended ACLs** tab, select the extended ACL, and click **Statistics**.

To display the statistics of an extended ACL6 by using the configuration utility

Navigate to System > Network > ACLs, on the **Extended ACL6s** tab, select the extended ACL, and click **Statistics**.

The following table shows examples of configuring extended ACL rules through the command line interface.

Action - ALLOW	
Tasks	Steps

Create an extended ACL rule to allow a particular host to access the servers.	>add ns acl allow-client ALLOW -srcIP = 40.40.40.1 Done
Create an extended ACL rule to allow a particular network to access the servers.	>add ns acl allow-client-net ALLOW -srcIP = 40.40.40.0-40.40.40.255 Done
Create extended ACL rules to allow HTTP, TFTP, and ICMP traffic.	>add acl allow-http ALLOW -protocol tcP -destport 80 Done Done >add acl allow-tftp ALLOW -protocol udp -destport 69 Done >add acl allow-icmp ALLOW -protocol icmp Done
Create an extended ACL rule to allow access to a particular destination/network.	>add acl allow-dest-access ALLOW -destip 20.20.20.0-20.20.20.255 Done
Create an extended ACL rule to allow traffic coming from a particular VLAN.	>add acl allow-vlan ALLOW -vlan 3000 Done
Action - DENY	
Tasks	**Steps**
Create an extended ACL rule to deny access to the servers by a particular host.	>add ns acl deny-client DENY -srcIP = 50.50.50.1 Done
Create an extended ACL rule to deny access to the servers from a particular network.	> add ns acl deny-client-net DENY -srcIP = 50.50.50.0-50.50.50.255 Done
Create extended ACL rules to deny Telnet and FTP traffic.	>add ns acl deny-client-Telnet DENY -protocol TCP -destPort 23 Done > add ns acl deny-client-FTP DENY -protocol TCP -

	destPort 20-21 Done
Create an extended ACL rule to deny TCP traffic to port 80 from a particular host/network.	>add ns acl deny-client-TCP DENY -protocol TCP -destPort 80 -destIP 20.20.20.0-20.20.20.255 Done
Create an extended ACL rule to deny traffic from a particular VLAN.	> add acl deny-vlan DENY -vlan 2000 Done
Action - BRIDGE	
Tasks	**Steps**
Create an extended ACL rule to bridge FTP traffic.	>add ns acl bridge-ftp BRIDGE -protocol TCP -destport 21 Done >add ns acl bridge-ftp-data BRIDGE -protocol TCP -destport 21 Done
Create an extended ACL rule to bridge all traffic from a particular VLAN.	>add ns acl bridge-client-vlan BRIDGE -vlan 1000 Done
MAC Address Filtering	
Tasks	**Steps**
Create an extended ACL rule to allow traffic from a particular MAC address to a particular host.	>add ns acl allow-mac-host ALLOW -srcMAC 2a:c1:69:92:a0:7b -destIP 10.10.10.1 Done
Create an extended ACL rule to allow traffic from hosts with a specific MAC UUID.	> add ns acl allow-mac-uuid ALLOW -srcMAC 2a:c1:69:92:a0:7b -srcMacMask 000000111111 Done
ACL with RNAT (Typically, RNAT is used to allow servers configured with private non-routable IP addresses to initiate connections to the Internet.)	

Tasks	Steps
Create an RNAT rule for a particular host.	>add ns acl rnat-acl-host ALLOW -srcIP 40.40.40.1 Done >apply ns acls Done >set rnat rnat-acl Done
Create an RNAT rule for a particular network.	>add ns acl rnat-acl-network ALLOW -srcIP 40.40.40.0-40.40.40.255 Done >set rnat rnat-acl-network -NATIP 5.5.5.1 Done
ACL with Forwarding Session	
Create a forwarding session rule for a case in which a client request forwarded to a server results in a response that has to return by the same path.	>add ns acl forward-acl-host ALLOW -srcIP 20.20.20.1 Done >add forwardingSession fs -aclname forward-acl-host Done

MAC Address Wildcard Mask for ACLs

Jan 31, 2011

A wildcard mask parameter has been introduced for extended ACLs and ACL6s and is used with the source MAC address parameter to define a range of MAC addresses to be match against the source MAC address of incoming packets.

Wild card masks specify which hexadecimal digits of the MAC address are used and which hexadecimal digits are ignored. The wildcard mask parameter specifies a series of ones and zeroes and has a length of 12 digits. Each digit is a mask for the corresponding hexadecimal digit of the MAC address. A zero digit in the wildcard mask indicates that the corresponding hexadecimal digit of the MAC address must be considered and a one digit indicates that the corresponding hexadecimal digit to be ignored.

The wildcard mask should meet the following conditions:

- Has only one series of zeroes
- Has only one series of ones
- Start with a series of zeroes

The following are some of the examples of valid wildcard masks:

- 000000111111
- 000000011111
- 000011111111

The following are some of the examples of invalid wildcard masks:

- 000000111100
- 111110000000
- 010101010101

For an ACL, a wildcard mask of 000000111111 for MAC address 96:fa:95:1d:67:4a defines the MAC address range 96:FA:95:00:00:00 - 96:FA:95:FF:FF:FF. This MAC address range is matched against the source MAC address of the incoming packets.

To specify a range of source MAC addresses in an ACL rule by using the NetScaler command line

At the command prompt, type:

- add ns acl <name> <action> -srcMac <mac_addr> -srcMacMask <string>
- show ns acl <aclname>

Example

```
> add ns acl ACL-1 ALLOW –protocol TCP –srcport 2000-3000 -srcMac 96:fa:95:1d:67:4a
 –srcMacMask 000000111111
Done
```

To specify a range of source MAC addresses in an ACL6 rule by using the NetScaler command line

At the command prompt, type:

- add ns acl6 <name> <action> -srcMac <mac_addr> -srcMacMask <string>
- show ns acl6 <acl6name>

Example

```
> add ns acl6 ACL6-1 ALLOW -destIPv6 2001::45 -srcMac 96:fa:90:1d:67:4a
```

```
–srcMacMask 000000001111
Done
```

Blocking Traffic on Internal Ports

Jan 31, 2011

The NetScaler appliance does not block traffic that matches an ACL rule if the traffic is destined to the appliance's NSIP address, or one of its SNIP addresses, and a port in the 3008-3011 range.

This behavior is now specified by the default setting of the new Implicit ACL Allow (implicitACLAllow) parameter (of the L3 param command). You can disable this parameter if you want to block traffic to ports in the 3008-3011 range. An appliance in a high availability configuration makes an exception for its partner (primary or secondary) node. It does not block traffic from that node.

To disable or enable this parameter by using the command line interface

At the command prompt, type:

set l3param -implicitACLAllow [ENABLED | DISABLED]

Note: The parameter implicitACLAllow is enabled by default.

Example

> set l3param -implicitACLAllow DISABLED

Done

IP Routing

Sep 06, 2013

NetScaler appliances support both dynamic and static routing. Because simple routing is not the primary role of a NetScaler, the main objective of running dynamic routing protocols is to enable route health injection (RHI), so that an upstream router can choose the best among multiple routes to a topographically distributed virtual server.

Most NetScaler implementations use some static routes to reduce routing overhead. You can create backup static routes and monitor routes to enable automatic switchover in the event that a static route goes down. You can also assign weights to facilitate load balancing among static routes, create null routes to prevent routing loops, and configure IPv6 static routes. You can configure policy based routes (PBRs), for which routing decisions are based on criteria that you specify.

This document includes the following information:

- Configuring Dynamic Routes
- Configuring Static Routes
- Route Health Injection Based on Virtual Server Settings
- Configuring Policy-Based Routes
- Troubleshooting Routing Issues

Configuring Dynamic Routes

Feb 13, 2017

When a dynamic routing protocol is enabled, the corresponding routing process monitors route updates and advertises routes. Routing protocols enable an upstream router to use the equal cost multipath (ECMP) technique to load balance traffic to identical virtual servers hosted on two standalone NetScaler appliances. Dynamic routing on a NetScaler appliance uses three routing tables. In a high-availability setup, the routing tables on the secondary appliance mirror those on the primary.

For command reference guides and unsupported commands on dynamic routing protocol, see Dynamic Routing Protocol Command Reference Guides and Unsupported Commands.

The NetScaler supports the following protocols:

- Routing Information Protocol (RIP) version 2
- Open Shortest Path First (OSPF) version 2
- Border Gateway Protocol (BGP)
- Routing Information Protocol next generation (RIPng) for IPv6
- Open Shortest Path First (OSPF) version 3 for IPv6
- ISIS Protocol

You can enable more than one protocol simultaneously.

Routing Tables in the NetScaler

In a NetScaler appliance, the NetScaler kernel routing table, the FreeBSD kernel routing table, and the NSM FIB routing table each hold a different set of routes and serve a different purpose. They communicate with each other by using UNIX routing sockets. Route updates are not automatically propagated from one routing table to another. You must configure propagation of route updates for each routing table.

NS Kernel Routing Table

The NS kernel routing table holds subnet routes corresponding to the NSIP and to each SNIP and MIP. Usually, no routes corresponding to VIPs are present in the NS kernel routing table. The exception is a VIP added by using the **add ns ip** command and configured with a subnet mask other than 255.255.255.255. If there are multiple IP addresses belonging to the same subnet, they are abstracted as a single subnet route. In addition, this table holds a route to the loopback network (127.0.0.0) and any static routes added through the command line interface (CLI). The entries in this table are used by the NetScaler in packet forwarding. From the NetScaler CLI, they can be inspected with the **show route** command.

FreeBSD Routing Table

The sole purpose of the FreeBSD routing table is to facilitate initiation and termination of management traffic (telnet, ssh, etc.). In a NetScaler appliance, these applications are tightly coupled to FreeBSD, and it is imperative for FreeBSD to have the necessary information to handle traffic to and from these applications. This routing table contains a route to the NSIP subnet and a default route. In addition, FreeBSD adds routes of type WasCloned(W) when the NetScaler establishes connections to hosts on local networks. Because of the highly specialized utility of the entries in this routing table, all other route updates from the NS kernel and NSM FIB routing tables bypass the FreeBSD routing table. Do not modify it with the **route** command. The FreeBSD routing table can be inspected by using the **netstat** command from any UNIX shell.

Network Services Module (NSM) FIB

The NSM FIB routing table contains the advertisable routes that are distributed by the dynamic routing protocols to their peers in the network. It may contain:

Connected routes

IP subnets that are directly reachable from the NetScaler. Typically, routes corresponding to the NSIP subnet and subnets over which routing protocols are enabled are present in NSM FIB as connected routes.

Kernel routes

All the VIP addresses on which the -hostRoute option is enabled are present in NSM FIB as kernel routes if they satisfy the required RHI Levels. In addition, NSM FIB contains any static routes configured on the NetScaler CLI that have the -advertise option enabled. Alternatively, if the NetScaler is operating in Static Route Advertisement (SRADV) mode, all static routes configured on the NetScaler CLI are present in NSM FIB. These static routes are marked as kernel routes in NSM FIB, because they actually belong to the NS kernel routing table.

Static routes

Normally, any static route configured in VTYSH is present in NSM FIB. If administrative distances of protocols are modified, this may not always be the case. An important point to note is that these routes can never get into the NS kernel routing table.

Learned routes

If the NetScaler is configured to learn routes dynamically, the NSM FIB contains routes learned by the various dynamic routing protocols. Routes learned by OSPF, however, need special processing. They are downloaded to FIB only if the fib-install option is enabled for the OSPF process. This can be done from the router-config view in VTYSH.

High Availability Setup

In a high availability setup, the primary node runs the routing process and propagates routing table updates to the secondary node. The routing table of the secondary node mirrors the routing table on the primary node.

Non-Stop Forwarding

After failover, the secondary node takes some time to start the protocol, learn the routes, and update its routing table. But this does not affect routing, because the routing table on the secondary node is identical to the routing table on the primary node. This mode of operation is known as non-stop forwarding.

Black Hole Avoidance Mechanism

After failover, the new primary node injects all its VIP routes into the upstream router. However, that router retains the old primary node's routes for 180 seconds. Because the router is not aware of the failover, it attempts to load balance traffic between the two nodes. During the 180 seconds before the old routes expire, the router sends half the traffic to the old, inactive primary node, which is, in effect, a black hole.

To prevent this, the new primary node, when injecting a route, assigns it a metric that is slightly lower than the one specified by the old primary node.

Interfaces for Configuring Dynamic Routing

To configure dynamic routing, you can use either the configuration utility or a command-line interface. The NetScaler supports two independent command-line interfaces: the NetScaler CLI and the Virtual Teletype Shell (VTYSH). The

NetScaler CLI is the appliance's native shell. VTYSH is exposed by ZebOS. The NetScaler routing suite is based on ZebOS, the commercial version of GNU Zebra.

Note: Citrix recommends that you use VTYSH for all commands except those that can be configured only on the NetScaler CLI. Use of the NetScaler CLI should generally be limited to commands for enabling the routing protocols, configuring host route advertisement, and adding static routes for packet forwarding.

Dynamic Routing Protocol Command Reference Guides and Unsupported Commands

The following table lists command reference guide links, for various dynamic routing protocols, and unsupported commands on the NetScaler appliance:

Dynamic Routing Protocol	Command Reference Guide	Unsupported Commands
OSPF	OSPF Command Reference	• Domain-id command • OSPF-TE related commands • OSPF-VPN related commands • CSPF-TE related commands • ip ospf resync-timeout command • capability opaque command • enable ext-ospf-multi-inst command
IPv6 OSPF (OSPFv3)	OSPF Command Reference	• OSPF-TE related commands
BGP	BGP Command Reference	• VPN/VRF related commands • MPLS related commands • 6PE commands (IPv6 provider edge) • MD5 authentication related commands • Multicast options • set-overload-bit command
IS-IS	IS-IS Command Reference	• capability cspf command • enable-cspf command • mpls traffic-eng command • mpls traffic-eng router-id command • multi-topology for ipv6 address family related commands
RIP and IPv6 RIP (RIPng)	-	• neighbor command

Configuring RIP

Mar 20, 2012

Routing Information Protocol (RIP) is a Distance Vector protocol. The NetScaler supports RIP as defined in RFC 1058 and RFC 2453. RIP can run on any subnet.

After enabling RIP, you need to configure advertisement of RIP routes. For troubleshooting, you can limit RIP propagation. You can display RIP settings to verify the configuration.

Enabling and Disabling RIP

Updated: 2013-08-30

Use either of the following procedures to enable or disable RIP. After you enable RIP, the NetScaler appliance starts the RIP process. After you disable RIP, the appliance stops the RIP process.

To enable or disable RIP routing by using the command line interface

At the command prompt, enter one of the following commands to enable or disable RIP:

- enable ns feature RIP
- disable ns feature RIP

To enable or disable RIP routing by using the configuration utility

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the RIP Routing option.

Advertising Routes

Updated: 2013-08-30

RIP enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone NetScaler appliances. Route advertisement enables an upstream router to track network entities located behind the NetScaler.

To configure RIP to advertise routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router rip	Start the RIP routing process and enter configuration mode for the routing process.
redistribute static	Redistribute static routes.

Command	Specifies
redistribute kernel	Redistribute kernel routes.

Example:

```
>VTYSH
NS# configure terminal
NS(config)# router rip
NS(config-router)# redistribute static
NS(config-router)# redistribute kernel
```

Limiting RIP Propagations

Updated: 2013-08-30

If you need to troubleshoot your configuration, you can configure listen-only mode on any given interface.

To limit RIP propagation by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router rip	Start the RIP routing process and enter configuration mode for the routing process.
passive-interface < vlan_name>	Suppress routing updates on interfaces bound to the specified VLAN.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router rip
NS(config-router)# passive-interface VLAN0
```

Verifying the RIP Configuration

Updated: 2013-08-30

You can display the routing table and other RIP settings.

To view the RIP settings by using the VTYSH command line

At the command prompt, type the following commands in the following order:

Command	Specifies
VTYSH	Display VTYSH command prompt.

Command	Specifies
sh rip	Display updated RIP routing table.
sh rip interface <vlan_name>	Displays RIP information for the specified VLAN.

Example

NS# VTYSH
NS# sh rip
NS# sh rip interface VLAN0

Configuring OSPF

Jul 07, 2016

The NetScaler supports Open Shortest Path First (OSPF) Version 2 (RFC 2328). The features of OSPF on the NetScaler are:

- If a vserver is active, the host routes to the vserver can be injected into the routing protocols.
- OSPF can run on any subnet.
- Route learning advertised by neighboring OSPF routers can be disabled on the NetScaler.
- The NetScaler can advertise Type-1 or Type-2 external metrics for all routes.
- The NetScaler can advertise user-specified metric settings for VIP routes. For example, you can configure a metric per VIP without special route maps.
- You can specify the OSPF area ID for the NetScaler.
- The NetScaler supports not-so-stubby-areas (NSSAs). An NSSA is similar to an OSPF stub area but allows injection of external routes in a limited fashion into the stub area. To support NSSAs, a new option bit (the N bit) and a new type (Type 7) of Link State Advertisement (LSA) area have been defined. Type 7 LSAs support external route information within an NSSA. An NSSA area border router (ABR) translates a type 7 LSA into a type 5 LSA that is propagated into the OSPF domain. The OSPF specification defines only the following general classes of area configuration:
  - Type 5 LSA: Originated by routers internal to the area are flooded into the domain by AS boarder routers (ASBRs).
  - Stub: Allows no type 5 LSAs to be propagated into/throughout the area and instead depends on default routing to external destinations.

After enabling OSPF, you need to configure advertisement of OSPF routes. For troubleshooting, you can limit OSPF propagation. You can display OSPF settings to verify the configuration.

Enabling and Disabling OSPF

Updated: 2013-09-05

To enable or disable OSPF, you must use either the command line interface or the configuration utility. When OSPF is enabled, the NetScaler starts the OSPF process. When OSPF is disabled, the NetScaler stops the OSPF routing process.

To enable or disable OSPF routing by using the command line interface

At the command prompt, type one of the following commands:

1. enable ns feature OSPF
2. disable ns feature OSPF

To enable or disable OSPF routing by using the configuration utility

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the OSPF Routing option.

Advertising OSPF Routes

Updated: 2013-08-30

OSPF enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone NetScaler appliances. Route advertising enables an upstream router to track network entities located behind the NetScaler.

To configure OSPF to advertise routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enters global configuration mode.
router OSPF	Start OSPF routing process and enter configuration mode for the routing process.
network A.B.C.D/M area <0-4294967295>	Enable routing on an IP network.
redistribute static	Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router OSPF
NS(config-router)# network 10.102.29.0/24 area 0
NS(config-router)# redistribute static
NS(config-router)# redistribute kernel
```

Limiting OSPF Propagations

Updated: 2013-08-30

If you need to troubleshoot your configuration, you can configure listen-only mode on any given VLAN.

To limit OSPF propagation by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router OSPF	Start OSPF routing process and enters configuration mode for the routing process.
passive-interface < vlan_name>	Suppress routing updates on interfaces bound to the specified VLAN.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router OSPF
NS(config-router)# passive-interface VLAN0
```

Verifying the OSPF Configuration

Updated: 2013-08-30

You can display current OSPF neighbors, and OSPF routes.

To view the OSPF settings by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
sh OSPF neighbor	Displays current neighbors.
sh OSPF route	Displays OSPF routes.

Example

```
>VTYSH
NS# sh ip OSPF neighbor
NS# sh ip OSPF route
```

Configuring Graceful Restart for OSPF

In a non-INC high availability (HA) setup in which a routing protocol is configured, after a failover, routing protocols are converged and routes between the new primary node and the adjacent neighbor routers are learned. Route learning take some time to complete. During this time, forwarding of packets is delayed, network performance might get disrupted, and packets might get dropped.

Graceful restart enables an HA setup during a failover to direct its adjacent routers to not remove the old primary node's learned routes from their routing databases. Using the old primary node's routing information, the new primary node and the adjacent routers immediately start forwarding packets, without disrupting network performance.

To configure graceful restart for OSPF by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Example	Command Description
VTYSH	VTYSH	Enters VTYSH command prompt.

Command	Example	Command Description
terminal		
router-id <id>	NS(config)# router-id 1.1.1.1	Sets a router identifier for the NetScaler appliance. This identifier is set for all the dynamic routing protocols. The same ID must be specified in the other node in a high availability set up for graceful restart to work properly in the HA setup.
ospf restart grace-period <1-1800>	NS(config)# ospf restart grace-period 170	Specifies the grace period, in seconds, for which the routes are to be preserved in the helper devices. Default value: 120 seconds.
ospf restart helper max-grace-period <1-1800>	NS(config)# ospf restart helper max-grace-period 180	This is an optional command to limit the maximum grace period for which the NetScaler appliance will be in the helper mode. If the NetScaler appliance receives an opaque LSA with grace-period greater than the set helper max-grace-period, the LSA is discarded and the NetScaler is not placed in helper mode.
router ospf	NS(config)# router ospf	Starts OSPF routing process and enter configuration mode for the routing process.
network A.B.C.D/M area <0-4294967295>	NS(config-router)# network 192.0.2.0/24 area 0	Enables routing on an IP network.
capability restart graceful	NS(config-router)# capability restart graceful	Enables graceful restart on the OSPF routing process.
redistribute kernel	NS(config-router)# redistribute kernel	Redistributes kernel routes.

Configuring BGP

Jul 07, 2016

The NetScaler appliance supports BGP (RFC 4271). The features of BGP on the NetScaler are:

- The NetScaler advertises routes to BGP peers.
- The NetScaler injects host routes to virtual IP addresses (VIPs), as determined by the health of the underlying virtual servers.
- The NetScaler generates configuration files for running BGP on the secondary node after failover in an HA configuration.
- This protocol supports IPv6 route exchanges.
- As-Override Support in Border Gateway Protocol

After enabling BGP, you need to configure advertisement of BGP routes. For troubleshooting, you can limit BGP propagation. You can display BGP settings to verify the configuration.

Prerequisites for IPv6 BGP

Before you begin configuring IPv6 BGP, do the following:

- Make sure that you understand the IPv6 BGP protocol.
- Install the IPv6PT license on the NetScaler appliance.
- After installing the IPv6PT license, enable the IPv6 feature.

Enabling and Disabling BGP

Updated: 2013-09-05

To enable or disable BGP, you must use either the command line interface or the configuration utility. When BGP is enabled, the NetScaler appliance starts the BGP process. When BGP is disabled, the appliance stops the BGP process.

To enable or disable BGP routing by using the command line interface

At the command prompt, type one of the following commands:

- enable ns feature BGP
- disable ns feature BGP

To enable or disable BGP routing by using the configuration utility

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the BGP Routing option.

Advertising IPv4 Routes

Updated: 2013-08-30

You can configure the NetScaler appliance to advertise host routes to VIPs and to advertise routes to downstream networks.

To configure BGP to advertise IPv4 routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter. Possible values: 1 to 4,294,967,295.
Neighbor < IPv4 address> remote-as < as-number>	Update the IPv4 BGP neighbor table with the link local IPv4 address of the neighbor in the specified autonomous system.
Address-family ipv4	Enter address family configuration mode.
Neighbor < IPv4 address> activate	Exchange prefixes for the IPv4 router family between the peer and the local node by using the link local address.
redistribute kernel	Redistribute kernel routes.
redistribute static	Redistribute static routes.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router BGP 5
NS(config-router)# Neighbor a1bc::102 remote-as 100
NS(config-router)# Address-family ipv4
NS(config-router-af)# Neighbor 10.102.29.170 activate
NS(config-router)# redistribute kernel
NS(config-router)# redistribute static
```

Advertising IPv6 BGP Routes

Updated: 2013-08-30

Border Gateway Protocol (BGP) enables an upstream router to load balance traffic between two identical virtual servers hosted on two standalone NetScaler appliances. Route advertising enables an upstream router to track network entities located behind the NetScaler.

To configure BGP to advertise IPv6 routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter. Possible values: 1 to 4,294,967,295.
Neighbor < IPv6 address> remote-as < as-number>	Update the IPv6 BGP neighbor table with the link local IPv6 address of the neighbor in the specified autonomous system.
Address-family ipv6	Enter address family configuration mode.
Neighbor < IPv6 address> activate	Exchange prefixes for the IPv6 router family between the peer and the local node by using the link local address.
redistribute kernel	Redistribute kernel routes.
redistribute static	Redistribute static routes.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router BGP 5
NS(config-router)# Neighbor a1bc::102 remote-as 100
NS(config-router)# Address-family ipv6
NS(config-router-af)# Neighbor a1bc::102 activate
NS(config-router)# redistribute kernel
NS(config-router)# redistribute static
```

Verifying the BGP Configuration

Updated: 2013-08-30

You can use VTYSH to display BGP settings.

To view the BGP settings using the VTYSH command line

At the command prompt, type:

```
VTYSH
```

You are now in the VTYSH command prompt. An output similar to the following appears:

```
NS170#
```

At the VTYSH command prompt, type:

```
NS170# sh ip BGP
NS170# sh BGP
NS170# sh ip BGP neighbors
NS170# sh ip BGP summary
NS170# sh ip BGP route-map <map-tag>
```

As-Override Support in Border Gateway Protocol

As a part of BGP loop prevention functionality, if a router receives a BGP packet containing the router's Autonomous System Number (ASN) in the Autonomous Systems (AS) path, the router drops the packet. The assumption is that the packet originated from the router and has reached the place from where it originated.

If an enterprise has several sites with a same ASN, BGP loop prevention causes the sites with an identical ASN to not get linked by another ASN. Routing updates (BGP packets) are dropped when another site receives them.

To solve this issue, BGP AS-Override functionality has been added to the ZebOS BGP routing module of the NetScaler.

With AS-Override enabled for a peer device, when the NetScaler appliance receives a BGP packet for forwarding to the peer, and the ASN of the packet matches that of the peer, the appliance replaces the ASN of the BGP packet with its own ASN number before forwarding the packet.

You can enable AS-Override for a specific neighbor or a group of neighbors (peer group) by using the vtysh command line.

To configure BGP AS-Override for a IPv4 neighbor by using the VTYSH command line

Command	Specifies
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter.
Neighbor < IPv4 address> remote-as < as-number>	Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system.
Neighbor <IPv4 address> as-override	Enable BGP as-override for the specified neighbor.

> VTYSH NS# configure terminal
NS(config)# router BGP 200
NS(config-router)# Neighbor 192.0.2.100 remote-as 100
NS(config-router)# Neighbor 10.102.29.100 as-override

To configure BGP AS-Override for a IPv4 BGP peer group by using the VTYSH command line

Command	Specifies
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter.
Neighbor <peer group name> **peer-group**	Create a BGP peer group.
Neighbot <IPv4 address> **peer-group** <peer group name>	Associate neighbors to the specified peer group.
Neighbor <peer group name> remote-as < as-number>	Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system.

Neighbor <peer group name> as-override	Enable BGP as-override for all the neighbors that are associated with the specified peer group.

> VTYSH NS# configure terminal
NS(config)# router BGP 200
NS(config-router)# neighbor external-peers-1 peer-group
NS(config-router)# neighbor 192.0.2.101 peer-group external-peers-1
NS(config-router)# neighbor 192.0.2.102 peer-group external-peers-1
NS(config-router)# neighbor 192.0.2.103 peer-group external-peers-1
NS(config-router)# Neighbor external-peers-1 remote-as 100
NS(config-router)# Neighbor external-peers-1 as-override

To configure BGP AS-Override for an IPv6 neighbor by using the VTYSH command line

Command	Specifies
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter.
Neighbor < IPv6 address> remote-as < as-number>	Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system.
Neighbor <IPv6 address> as-override	Enable BGP as-override for the specified neighbor.
Address-family ipv6	Enter address family configuration mode.
Neighbor < IPv6 address> activate	Exchange prefixes for the IPv6 router family between the specified neighbor and the NetScaler by using the link local address.
Neighbor <IPv6 address> as-override	Enable BGP as-override for the specified neighbor.

> VTYSH NS# configure terminal
NS(config)# router BGP 200
NS(config-router)# Neighbor a1bc::102 remote-as 100
NS(config-router)# Neighbor a1bc::102 as-override
NS(config-router)# Address-family ipv6
NS(config-router-af)# Neighbor a1bc::102 activate
NS(config-router)# Neighbor a1bc::102 as-override

To configure BGP AS-Override for IPv6 peer group by using the VTYSH command line

Command	Specifies
configure terminal	Enter global configuration mode.
router BGP < ASnumber>	BGP autonomous system. < ASnumber> is a required parameter.

Neighbor <peer group name> **peer-group**	Create a BGP peer group.
Neighbor <IPv6 address> **peer-group** <peer group name>	Associate a neighbor with the specified peer group.
Neighbor <peer group name> remote-as < as-number>	Update the IPv4 BGP neighbor table with the IPv4 address of the neighbor in the specified autonomous system.
Neighbor <peer group name> as-override	Enable BGP as-override for all the neighbors that are associated with the specified peer group.
Address-family ipv6	Enter address family configuration mode.
Neighbor <peer group name> activate	Exchange prefixes for the IPv6 router family between the neighbors of the specified peer group and the NetScaler by using the link local address.
Neighbor <peer group name> as-override	
	Enable BGP as-override for all the neighbors that are associated with the specified peer group.

```
> VTYSH NS# configure terminal
NS(config)# router BGP 200
NS(config-router)# neighbor external-peers-2 peer-group
NS(config-router)# neighbor 2001::1 peer-group external-peers-2
NS(config-router)# neighbor 2001::2 peer-group external-peers-2
NS(config-router)# Neighbor external-peers-2 remote-as 100
NS(config-router)# Neighbor external-peers-2 as-override
NS(config-router)# Address-family ipv6
NS(config-router-af)# Neighbor external-peers-2 activate
NS(config-router)# Neighbor external-peers-2 as-override
```

Graceful Restart

In a non-INC high availability (HA) setup in which a routing protocol is configured, after a failover, routing protocols are converged and routes between the new primary node and the adjacent neighbor routers are learned. Route learning take some time to complete. During this time, forwarding of packets is delayed, network performance might get disrupted, and packets might get dropped.

Graceful restart enables an HA setup during a failover to direct its adjacent routers to not remove the old primary node's learned routes from their routing databases. Using the old primary node's routing information, the new primary node and the adjacent routers immediately start forwarding packets, without disrupting network performance.

Configuring Graceful Restart for BGP

To configure graceful restart for BGP by using the VTYSH command line, at the command prompt, type the following

commands, in the order shown:

Command	Example	Command Description
VTYSH	VTYSH	Enters VTYSH command prompt.
configure terminal	NS# configure terminal	Enters global configuration mode.
router-id <ID>	NS(config)# router-id 1.1.1.1	A router identifier for the NetScaler appliance. This identifier is set for all the dynamic routing protocols. The same identifier must be specified on the other node in a high availability setup for graceful restart to work properly.
router bgp <AS-number>	NS(config)# router bgp 1	Enters BGP configuration mode.
bgp graceful-restart	NS(config)# bgp graceful-restart	Enables graceful restart on the BGP routing process.
bgp graceful-restart restart-time <1-1800>	NS(config-router)# bgp graceful-restart restart-time 170	Specifies the grace period, in seconds, that the helper routers waits for a TCP connection from the new primary node after a failover. For this amount of time, the helper routers preserve the routes.
bgp graceful-restart stalepath-time <1-1800>	NS(config-router)# bgp graceful-restart stalepath-time 180	Specifies the time, in seconds, that the NetScaler appliance in helper mode retains the stale routes for restarting neighbor routers. The default value is 360 seconds.
neighbor <IPv4 address of the peer router> remote-as <AS-number>	NS(config-router)# neighbor 192.0.2.30 remote-as 2	Establishes BGP peering with the specified neighbor router device.
neighbor <IPv4 address of the peer router> capability graceful-restart	NS(config-router)# neighbor 192.0.2.30 capability graceful-restart	Enables graceful restart with the specified neighbor.
redistribute kernel	NS(config-router)# redistribute kernel	Redistributes kernel routes.

Configuring Graceful Restart for IPv6 BGP

In a non-INC high availability (HA) setup in which a routing protocol is configured, after a failover, routing protocols are converged and routes between the new primary node and the adjacent neighbor routers are learned. Route learning take some time to complete. During this time, forwarding of packets is delayed, network performance might get disrupted, and packets might get dropped.

Graceful restart enables an HA setup during a failover to direct its adjacent routers to not remove the old primary node's learned routes from their routing databases. Using the old primary node's routing information, the new primary node and the adjacent routers immediately start forwarding packets, without disrupting network performance.

To configure graceful restart for IPv6 BGP by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Example	Command Description
VTYSH	VTYSH	Enters VTYSH command prompt.
configure terminal	NS# configure terminal	Enters global configuration mode.
router-id <id>	NS(config)# router-id 1.1.1.1	Sets a router identifier for the NetScaler appliance. This identifier is set for all the dynamic routing protocols. The same ID must be specified in the other node in a high availability setup for graceful restart to work properly.
router bgp <AS-number>	NS(config)# router bgp 1	Enters configuration mode for BGP protocol.
bgp graceful-restart	NS(config)# bgp graceful-restart	Enables graceful restart on the BGP routing process.
bgp graceful-restart restart-time <1-1800>	NS(config-router)# bgp graceful-restart restart-time 170	Specifies the grace period, in seconds, that the helper routers waits for a TCP connection from the new primary node after a failover. For this amount of time, the helper routers preserve the routes. The default value is 360 seconds.
bgp graceful-restart stalepath-time <1-1800>	NS(config-router)# bgp graceful-restart stalepath-time 180	Specifies the time, in seconds, that the NetScaler appliance in helper mode retains the stale routes for restarting neighbor routers. The default value is 360 seconds.
neighbor <IPv6 address> remote-as <AS-number>	NS(config-router)# neighbor 2001:db8::10 remote-as 2	Establishes BGP peering with the specified neighbor router device.
address-family ipv6	NS(config-router)#address-family ipv6	Enters address family configuration mode.
neighbor <IPv6 address of the neighbor> activate	NS(config-router-af)#neighbor 2001:db8::10 activate	Enables the exchange of address family routes with the specified neighbor router device.
neighbor <IPv6 address of the neighbor> capability graceful-restart	NS(config-router-af)#neighbor 2001:db8::10 capability graceful-restart	Enables graceful restart with the specified neighbor router device.
redistribute kernel	NS(config-router-af)#redistribute kernel	Redistributes kernel routes.
exit-address-family	NS(config-router-af)#exit-address-family	Exits address family configuration mode.

Command	Example	Command Description

Configuring IPv6 RIP

Mar 20, 2012

IPv6 Routing Information Protocol (RIP) or RIPng is a Distance Vector protocol. This protocol is an extension of RIP to support IPv6. After enabling IPv6 RIP, you need to configure advertisement of IPv6 RIP routes. For troubleshooting, you can limit IPv6 RIP propagation. You can display IPv6 RIP settings to verify the configuration.

Prerequisites for IPv6 RIP

Before you begin configuring IPv6 RIP, do the following:

- Make sure that you understand the IPv6 RIP protocol.
- Install the IPv6PT license on the NetScaler appliance.
- Enable the IPv6 feature.

Advertising IPv6 RIP Routes

Updated: 2013-08-30

IPv6 RIP enables an upstream router to load balance traffic between two identical vservers hosted on two standalone NetScaler devices. Route advertisement enables an upstream router to track network entities located behind the NetScaler.

To configure IPv6 RIP to advertise IPv6 routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ipv6 rip	Start IPv6 RIP routing process and enter configuration mode for the routing process.
redistribute static	Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router ipv6 rip
NS(config-router)# redistribute static
NS(config-router)# redistribute kernel
```

Limiting IPv6 RIP Propagations

Updated: 2013-08-30

If you need to troubleshoot your configuration, you can configure the listen-only mode on any given interface.

To limit IPv6 RIP propagation by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ipv6 rip	Start IPv6 RIP routing process and enter configuration mode for the routing process.
passive-interface < vlan_name>	Suppress routing updates on interfaces bound to the specified VLAN.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router ipv6 rip
NS(config-router)# passive-interface VLAN0
```

Verifying the IPv6 RIP Configuration

Updated: 2013-08-30

You can use VTYSH to display the IPv6 RIP routing table and IPv6 RIP information for a specified VLAN.

To view the IPv6 RIP settings by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
sh ipv6 rip	Display updated IPv6 RIP routing table.
sh ipv6 rip interface <vlan_name>	Display IPv6 RIP information for the specified VLAN.

Example

```
NS# VTYSH
NS# sh ipv6 rip
NS# sh ipv6 rip interface VLAN0
```

Configuring IPv6 OSPF

Jul 07, 2016

IPv6 OSPF or OSPF version 3 (OSPF v3) is a link state protocol that is used to exchange IPv6 routing information. After enabling IPv6 OSPF, you need to configure advertisement of IPv6 OSPF routes. For troubleshooting, you can limit IPv6 OSPF propagation. You can display IPv6 OSPF settings to verify the configuration.

Prerequisites for IPv6 OSPF

Before you begin configuring IPv6 OSPF, do the following:

- Make sure that you understand the IPv6 OSPF protocol.
- Install the IPv6PT license on the NetScaler appliance.
- Enable the IPv6 feature.

Advertising IPv6 Routes

Updated: 2013-08-30

IPv6 OSPF enables an upstream router to load balance traffic between two identical vservers hosted on two standalone NetScaler devices. Route advertising enables an upstream router to track network entities located behind the NetScaler.

To configure IPv6 OSPF to advertise IPv6 routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ipv6 OSPF	Start IPv6 OSPF routing process and enter configuration mode for the routing process.
redistribute static	Redistribute static routes.
redistribute kernel	Redistribute kernel routes.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router ipv6 OSPF
NS(config-router)# redistribute static
NS(config-router)# redistribute kernel
```

Limiting IPv6 OSPF Propagations

Updated: 2013-08-30

If you need to troubleshoot your configuration, you use VTYSH to configure listen-only mode on any given VLAN.

To limit IPv6 OSPF propagation by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ipv6 OSPF	Start IPv6 OSPF routing process and enter configuration mode for the routing process.
passive-interface < vlan_name >	Suppress routing updates on interfaces bound to the specified VLAN.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router ipv6 OSPF
NS(config-router)# passive-interface VLAN0
```

Verifying the IPv6 OSPF Configuration

Updated: 2013-08-30

You use VTYSH to display IPv6 OSPF current neighbors and IPv6 OSPF routes.

To view the IPv6 OSPF settings by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
sh ipv6 OSPF neighbor	Display current neighbors.
sh ipv6 OSPF route	Display IPv6 OSPF routes.

Example

```
>VTYSH
NS# sh ipv6 OSPF neighbor
NS# sh ipv6 OSPF route
```

OSPFv3 Authentication

Updated: 2015-06-15

To ensure the integrity, data origin authentication, and data confidentiality of OSPFv3 packets, OSPFv3 authentication must be configured on OSPFv3 peers.

The NetScaler appliance supports OSPFv3 authentication and is partially compliant with RFC 4552. OSPFv3 authentication is based on the two IPSec protocols: Authentication Header (AH) and Encapsulating Security Payload (ESP). The NetScaler appliance supports only the AH protocol for OSPFv3 authentication.

OSPFv3 authentication uses manually defined IPSec Security Associations (SAs) between the OSPFv3 peers and does not rely on IKE protocol for forming dynamic SAs. Manual SAs define the security parameter Index (SPI) values, algorithms, and keys to be used between the peers. Manual SAs require no negotiation between the peers; therefore, the same SA must be defined on both the peers.

You can configure OSPFv3 authentication on a VLAN or for an OSPFv3 area. When you configure for a VLAN, the settings are applied to all the interfaces that are members of the VLAN. When you configure OSPFv3 authentication for an OSPF area, the settings are applied to all the VLANs in that area. The settings are in turn applied to all the interfaces that are members of these VLANs. These settings do not apply to member VLANs on which you have configured OSPFv3 authentication directly.

Consider the following points and limitations before configuring OSPFv3 authentication on a NetScaler appliance:

- Make sure that you understand the different components of OSPFv3 authentication, described in RFC 4552.
- Only Authentication Header protocol is supported for OSPFv3 authentication. Encapsulating Security Payload (ESP) is not supported.
- You must define an SA with the same setting on the peer interface.
- Rekeying of manual keys is not supported.

To configure OSPFv3 authentication on a VLAN by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display the VTYSH command prompt.
configure terminal	Enter global configuration mode.
interface < vlan_name>	Enter the VLAN configuration mode.

ipv6 ospf authentication ipsec spi <spi> [**MD5**|**SHA1**] <string>	Set the following OSPFv3 authentication parameters.
	• **SPI**—Configures the Security Parameter Index (SPI) for the manual IPSec SA. Possible values: 256 to 4294967295.
	• **Authentication Algorithms and Key**—MD5 or SHA1 algorithms are used by the AH protocol for OSPFv3 authentication between the OSPFv3 peers. The string specifies the key for the selected authentication algorithm:
	  • An MD5 key specifies a 32-character or 16-byte hexadecimal string.
	  • A SHA1 key specifies a 40-character or 20-byte hexadecimal string.

Example

> VTYSH NS# configure terminal
NS(config)# interface vlan2
NS(config-if)# ipv6 ospf authentication ipsec spi 256 md5 123456789ABCDEF0123456789ABCDEF0

To configure OSPFv3 authentication on an OSPF area by using the VTYSH command line:

At the command prompt, type the following commands, in the order shown:

Command	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
router ipv6 ospf <process tag>	Enter IPv6 OSPF configuration mode.

area <areaid> **authentication ipsec spi** <spi> [**MD5**|**SHA1**] <string>	Set the following OSPFv3 authentication parameters for the specified OSPF area.
	• **SPI**— Configures the Security Parameter Index (SPI) for the manual IPSec SA. Possible values: 256 to 4294967295.
	• **Authentication Algorithms and Key**— MD5 or SHA1 algorithms are used by the AH protocol for OSPFv3 authentication between the OSPFv3 peers. The string specifies the key for the selected authentication algorithm:
	  • An MD5 key specifies a 32-character or 16-byte hexadecimal string.
	  • A SHA1 key specifies a 40-character or 20-byte hexadecimal string.

Example

> VTYSH NS# configure terminal
ns(config)#router ipv6 ospf 30
ns(config-router)# area 1 authentication ipsec spi 256 md5123456789ABCDEF0123456789ABCDEF0

Configuring Graceful Restart for IPv6 OSPF

In a non-INC high availability (HA) setup in which a routing protocol is configured, after a failover, routing protocols are converged and routes between the new primary node and the adjacent neighbor routers are learned. Route learning take some time to complete. During this time, forwarding of packets is delayed, network performance might get disrupted, and packets might get dropped.

Graceful restart enables an HA setup during a failover to direct its adjacent routers to not remove the old primary node's learned routes from their routing databases. Using the old primary node's routing information, the new primary node and the adjacent routers immediately start forwarding packets, without disrupting network performance.

To configure graceful restart for IPv6 OSPF by using the VTYSH command line, at the command prompt, type the following commands, in the order shown:

Command	Example	Command Description
VTYSH	> VTYSH	Enters VTYSH command prompt.
configure terminal	NS# configure terminal	Enters global configuration mode.
router-id id>	NS(config)# router-id 1.1.1.1	Sets a router identifier for the NetScaler appliance. This identifier is set for all the dynamic routing protocols. The same ID must be specified in the other node in a high availability set up for graceful restart to work properly in the HA set up.
IPv6 ospf restart grace-period <1-1800>	NS(config)# IPv6 ospf restart grace-period 170	Specifies the grace period, in seconds, for which the routes are to be preserved in the helper devices. Default value: 120 seconds.
IPv6 ospf restart helper max-grace-period <1-1800>	NS(config)# IPv6 ospf restart helper max-grace-period 180	This is an optional command to limit the maximum grace period for which the NetScaler appliance will be in the helper mode. If the NetScaler appliance receives an opaque LSA with grace-period greater than the set helper max-grace-period, the LSA is discarded and the NetScaler is not placed in helper mode.
interface <VLANID>	NS(config)# interface vlan3	Enters VLAN configuration mode.
ipv6 router ospf area <area_id> tag <tag_id>	NS(config-if)#ipv6 router ospf area 0 tag 1	Starts IPv6 OSPF routing process on a VLAN.
exit	NS(config-if)#exit	Exits VLAN configuration mode.
router ipv6 ospf	NS(config)# router ipv6 ospf 1	Starts IPv6 OSPF routing process and enters configuration mode for the routing process.
capability restart graceful	NS(config-router)# capability restart graceful	Enables graceful restart on the IPv6 OSPF routing process.
redistribute kernel	NS(config-router)# redistribute kernel	Redistributes kernel routes.

Configuring ISIS

Mar 02, 2015

The NetScaler appliance supports the Intermediate System-to-Intermediate System (IS-IS or ISIS) dynamic routing protocol. This protocol supports IPv4 as well as IPv6 route exchanges. IS-IS is a link state protocol and is therefore less prone to routing loops. With the advantages of faster convergence and the ability to support larger networks, ISIS can be very useful in Internet Service Provider (ISP) networks.

Prerequisites for configuring ISIS

Before you begin configuring ISIS, do the following:

- Make sure that you understand the ISIS protocol.
- For IPV6 routes, enable:
  - IPv6 protocol translation feature.
  - IPv6 Dynamic Routing option on the VLANs on which you want to run ISIS protocol.

Enabling ISIS

Updated: 2013-08-30

Use either of the following procedures to enable the ISIS routing feature on the NetScaler appliance.

To enable ISIS routing by using the command line interface

At the command prompt, type:

```
enable ns feature ISIS
```

To enable ISIS routing by using the configuration utility

1. Navigate to System > Settings, in Modes and Features group, click Change advanced features.
2. Select or clear the ISIS Routing option.

Creating an ISIS Routing Process and Starting It on a VLAN

Updated: 2013-08-30

To create an ISIS routing process, you must use the VTYSH command line.

At the command prompt, type the following commands, in the order shown:

Command	Description
VTYSH	Displays VTYSH command prompt.
configure terminal	Enters the global configuration mode.
router ISIS [tag]	Creates an ISIS routing process and configuration mode for the routing process.
net XX....XXXX.YYYY.YYYY.YYYY.00	Specifies a NET value for the routing process, where: · XX. .. .XXXX is the Area Address (can be 1-13 bytes)

Command	Description
	· YYYY.YYYY.YYYY is the System ID (6 bytes) · 00 is the N-selector (1 byte) A NET value can be 8 to 20 bytes in length. The last byte is always the n-selector, and must be zero. The n-selector indicates that there is no transport entity and means that the packet is for the routing software of the appliance. The six bytes directly preceding the n-selector are the system ID. The system ID length is fixed and cannot be changed. The system ID must be unique throughout each area (Level 1) and throughout the backbone (Level 2). The bytes preceding the system ID are the area ID, which can be from 1 to 13 bytes in length. A maximum of three NETs per routing process are allowed with different area ID, but the system ID should be the same for all NETs.
is-type (level-1|level-1-2|level-2-only)	Sets the ISIS routing process to the specified level of routing. Default: level-1-2.
ns IPv6-routing	Starts the IPv6 dynamic routing daemon.
interface <vlan_name>	Enters the VLAN configuration mode.
ip router ISIS	Enables the ISIS routing process on the VLAN for IPv4 route exchanges.
ipv6 router ISIS	Enables the ISIS routing process on the VLAN for IPv6 route exchanges.

Example

```
> VTYSH
NS# configure terminal
NS(config)# router isis 11
NS(config-router)# net 15.aabb.ccdd.0097.00
NS(config-router)# is-type level-1
NS(config-router)# exit
NS(config)# ns IPv6-routing
NS(config)# interface vlan0
NS(config-if)#  ip router isis 11
NS(config-if)# ipv6 router isis 11
```

Advertising Routes

Updated: 2013-08-30

Route advertisement enables an upstream router to track network entities located behind the NetScaler appliance.

To configure ISIS to advertise routes by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Description
VTYSH	Displays the VTYSH command prompt.
configure terminal	Enters the global configuration mode.
router ISIS [tag]	Starts the ISIS routing instance and enter configuration mode for the

Command	Description
	routing process.
redistribute connected (level-1 | level-1-2 | level-2)	Redistributes connected routes, where • **level-1** : Redistribute connected routes into Level-1. • **level-1-2** : Redistribute connected routes into Level-1 and Level-2. • **level-2** : Redistribute connected routes into Level-2.
redistribute kernel(level-1 | level-1-2 | level-2)	Redistributes kernel routes, where: • **level-1** : Redistribute kernel routes into Level-1. • **level-1-2** : Redistribute kernel routes into Level-1 and Level-2. • **level-2** : Redistribute kernel routes into Level-2.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router isis 11
NS(config-router)# redistribute connected level-1
NS(config-router)# redistribute kernel level-1
```

Limiting ISIS Propagations

Updated: 2013-08-30

If you need to troubleshoot your configuration, you can configure the listen-only mode on any given VLAN.

To limit ISIS propagation by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Command	Description
VTYSH	Displays the VTYSH command prompt.
configure terminal	Enters the global configuration mode.
router isis [tag]	Enters the configuration mode for the routing process.
passive-interface <vlan_name>	Suppresses routing updates on interfaces bound to the specified VLAN.

Example

```
>VTYSH
NS# configure terminal
NS(config)# router isis 11
NS(config-router)# passive-interface VLAN0
```

Verifying the ISIS Configuration

Updated: 2013-08-30

You can use VTYSH to display the ISIS routing table and ISIS information for a specified VLAN.

To view the ISIS settings by using the VTYSH command line

At the command prompt, type the following commands, in the order shown:

Commands	Description
VTYSH	Displays the VTYSH command prompt.
show ip isis route	Displays updated IPv4 ISIS routing table.
show ipv6 isis route	Displays updated IPv6 ISIS routing table.
sh isis interface <vlan_name>	Displays IPv6 ISIS information for the specified VLAN.

Example

```
NS# VTYSH
NS#  show ip isis route
NS#  show ipv6 isis route
NS# sh isis interface VLAN0
```

Installing Routes to the NetScaler Routing Table

Aug 30, 2013

The NetScaler appliance can use routes learned by various routing protocols after you install the routes in the appliance's routing table.

To install various routes to the internal routing table by using the VTYSH command line

At the command prompt, type the following commands as appropriate for the routes that you want to install:

Commands	Specifies
VTYSH	Display VTYSH command prompt.
configure terminal	Enter global configuration mode.
ns route-install Default	Install IPv4 default routes to the internal routing table.
ns route-install RIP	Install IPv4 RIP specific routes to the internal routing table.
ns route-install BGP	Install IPv4 BGP specific routes to the internal routing table.
ns route-install OSPF	Install IPv4 OSPF specific routes to the internal routing table.
ns route-install IPv6 Default	Install IPv6 default routes to the internal routing table.
ns route-install IPv6 RIP	Install IPv6 RIP specific routes to the internal routing table.
ns route-install IPv6 BGP	Install IPv6 BGP specific routes to the internal routing table.
ns route-install IPv6 OSPF	Install IPv6 OSPF specific routes to the internal routing table.

Example

```
>VTYSH
NS# configure terminal
NS# ns route-install Default
NS(config)# ns route-install RIP
NS(config)# ns route-install BGP
NS(config)# ns route-install OSPF
NS# ns route-install IPv6 Default
NS(config)# ns route-install IPv6 RIP
NS(config)# ns route-install IPv6 BGP
NS(config)# ns route-install IPv6 OSPF
```

Advertisement of SNIP and VIP Routes to Selective Areas

Jan 17, 2017

To advertise some SNIP addresses to selective areas, enabling DRADV mode or redistribute connect ZebOS operations cannot be used. This is because these operations send all the connected routes to ZebOS. Also, adding dummy static routes in ZebOS for the required subnets, or adding ACLs in ZebOS to filter unwanted connected routes, is a cumbersome and tedious task.

The Network Route and the Tag options address this issue. You can enable the Network Route option for only one SNIP address per subnet. The connected route for that SNIP address is sent as a kernel route to ZebOS.

For VIP and SNIP addresses, Tag, can be assigned an integer from 1 to 4294967295. This parameter can be set only when Host Route or Network Route is enabled for VIP or SNIP addresses. The tag value associated with VIP and SNIP addresses are also sent along with their routes to ZebOS. Tags with different values can be set for VIP and SNIP routes. These tag values can then be matched in route maps in ZebOS and advertised to selective areas.

To configure the network route and tag parameters of a SNIP address by using the command line interface

At the command prompt, type one of the following sets of commands.

If adding a new SNIP address:

- **add ns ip** <IPAddress>@ <netmask> -**type SNIP** -**networkroute** (**ENABLED** | **DISABLED**) -**tag** <positive_integer>
- **show ns ip** <IPAddress>

If reconfiguring an existing SNIP address:

- **set ns ip** <IPAddress>@ <netmask> -**type SNIP** - **networkroute** (**ENABLED** | **DISABLED**) -**tag** <positive_integer>
- **show ns ip** <IPAddress>

To configure the host route and tag parameters of a VIP address by using the command line interface

At the command prompt, type one of the following sets of commands.

If adding a new VIP address:

- **add ns ip** <IPAddress>@ <netmask> -**type VIP** -**hostRoute** (**ENABLED** | **DISABLED**) -**tag** <positive_integer>
- **show ns ip** <IPAddress>

If reconfiguring an existing VIP address:

- **set ns ip** <IPAddress>@ <netmask> -**type VIP** -**hostRoute** (**ENABLED** | **DISABLED**) -**tag** <positive_integer>
- **show ns ip** <IPAddress>

Configuring Static Routes

Feb 13, 2017

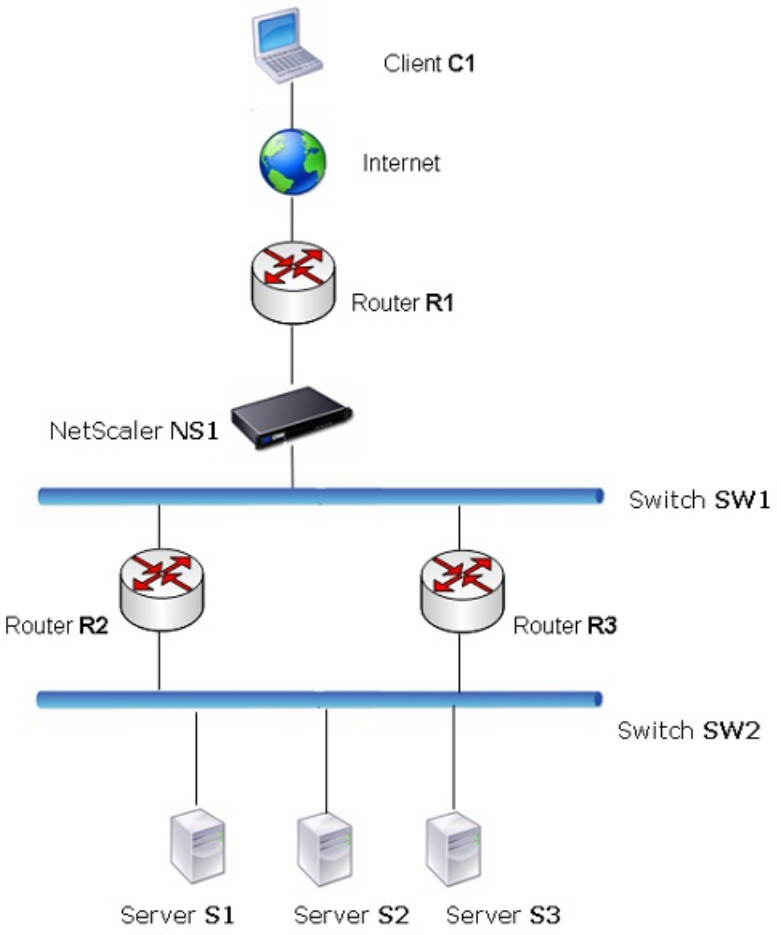
Static routes are manually created to improve the performance of your network. You can monitor static routes to avoid service disruptions. Also, you can assign weights to ECMP routes, and you can create null routes to prevent routing loops.

Monitored Static Routes

If a manually created (static) route goes down, a backup route is not automatically activated. You must manually delete the inactive primary static route. However, if you configure the static route as a monitored route, the NetScaler appliance can automatically activate a backup route.

Static route monitoring can also be based on the accessibility of the subnet. A subnet is usually connected to a single interface, but it can be logically accessed through other interfaces. Subnets bound to a VLAN are accessible only if the VLAN is up. VLANs are logical interfaces through which packets are transmitted and received by the NetScaler. A static route is marked as DOWN if the next hop resides on a subnet that is unreachable.

Note: In a high availability (HA) setup, the default value for monitored state routes (MSRs) on the secondary node is UP. The value is set to avoid a state transition gap upon failover, which could result in dropping packets on those routes.
Consider the following simple topology, in which a NetScaler is load balancing traffic to a site across multiple servers.



Router R1 moves traffic between the client and the NetScaler appliance. The appliance can reach servers S1 and S2 through routers R2 or R3. It has two static routes through which to reach the servers' subnet, one with R2 as the gateway and another with R3 as the gateway. Both these routes have monitoring enabled. The administrative distance of the static route with gateway R2 is lower than that of the static route with gateway R3. Therefore, R2 is preferred over R3 to forward traffic to the servers. Also, the default route on the NetScaler points to R1 so that all Internet traffic exits properly.

If R2 fails while monitoring is enabled on the static route, which uses R2 as the gateway, the NetScaler marks it as DOWN. The NetScaler now uses the static route with R3 as the gateway and forwards the traffic to the servers through R3.

The NetScaler supports monitoring of IPv4 and IPv6 static routes. You can configure the NetScaler to monitor an IPv4 static route either by creating a new ARP or PING monitor or by using existing ARP or PING monitors. You can configure the NetScaler to monitor an IPv6 static route either by creating a new Neighbor discovery for IPv6 (ND6) or PING monitor or by using the existing ND6 or PING monitors.

Weighted Static Routes

When the NetScaler appliance makes routing decisions involving routes with equal distance and cost, that is, Equal Cost Multi-Path (ECMP) routes, it balances the load between them by using a hashing mechanism based on the source and destination IP addresses. For an ECMP route, however, you can configure a weight value. The NetScaler then uses both the weight and the hashed value for balancing the load.

Null Routes

If the route chosen in a routing decision is inactive, the NetScaler appliance chooses a backup route. If all the backup routes become inaccessible, the appliance might reroute the packet to the sender, which could result in a routing loop leading to network congestion. To prevent this situation, you can create a null route, which adds a null interface as a gateway. The null route is never the preferred route, because it has a higher administrative distance than the other static routes. But it is selected if the other static routes become inaccessible. In that case, the appliance drops the packet and prevents a routing loop.

This section includes the following details:

- Configuring IPv4 Static Routes
- Configuring IPv6 Static Routes

Configuring IPv4 Static Routes

Updated: 2013-09-06

You can add a simple static route or a null route by setting a few parameters, or you can set additional parameters to configure a monitored or monitored and weighted static route. You can change the parameters of a static route. For example, you might want to assign a weight to an unweighted route, or you might want to disable monitoring on a monitored route.

To create a static route by using the command line interface

At the command prompt, type the following commands to create a static route and verify the configuration:

- add route <network> <netmask> <gateway>[-cost <positive_integer>] [-advertise (DISABLED | ENABLED)]
- show route [<network> <netmask> [<gateway>]] [<routeType>] [-detail]

Example

```
> add route 10.102.29.0 255.255.255.0 10.102.29.2 -cost 2 -advertise ENABLED
 Done
```

To create a monitored static route by using the command line interface

At the command prompt, type the following commands to create a monitored static route and verify the configuration:

- add route <network> <netmask> <gateway> [-distance <positive_integer>] [-weight <positive_integer>][-msr (ENABLED | DISABLED) [-monitor <string>]]
- show route [<network> <netmask> [<gateway>]] [<routeType>] [-detail]

Example

```
> add route 10.102.29.0 255.255.255.0 10.102.29.3 -distance 5 -weight 6 -msr ENBLED -monitor PING
 Done
```

To create a null route by using the command line interface

At the command prompt type:

- add route <network> <netmask> null
- show route <network> <netmask>

Example

```
> add route 10.102.29.0 255.255.255.0 null
 Done
```

To remove a static route by using the command line interface

At the command prompt, type:

rm route <network> <netmask> <gateway>

Example

```
> rm route 10.102.29.0 255.255.255.0 10.102.29.3
 Done
```

To configure a static route by using the configuration utility

Navigate to System > Network > Routes and, on the Basic tab, add a new static route, or edit an existing static route.

To remove a route by using the configuration utility

Navigate to System > Network > Routes and, on the Basic tab, delete the static route.

Configuring IPv6 Static Routes

Updated: 2013-09-06

You can configure a maximum of six default IPv6 static routes. IPv6 routes are selected on the basis of whether the MAC address of the destination device is reachable. This can be determined by using the IPv6 Neighbor Discovery feature. Routes are load balanced and only source/destination-based hash mechanisms are used. Therefore, route selection mechanisms such as round robin are not supported. The next hop address in the default route need not belong to the NSIP subnet.

To create an IPv6 route by using the command line interface

At the command prompt, type the following commands to create an IPv6 route and verify the configuration:

- add route6 <network> <gateway> [-vlan <positive_integer>]
- show route6 [<network> [<gateway>]

Example

```
> add route6 ::/0 FE80::67 -vlan 5
 Done
```

To create a monitored IPv6 static route by using the command line interface

At the command prompt, type the following commands to create a monitored IPv6 static route and verify the

configuration:

- add route6 <network> <gateway> [-msr (ENABLED | DISABLED) [-monitor <string>]
- show route6 [<network> [<gateway>]

Example

```
> add route6 ::/0 2004::1 -msr ENABLED -monitor PING
 Done
```

To remove an IPv6 route by using the command line interface

At the command prompt, type:

rm route6 <network> <gateway>

Example

```
> rm route6 ::/0 FE80::67
 Done
```

To configure an IPv6 route by using the configuration utility

Navigate to System > Network > Routes and, on the IPV6 tab, add a new IPv6 route, or edit an existing IPv6 route.

To remove an IPv6 route by using the configuration utility

Navigate to System > Network > Routes and, on the IPV6 tab, delete the IPv6 route.

Route Health Injection Based on Virtual Server Settings

Apr 11, 2014

The following option and parameter are introduced for controlling the Route Health Injection (RHI) functionality of the NetScaler appliance for advertising the route of a VIP address.

- **VSVR_CNTRLD**. It is an option for the (Vserver RHI Level) parameter of a VIP address. When this option is set to the Vserver RHI Level parameter, the RHI behavior for advertising the route of the VIP address depends on the RHI STATE parameter setting on all the associated virtual servers of the VIP address along with their states.
- **RHI STATE**. It is a parameter of virtual server. You can set the RHI STATE parameter to either PASSIVE or ACTIVE. By default, the RHI STATE parameter is set to PASSIVE.

For a VIP address, when RHI (Vserver RHI Level) parameter is set to VSVR_CNTRLD, the following are different RHI behaviours for the VIP address on the basis of RHI STATE settings on the virtual servers associated with the VIP address:

- If you set RHI STATE to PASSIVE on all virtual servers, the NetScaler ADC always advertises the route for the VIP address.
- If you set RHI STATE to ACTIVE on all virtual servers, the NetScaler ADC advertises the route for the VIP address if at least one of the associated virtual servers is in UP state.
- If you set RHI STATE to ACTIVE on some and PASSIVE on others, the NetScaler ADC advertises the route for the VIP address if at least one of the associated virtual servers, whose RHI STATE set to ACTIVE, is in UP state.

Following table displays the sample RHI behaviour for a VIP address on the basis of RHI STATE settings on the virtual servers associated with the VIP address. The NetScaler appliance has two virtual servers V1 and V2 associated with the VIP address:

Associated virtual servers for a VIP	**State 1**	**State 2**	**State 3**	**State 4**
RHI State set to PASSIVE on all virtual servers				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Advertise the route for this VIP address?	Yes	Yes	Yes	Yes
RHI State set to ACTIVE on all virtual servers				
V1	UP	UP	DOWN	DOWN
V2	UP	DOWN	UP	DOWN
Advertise the route for this VIP address?	Yes	Yes	Yes	No
RHI State set to ACTIVE on one virtual server and PASSIVE on the other				
V1 (RHI State = ACTIVE)	UP	UP	DOWN	DOWN
V2 (RHI State = PASSIVE)	UP	DOWN	UP	DOWN

Associated virtual servers for a VIP	State 1	State 2	State 3	State 4
Advertise the route for this VIP address?	Yes	Yes	No	No

To configure RHI for a VIP address, to be based on the RHI (RHI State) parameter setting of the associated virtual servers, perform the following steps:

- Set the RHI (Vserver RHI Level) parameter to VSVR_CNTRLD for the VIP address.
- Set the RHI State parameter for each virtual server associated with the VIP address.

To set the vServer RHI Level for a VIP address by using command line interface

At the command prompt, type:

- set ns ip <IPAddress> [-vserverRHILevel <vserverRHILevel>]

To set the RHI State parameter of a virtual server by using command line interface

At the command prompt, type:

- set lb vserver <name> [-RHIstate (PASSIVE | ACTIVE)]

To set the vServer RHI Level for a VIP address by using configuration utility

1. Navigate to System > Network > IPs.
2. Select a VIP address, and then click Edit.
3. Set the Vserver RHI Level parameter to VSVR_CNTRLD, and then click OK.

To set the RHI State parameter of a virtual server by using configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Select a load balancing virtual server, and then click Edit.
3. Set the RHI State parameter, and then click OK.

Configuring Policy-Based Routes

Jun 11, 2012

Policy-based routing bases routing decisions on criteria that you specify. A policy-based route (PBR) specifies criteria for selecting packets and, typically, a next hop to which to send the selected packets. For example, you can configure the NetScaler appliance to route outgoing packets from a specific IP address or range to a particular next hop router. Each packet is matched against each configured PBR, in the order determined by the specified priorities, until a match is found. If no match is found, or if the matching PBR specifies a DENY action, the NetScaler applies the routing table for normal destination-based routing.

A PBR bases routing decisions for the data packets on parameters such as source IP address, source port, destination IP address, destination port, protocol, and source MAC address. A PBR defines the conditions that a packet must satisfy for the NetScaler to route the packet. These actions are known as "processing modes." The processing modes are:

- ALLOW - The NetScaler sends the packet to the designated next-hop router.
- DENY - The NetScaler applies the routing table for normal destination-based routing.

You can create PBRs for outgoing IPv4 and IPv6 traffic.

Many users begin by creating PBRs and then modifying them. To activate a new PBR, you must apply it. To deactivate a PBR, you can either remove or disable it. You can change the priority number of a PBR to give it a higher or lower precedence.

This document includes the following information:

- Configuring a Policy-Based Routes (PBR) for IPv4 Traffic
- Configuring a Policy-Based Routes (PBR6) for IPv6 Traffic

Configuring a Policy-Based Routes (PBR) for IPv4 Traffic

Mar 20, 2012

Configuring PBRs involves the following tasks:

- Create a PBR.
- Apply PBRs.
- (Optional) Disable or enable a PBR.
- (Optional) Renumber the priority of the PBR.

Creating or Modifying a PBR

Updated: 2013-10-31

You cannot create two PBRs with the same parameters. If you attempt to create a duplicate, an error message appears.

You can configure the priority of a PBR. The priority (an integer value) defines the order in which the NetScaler appliance evaluates PBRs. When you create a PBR without specifying a priority, the NetScaler automatically assigns a priority that is a multiple of 10.

If a packet matches the condition defined by the PBR, the NetScaler performs an action. If the packet does not match the condition defined by the PBR, the NetScaler compares the packet against the PBR with the next highest priority.

Instead of sending the selected packets to a next hop router, you can configure the PBR to send them to a link load balancing virtual server to which you have bound multiple next hops. This configuration can provide a backup if a next hop link fails.

Consider the following example. Two PBRs, p1 and p2, are configured on the NetScaler and automatically assigned priorities 20 and 30. You need to add a third PBR, p3, to be evaluated immediately after the first PBR, p1. The new PBR, p3, must have a priority between 20 and 30. In this case, you can specify the priority as 25.

To create a PBR by using the command line interface

At the command prompt, type:

- add ns pbr <name> <action> [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] [-nextHop <nextHopVal>] [-srcMac <mac_addr>] [-protocol <protocol> | -protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-msr (ENABLED | DISABLED) [-monitor <string>]] [-state (ENABLED | DISABLED)]
- show ns pbr

Example

```
> add ns pbr pbr1  allow -srcip 10.102.37.252 -destip 10.10.10.2 -nexthop 10.102.29.77
 Done
```

To modify the priority of a PBR by using the command line interface

At the command prompt, type the following commands to modify the priority and verify the configuration:

- set ns pbr <name> [-action (ALLOW | DENY)] [-srcIP [<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [-destIP [<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>] [-nextHop <nextHopVal>] [-srcMac <mac_addr>] [-protocol <protocol> | -protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-msr (ENABLED | DISABLED) [-monitor <string>]] [-state (ENABLED | DISABLED)]
- show ns pbr [<name>]

Example

```
> set ns pbr pbr1 -priority 23
 Done
```

To remove one or all PBRs by using the command line interface

At the command prompt, type one of the following commands:

- rm ns pbr <name>
- clear ns pbrs

Example

```
> rm ns pbr pbr1
 Done
> clear ns PBRs
 Done
```

To create a PBR by using the configuration utility

Navigate to System > Network > PBRs, on the PBRs tab, add a new PBR, or edit an existing PBR.

To remove one or all PBRs by using the configuration utility

Navigate to System > Network > PBRs, on the PBRs tab, delete the PBR.

Applying a PBR

Updated: 2013-08-30

You must apply a PBR to activate it. The following procedure reapplies all PBRs that you have not disabled. The PBRs constitute a memory tree (lookup table). For example, if you create 10 PBRs (p1 - p10), and then you create another PBR (p11) and apply it, all of the PBRs (p1 - p11) are freshly applied and a new lookup table is created. If a session has a DENY PBR related to it, the session is destroyed.

You must apply this procedure after every modification you make to any PBR. For example, you must follow this procedure after disabling a PBR.

Note: PBRs created on the NetScaler appliance do not work until they are applied.

To apply a PBR by using the command line interface

At the command prompt, type:

apply ns PBRs

To apply a PBR by using the configuration utility

1. Navigate to System > Network > PBRs.
2. On the PBRs tab, select the PBR, in the Action list, select Apply.

Enabling or Disabling PBRs

Updated: 2013-08-30

By default, the PBRs are enabled. This means that when PBRs are applied, the NetScaler appliance automatically compares incoming packets against the configured PBRs. If a PBR is not required in the lookup table, but it needs to be retained in the configuration, it must be disabled before the PBRs are applied. After the PBRs are applied, the NetScaler does not compare incoming packets against disabled PBRs.

To enable or disable a PBR by using the command line interface

At the command prompt, type one of the following commands:

- enable ns pbr <name>
- disable ns pbr <name>

Examples

```
> enable ns PBR pbr1
 Done
> show ns PBR pbr1
1)    Name: pbr1
      Action: ALLOW                 Hits: 0
      srcIP = 10.102.37.252
      destIP = 10.10.10.2
      srcMac:                    Protocol:
      Vlan:                      Interface:
      Active Status: ENABLED          Applied Status: APPLIED
      Priority: 10
      NextHop: 10.102.29.77

 Done

> disable ns PBR pbr1
Warning: PBR modified, use 'apply pbrs' to commit this operation
> apply pbrs
 Done
> show ns PBR pbr1
1)    Name: pbr1
      Action: ALLOW                 Hits: 0
      srcIP = 10.102.37.252
```

```
    destIP = 10.10.10.2
    srcMac:                 Protocol:
    Vlan:                   Interface:
    Active Status: DISABLED         Applied Status: NOTAPPLIED
    Priority: 10
    NextHop: 10.102.29.77
Done
```

To enable or disable a PBR by using the configuration utility

1. Navigate to System > Network > PBRs.
2. On the PBRs tab, select the PBR, in the Action list, select Enable or Disable.

Renumbering PBRs

Updated: 2013-08-30

You can automatically renumber the PBRs to set their priorities to multiples of 10.

To renumber PBRs by using the command line interface

At the command prompt, type:

```
renumber ns pbrs
```

To renumber PBRs by using the configuration utility

Navigate to System > Network > PBRs, on the PBRs tab, in the Action list, select Renumber Priority (s).

Use Case - PBR with Multiple Hops

Updated: 2013-08-30

Consider a scenario in which two PBRs, PBR1 and PBR2, are configured on NetScaler appliance NS1. PBR1 routes all the outgoing packets, with source IP address as 10.102.29.30, to next hop router R1. PBR2 routes all the outgoing packets, with source IP address as 10.102.29.90, to next hop router R2. R3 is another next hop router connected to NS1.

If router R1 fails, all the outgoing packets that matched against PBR1 are dropped. To avoid this situation, you can specify a link load balancing (LLB) virtual server in the next hop field while creating or modifying a PBR. Multiple next hops are bound to the LLB virtual server as services (for example R1, R2, and R3). Now, if R1 fails, all the packets that matched against PBR1 are routed to R2 or R3 as determined by the LB method configured on the LLB virtual server.

The NetScaler appliance throws an error if you attempt to create a PBR with an LLB virtual server as the next hop in the following cases:

- Adding another PBR with the same LLB virtual server.
- Specifying a nonexistent LLB virtual server.
- Specifying an LLB virtual server for which the bound services are not next hops.
- Specifying an LLB virtual server for which the LB method is not set to one of the following:
  - LEASTPACKETS
  - LEASTBANDWIDTH
  - DESTIPHASH
  - SOURCEIPHASH

- WEIGHTDRR
- SRCIPDESTIP_HASH
- LTRM
- CUSTOM LOAD

- Specifying an LLB virtual server for which the LB persistence type is not set to one of the following:
  - DESTIP
  - SOURCEIP
  - SRCDSTIP

The following table lists the names and values of the entities configured on the NetScaler appliance:

Table 1. Sample Values for Creating Entities

Entity Type	Name	IP Address
Link load balancing virtual server	LLB1	NA
Services (next hops)	Router1	1.1.1.254
	Router2	2.2.2.254
	Router3	3.3.3.254
PBRs	PBR1	NA
	PBR2	NA

To implement the configuration described above, you need to:

1. Create services Router1, Router2, and Router3 that represent next hop routers R1, R2, and R3.
2. Create link load balancing virtual server LLB1 and bind services Router1, Router2, and Router3 to it.
3. Create PBRs PBR1 and PBR2, with next hop fields set as LLB1 and 2.2.2.254 (IP address of the router R2), respectively.

To create a service by using the command line interface

At the command prompt, type:

- add service <name> <IP> <serviceType> <port>
- show service <name>

Example

```
> add service Router1 1.1.1.254 ANY *
 Done
> add service Router2 2.2.2.254 ANY *
 Done
> add service Router3 3.3.3.254 ANY *
 Done
```

To create a service by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, and create a service.

To create a link load balancing virtual server and bind a service by using the command line interface

At the command prompt, type:

- add lb vserver <name> <serviceType>
- bind lb vserver < name> <serviceName>
- show lb vserver < name>

Example

```
> add lb vserver LLB1 ANY
 Done
> bind lb vserver LLB1 Router1 Router2 Router3
 Done
```

To create a link load balancing virtual server and bind a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and create a virtual server for link load balancing. Specify **ANY** in the **Protocol** field.
   Note: Make sure that **Directly Addressable** is unchecked.
2. Under the **Services** tab, in the **Active** column, select the check box for the service that you want to bind to the virtual server.

To create a PBR by using the command line interface

At the command prompt, type:

- add ns pbr <name> <action> [-srcIP [<operator>] <srcIPVal>] [-nextHop <nextHopVal>]
- show ns pbr

Example

```
> add pbr PBR1 ALLOW -srcIP 10.102.29.30 -nextHop LLB1
 Done
> add pbr PBR2 ALLOW -srcIP 10.102.29.90 -nextHop 2.2.2.254
 Done
```

To create a PBR by using the configuration utility

Navigate to System > Network > PBRs, on the PBRs tab, add a new PBR.

Configuring a Policy-Based Routes (PBR6) for IPv6 Traffic

Mar 20, 2012

Configuring PBR6s involves the following tasks:

- Create a PBR6.
- Apply PBR6s.
- (Optional) Disable or enable a PBR6.
- (Optional) Renumber the priority of the PBR6.

Creating or Modifying a PBR6

Updated: 2013-09-06

You cannot create two PBR6s with the same parameters. If you attempt to create a duplicate, an error message appears.

You can configure the priority of a PBR6. The priority (an integer value) defines the order in which the NetScaler appliance evaluates PBR6s. When you create a PBR6 without specifying a priority, the NetScaler automatically assigns a priority that is a multiple of 10.

If a packet matches the condition defined by the PBR6, the NetScaler performs an action. If the packet does not match the condition defined by the PBR6, the NetScaler compares the packet against the PBR6 with the next highest priority.

To create a PBR6 by using the command line interface

At the command prompt, type:

- add ns pbr6 <name> <action> [-srcIPv6 [<operator>] <srcIPv6Val>] [-srcPort [<operator>] <srcPortVal>] [-destIPv6 [<operator>] <destIPv6Val>] [-destPort [<operator>] <destPortVal>] [-srcMac <mac_addr>] [-protocol <protocol> |-protocolNumber <positive_integer>] [-vlan <positive_integer>] [-interface <interface_name>] [-priority <positive_integer>] [-state (ENABLED | DISABLED)] [-msr (ENABLED | DISABLED) [-monitor <string>]] [-nextHop <nextHopVal>] [-nextHopVlan <positive_integer>]
- show ns pbr

To modify or remove a PBR6 by using the command line interface

To modify a PBR6, type the set pbr6 <name> command and the parameters to be changed, with their new values.

To remove one or all PBR6s by using the command line interface

At the command prompt, type one of the following commands:

- rm ns pbr6 <name>
- clear ns pbr6

To create or modify a PBR6 by using the configuration utility

Navigate to System > Network > PBRs and, on the PBR6s tab, add a new PBR6, or edit an existing PBR6.

To remove one or all PBR6s by using the configuration utility

Navigate to System > Network > PBRs and, on the PBR6s tab, delete the PBR6.

Applying PBR6s

Updated: 2013-08-30

You must apply a PBR6 to activate it. The following procedure reapplies all PBR6s that you have not disabled. The PBR6s constitute a memory tree (lookup table). For example, if you create 10 PBR6s (p6_1 - p6_10), and then you create another PBR6 (p6_11) and apply it, all of the PBR6s (p6_1 - p6_11) are freshly applied and a new lookup table is created. If a session has a DENY PBR6 related to it, the session is destroyed.

You must apply this procedure after every modification you make to any PBR6. For example, you must follow this procedure after disabling a PBR6.

Note: PBR6s created on the NetScaler appliance do not work until they are applied.

To apply PBR6s by using the command line interface

At the command prompt, type:

apply ns PBR6

To apply PBR6s by using the configuration utility

1. Navigate to System > Network > PBRs.
2. On the PBR6s tab, select the PBR6, in the Action list, select Apply.

Enabling or Disabling a PBR6

Updated: 2013-08-30

By default, the PBR6s are enabled. This means that when PBR6s are applied, the NetScaler appliance automatically compares outgoing IPv6 packets against the configured PBR6s. If a PBR6 is not required in the lookup table, but it needs to be retained in the configuration, it must be disabled before the PBR6s are applied. After the PBR6s are applied, the NetScaler does not compare incoming packets against disabled PBR6s.

To enable or disable a PBR6 by using the command line interface

At the command prompt, type one of the following commands:

- enable ns pbr <name>
- disable ns pbr <name>

To enable or disable a PBR6 by using the configuration utility

1. Navigate to System > Network > PBRs.
2. On the PBR6s tab, select the PBR6, in the Action list, select Enable or Disable.

Renumbering PBR6s

Updated: 2013-08-30

You can automatically renumber the PBR6s to set their priorities to multiples of 10.

To renumber PBR6s by using the command line interface

At the command prompt, type:

renumber ns pbr6

To renumber PBR6s by using the configuration utility

Navigate to System > Network > PBRs, on the PBR6s tab, in the Action list, select Renumber Priority (s).

MAC Address Wildcard Mask for PBRs

May 29, 2016

A wildcard mask parameter has been introduced for extended PBRs and PBR6s and is used with the source MAC address parameter to define a range of MAC addresses to be match against the source MAC address of outgoing packets.

Wild card masks specify which hexadecimal digits of the MAC address are used and which hexadecimal digits are ignored. The wildcard mask parameter specifies a series of ones and zeroes and has a length of 12 digits. Each digit is a mask for the corresponding hexadecimal digit of the MAC address. A zero digit in the wildcard mask indicates that the corresponding hexadecimal digit of the MAC address must be considered and a one digit indicates that the corresponding hexadecimal digit to be ignored.

The wildcard mask should meet the following conditions:

- Has only one series of zeroes
- Has only one series of ones
- Start with a series of zeroes

The following are some of the examples of valid wildcard masks:

- 000000111111
- 000000011111
- 000011111111

The following are some of the examples of invalid wildcard masks:

- 000000111100
- 111110000000
- 010101010101

For an PBR rule, a wildcard mask of 000000111111 for MAC address 96:fa:95:1d:67:4a defines the MAC address range 96:FA:95:00:00:00 - 96:FA:95:FF:FF:FF. This MAC address range is matched against the source MAC address of the outgoing packets.

To specify a range of source MAC addresses in a PBR rule by using the NetScaler command line

At the command prompt, type:

- **add ns pbr** <name> <action> -**srcMac** <mac_addr> -**srcMacMask** <string>
- **show ns pbr** <pbrname>

Example COPY

```
> add ns pbr PBR-1 ALLOW -srcip 192.0.2.34 -srcMac 96:fa:95:1d:67:4a –srcMacMask 000000111111 -nexthop 198.51.100.1

 Done
```

To specify a range of source MAC addresses in an PBR6 rule by using the NetScaler command line

At the command prompt, type:

- **add ns pbr6** <name> <action> -**srcMac** <mac_addr> -**srcMacMask** <string>
- **show pbr6** <pbr6name>

Example

COPY

```
> add ns pbr6 PBR6-1 ALLOW –srcipv6 2001:db8:0::7 -srcMac 96:fa:95:1d:67:4a –srcMacMask 000000001111 -nexthop 2001:db8:0::1

 Done
```

Using NULL Policy Based Routes to Drop Outgoing Packets

Jul 07, 2016

Some situations might demand that the NetScaler appliance drops specific outgoing packets instead of routing them, for example, in testing cases and during deployment migration.

NULL policy based routes can be used to drop specific outgoing packets. A NULL PBR is a type of PBR that has the nexthop parameter set to NULL. The NetScaler appliance drops outgoing packets that match a NULL PBR.

Configuring NULL PBRs for IPv4 Packets

To create a NULL PBR by using the NetScaler command line

At the command prompt, type:

- **add ns pbr** <name> ALLOW [**-td** <positive_integer>] [**-srcIP**

[<operator>] <srcIPVal>] [-srcPort [<operator>] <srcPortVal>] [**-destIP**

[<operator>] <destIPVal>] [-destPort [<operator>] <destPortVal>]

(**-nextHop NULL**)

[**-srcMac** <mac_addr> [-srcMacMask <string>]] [**-protocol**

<protocol> | **-protocolNumber** <positive_integer>] [**-vlan**

<positive_integer> | **-vxlan** <positive_integer>] [**-interface**

<interface_name>] [**-priority** <positive_integer>] [**-msr** (**ENABLED** |

DISABLED) [**-monitor** <string>]] [**-state** (**ENABLED** | **DISABLED**)]

[**-ownerGroup** <string>]

- apply ns pbrs
- show ns pbr <id>

To configure a NULL PBR by using the NetScaler GUI

Navigate to **System** > **Network** > **PBRs**, on the **PBRs** tab, add a **new NULL PBR**, or edit an existing NULL PBR.

Example

In the following sample configuration, NULL PBR6 PBR6-NULL-EXAMPLE-1 is configured for dropping any outgoing IPv6 packets from interface 1/5.

Example COPY

```
> add ns pbr PBR6-NULL-EXAMPLE-1 ALLOW –nextHop NULL -interface 1/5

 Done

> apply ns pbr6

 Done
```

Troubleshooting Routing Issues

May 11, 2012

To make your troubleshooting process as efficient as possible, begin by gathering information about your network. You need to obtain the following information about the NetScaler appliance and other systems in the Network:

- Complete Topology diagram, including interface connectivity and intermediate switch details.
- Running Configuration. You can use the show running command to get the running configuration for ns.conf and ZebOS.conf.
- Output of the History command, to determine whether any configuration changes were made when the issue arose.
- Output of the Top and ps -ax commands, to determine whether any routing daemon is over utilizing the CPU or is misbehaving.
- Any routing related core files in /var/core - nsm, bgpd, ospfd, or ripd. Check the time stamp to see if they are relevant.
- dr_error.log and dr_info.log files from /var/log.
- Output of the date command and time details for all relevant systems. Print dates across all devices one after another, so that the times on the log messages can be correlated with various events.
- Relevant ns.log, newnslog files.
- Configuration files, log files and command history details from upstream and downstream routers.

This document includes the following information:

- Generic Routing FAQs
- Troubleshooting OSPF-Specific Issues

Generic Routing FAQs

Mar 20, 2012

Users typically have the following questions about how to troubleshoot generic routing issues:

- How do I save the config files?

  The write command from VTYSH saves only ZebOS.conf. Run the save ns config command from NetScaler CLI to save both ns.conf and ZebOS.conf files.
- If I have configured both a static default route and a dynamically learned default route, which is the preferred default route?

  The dynamically learned route is the preferred default route. This behavior is unique to default routes. However, in case of the Network Services Module (NSM), unless the administrative distances are modified, a statically configured route in the RIB is preferred over a dynamic route. The route that is downloaded to the NSM FIB is the static route.
- How do I block the advertisement of default routes?

  After release 7.0, the default route is not injected into ZebOS.

  However, if you are working with 7.0 or an earlier release, you must apply a suitable route map with the

  However, if you are working with 7.0 or an earlier release, you must apply a suitable route map with the redistribute kernel command for each protocol to block default route advertisement. For example:

```
ns(config)#access-list 1 deny 0.0.0.0
ns(config)#access-list 2 permit any
ns(config)#route-map redist-kernel permit 5
ns(config-route-map)#match ip address 1
ns(config)#route-map redist-kernel permit 10
ns(config-route-map)#match ip address 2
ns(config-route-map)#q
ns(config)#router ospf 1
ns(config-router)#redistribute kernel route-map redist-kernel
ns(config-router)#q
ns(config)#q
ns#show route-map
route-map redist-kernel, permit, sequence 5
  Match clauses:
    ip address 1
  Set clauses:
route-map redist-kernel, permit, sequence 10
  Match clauses:
    ip address 2
  Set clauses:
ns#show access-list
Standard IP access list 1
```

```
    deny 0.0.0.0
Standard IP access list 2
    permit any
ns#
```

- How do I view the debug output of networking daemons?

  You can write debugging output from networking daemons to a file by entering the following log file command from the global configuration view in VTYSH:

  ```
  ns(config)#log file /var/ZebOS.log
  ```

  With release 8.1, you can direct debug output to the console by entering the terminal monitor command from VTYSH user view:

  ```
  ns#terminal monitor
  ```

- How do I collect cores of running daemons?

  You can use the gcore utility to collect cores of running daemons for processing by gdb. This might be helpful in debugging misbehaving daemons without bringing the whole routing operation to a standstill.

  ```
  gcore [-s] [-c core] [executable] pid
  ```

  The -s option temporarily stops the daemon while gathering the core image. This is a recommended option, because it guarantees that the resulting image shows the core in a consistent state.

  ```
  root@ns#gcore -s -c nsm.core /netscaler/nsm 342
  ```

- How do I run a batch of ZebOS commands?

  You can run a batch of ZebOS commands from a file by entering the VTYSH -f <file-name> command. This does not replace the running configuration, but appends to it. However, by including commands to delete the existing configuration in the batch file and then add those for the new, desired configuration, you can use this mechanism to replace a specific configuration:

  ```
  !
  router bgp 234
  network 1.1.1.1 255.255.255.0
  !
  route-map bgp-out2 permit 10
   set metric 9900
   set community 8602:300
  !
  ```

Troubleshooting OSPF-Specific Issues

Mar 20, 2012

Before you start debugging any OSPF specific issue, you must collect information from the NetScaler appliance and all systems in the affected LAN, including upstream and downstream routers. To begin, enter the following commands:

1. show interface from both nscli and VTYSH
2. show ip ospf interface
3. show ip ospf neighbor detail
4. show ip route
5. show ip ospf route
6. show ip ospf database summary
    1. If there are only few LSAs in the database, then enter show ip ospf database router, show ip ospf database A. network, show ip ospf database external, and other commands to get the full details of LSAs.
    2. If there are a large number of LSAs in the database, enter the show ip ospf database self-originated command.
7. show ip ospf
8. show ns ip. This ensures that the details of all VIPs of interest are included.
9. Get the logs from peering devices and run the following command:

    gcore -s -c xyz.core /netscaler/ospfd <pid>

Note: The gcore command is non-disruptive.

Collect additional information from the NetScaler as follows:

1. Enable logging of error messages by entering the following command from the global configuration view in VTYSH:

    ns(config)#log file /var/ospf.log

2. Enable debugging ospf events and log them by using the following command:

    ns(config)#log file /var/ospf.log

    Enable debug ospf lsa packet only if the number of LSAs in the database is relatively small (< 500).

Internet Protocol version 6 (IPv6)

Mar 20, 2012

A NetScaler appliance supports both server-side and client-side IPv6 and can therefore function as an IPv6 node. It can accept connections from IPv6 nodes (both hosts and routers) and from IPv4 nodes, and can perform Protocol Translation (RFC 2765) before sending traffic to the services. You have to license the IPv6 feature before you can implement it.

The following table lists some of the IPv6 features that the NetScaler appliance supports.

Table 1. Some Supported IPv6 Features

IPv6 features
IPv6 addresses for SNIPs (NSIP6, VIP6, and SNIP6)
Neighbor Discovery (Address Resolution, Duplicated Address Detection, Neighbor Unreachability Detection, Router Discovery)
Management Applications (ping6, telnet6, ssh6)
Static Routing and Dynamic routing (OSPF, BGP, RIPng, and ISIS)
Port Based VLANs
Access Control Lists for IPv6 addresses (ACL6)
IPv6 Protocols (TCP6, UDP6, ICMP6)
Server Side Support (IPv6 addresses for vservers, services)
USIP (Use source IP) and DSR (Direct Server Return) for IPv6
SNMP and CVPN for IPv6
HA with native IPv6 node address
IPv6 addresses for MIPs
Path-MTU discovery for IPv6

The following table lists NetScaler components that support IPv6 addresses and provides references to the topics that document the components.

Table 2. NetScaler Components That Support IPv6 Addresses and the Corresponding Documentation

NetScaler component	Topic that documents IPv6 support
Network	Adding, Customizing, Removing, Removing all, and Viewing routes.
SSL Offload	Creating IPv6 vservers for SSL Offload
SSL Offload	Specifying IPv6 SSL Offload Monitors
SSL Offload	Creating IPv6 SSL Offload Servers
Load Balancing	Creating IPv6 vservers for Load Balancing
Load Balancing	Specifying IPv6 Load Balancing Monitors
Load Balancing	Creating IPv6 Load Balancing Servers

NetScaler component	Topic that documents IPv6 support
DNS	Creating AAAA Records

You can configure IPv6 support for the above features after implementing the IPv6 feature on your NetScaler appliance. You can configure both tagged and prefix-based VLANs for IPv6. You can also map IPv4 addresses to IPv6 addresses.

Implementing IPv6 Support

IPv6 support is a licensed feature, which you have to enable before you can use or configure it. If IPv6 is disabled, the NetScaler does not process IPv6 packets. It displays the following warning when you run an unsupported command:

"Warning: Feature(s) not enabled [IPv6PT]"

The following message appears if you attempt to run IPv6 commands without the appropriate license:

"ERROR: Feature(s) not licensed"

After licensing the feature, use either of the following procedures to enable or disable IPv6.

To enable or disable IPv6 by using the command line interface

At the command prompt, type one of the following commands:

- enable ns feature ipv6pt
- disable ns feature ipv6pt

To enable or disable IPv6 by using the configuration utility

1. Navigate to System > Settings, in the Modes and Features group, click Configure Advanced Features.
2. Select or clear the IPv6 Protocol Translation option.

VLAN Support

Updated: 2013-08-30

If you need to send broadcast or multicast packets without identifying the VLAN (for example, during DAD for NSIP, or ND6 for the next hop of the route), you can configure the NetScaler appliance to send the packet on all the interfaces with appropriate tagging. The VLAN is identified by ND6, and a data packet is sent only on the VLAN.

For more information about ND6 and VLANs, see "Configuring Neighbor Discovery."

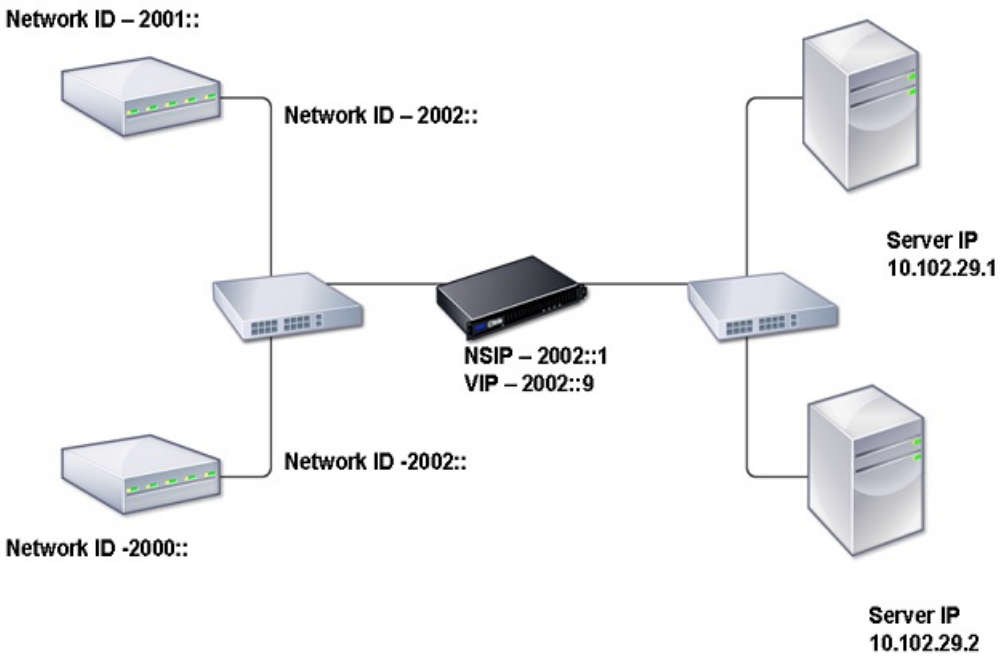
Port-based VLANs are common for IPv4 and IPv6. Prefix-based VLANs are supported for IPv6.

Simple Deployment Scenario

Updated: 2013-08-30

Following is an example of a simple load balancing set-up consisting of an IPv6 vserver and IPv4 services, as illustrated in the following topology diagram.

Figure 1. IPv6 Sample Topology

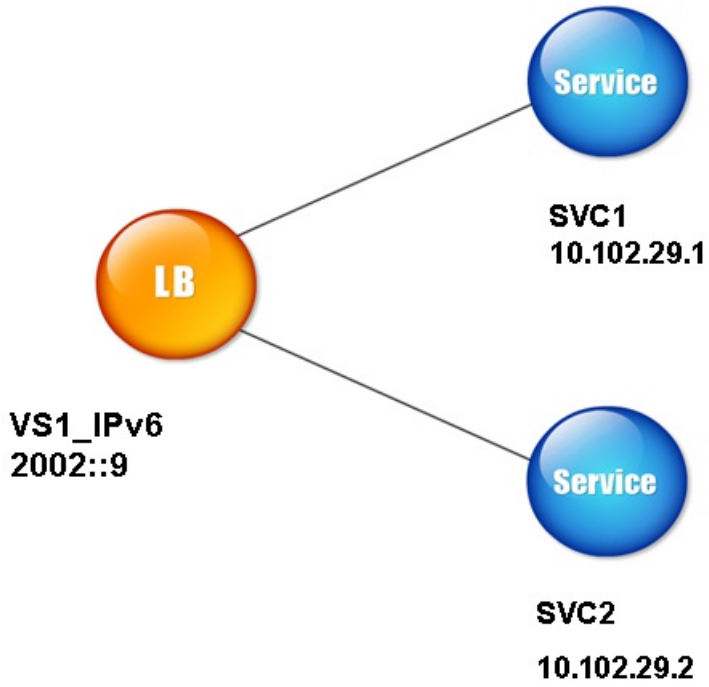


The following table summarizes the names and values of the entities that must be configured on the NetScaler.

Table 3. Sample Values for Creating Entities

Entity type	Name	Value
LB Vserver	VS1_IPv6	2002::9
Services	SVC1	10.102.29.1
	SVC2	10.102.29.2

The following figure shows the entities and values of the parameters to be configured on the NetScaler.
Figure 2. IPv6 Entity Diagram



To configure this deployment scenario, you need to do the following:

1. Create an IPv6 service.
2. Create an IPv6 LB vserver.
3. Bind the services to the vserver.

To create IPv4 services by using the command line interface

At the command prompt, type:

add service <Name> <IPAddress> <Protocol> <Port>

Example

add service SVC1 10.102.29.1 HTTP 80
add service SVC2 10.102.29.2 HTTP 80

To create IPv4 services by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, click Add, and then set the following parameters:

- Service Name
- IP Address
- Protocol
- Port

To create IPv6 vserver by using the command line interface

At the command prompt, type:

add lb vserver <Name> <IPAddress> <Protocol> <Port>

Example

add lb vserver VS1_IPv6 2002::9 HTTP 80

To create IPv6 vserver by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, click Add, and select the IPv6 check box.
2. Set the following parameters:
   - Name
   - Protocol
   - IP Address Type
   - IP Address
   - Port

To bind a service to an LB vserver by using the command line interface

At the command prompt, type:

bind lb vserver <name> <service>
Example

bind lb vserver VS1_IPv6 SVC1
The vservers receive IPv6 packets and the NetScaler performs Protocol Translation (RFC 2765) before sending traffic to the IPv4-based services.

To bind a service to an LB vserver by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the Load Balancing Virtual Servers page, select the vserver for which you want to bind the service (for example, VS1_IPv6).
3. Click Open.
4. In the Configure Virtual Server (Load Balancing) dialog box, on the Services tab, select the Active check box corresponding to the service that you want to bind to the vserver (for example, SVC1).
5. Click OK.
6. Repeat Steps 1-4 to bind the service (for example, SVC2 to the vserver).

Host Header Modification

Updated: 2013-08-30

When an HTTP request has an IPv6 address in the host header, and the server does not understand the IPv6 address, you must map the IPv6 address to an IPv4 address. The IPv4 address is then used in the host header of the HTTP request sent to the vserver.

To change the IPv6 address in the host header to an IPv4 address by using the command line interface

At the command prompt, type:

set ns ip6 <IPv6Address> -map <IPAddress>
Example

set ns ip6 2002::9 -map 200.200.200.200

To change the IPv6 address in the host header to an IPv4 address by using the configuration utility

1. Navigate to System > Network > IPs and, on the IPV6s tab, select the IP address for which you want to configure a mapped IP address, for example, 2002:0:0:0:0:0:0:9, and click Edit.
2. In the Mapped IP text box, type the mapped IP address that you want to configure, for example, 200.200.200.200.

VIP Insertion

Updated: 2013-08-30

If an IPv6 address is sent to an IPv4-based server, the server may not understand the IP address in the HTTP header, and may generate an error. To avoid this, you can map an IPv4 address to the IPv6 VIP and enable VIP insertion.

To configure a mapped IPv6 address by using the command line interface

At the command prompt, type:

set ns ip6 <IPv6Address> -map <IPAddress>
Example

```
> set ns ip6 2002::9 -map 200.200.200.200
 Done
```

To configure a mapped IPv6 address by using the configuration utility

1. Navigate to System > Network > IPs, on the IPV6s tab, select the IP address for which you want to configure a mapped IP address, for example, 2002:0:0:0:0:0:0:9, and click Edit.
2. In the Mapped IP text box, type the mapped IP address that you want to configure, for example, 200.200.200.200.

Use either of the following procedures to enable insertion of an Ipv4 VIP address and port number in the HTTP requests sent to the servers.

To enable VIP insertion by using the command line interface

At the command prompt, type:

set lb vserver <name> -insertVserverIPPort <Value>
Example

```
> set lb vserver VS1_IPv6 -insertVserverIPPort ON
 Done
```

To enable VIP insertion by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, select the vserver that you want to enable port insertion, and click Edit.
2. In the Advanced tab, under Traffic Settings, in the Vserver IP Port Insertion drop-down list box, select VIPADDR.
3. In the Vserver IP Port Insertion text box, type the vip header.

Traffic Domains

Feb 13, 2017

> **Important**
>
> Citrix recommends you to use Admin Partitions instead of using Traffic Domains. For more information, see Admin Partitioning page.

Traffic domains are a way to segment network traffic for different applications. You can use traffic domains to create multiple isolated environments within a NetScaler appliance. An application belonging to a specific traffic domain communicates with entities and processes traffic within that domain. The traffic belonging to one traffic domain cannot cross the boundary of another traffic domain.

Benefits of using Traffic Domains

The main benefits of using traffic domains on a NetScaler appliance are the following:

- **Use of duplicate IP addresses in a Network**. Traffic domains allow you to use duplicate IP address on the network. You can assign the same IP address or network address to multiple devices on a network, or multiple entities on a NetScaler appliance, as long as each of the duplicate address belongs to a different traffic domain.
- **Use of Duplicate entities on the NetScaler appliance**. Traffic domains also allow you to use duplicate NetScaler feature entities on the appliance. You can create entities with the same settings as long as each entity is assigned to a separate traffic domain.
  Note: Duplicate entities with same name is not supported.
- **Multitenancy**. Using traffic domains, you can provide hosting services for multiple customers by isolating each customer's type of application traffic within a defined address space on the network.

A traffic domain is uniquely identified by an identifier, which is an integer value. Each traffic domain needs a VLAN or a set of VLANs. The isolation functionality of the traffic domain depends on the VLANs bound to the traffic domain. More than one VLAN can be bound to a traffic domain, but the same VLAN cannot be a part of multiple traffic domains. Therefore, the maximum number of traffic domains that can be created depends on the number of VLANS configured on the appliance.

Default Traffic Domain

A NetScaler appliance has a preconfigured traffic domain, called the *default traffic domain*, which has an ID of 0. All factory settings and configurations are part of the default traffic domain. You can create other traffic domains and then segment traffic between the default traffic domain and each of the other traffic domains. You cannot remove the default traffic domain from the NetScaler appliance. Any feature entity that you create without setting the traffic domain ID is automatically associated with the default traffic domain.
Note: Some features and configurations are supported only in the default traffic domain. They do not work in nondefault traffic domains. For a list of the features supported in all traffic domains, see Supported NetScaler Features in Traffic Domains.

This section includes the following details:

- How Traffic Domains Work
- Supported NetScaler Features in Traffic Domains

- Configuring Traffic Domains

How Traffic Domains Work

As an illustration of traffic domains, consider an example in which two traffic domains, with IDs 1 and 2, are configured on NetScaler appliance NS1.

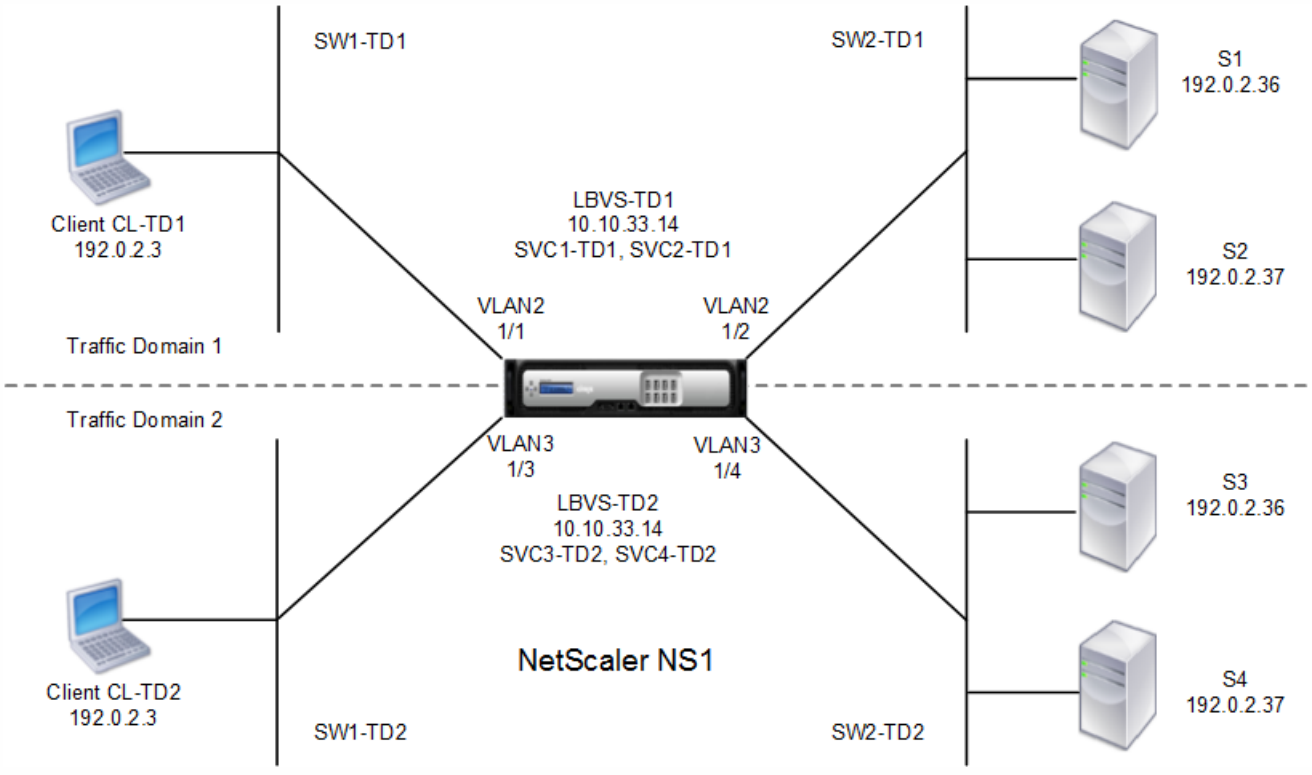
In traffic domain 1, load balancing virtual server LBVS-TD1 is configured to load balance traffic across servers S1 and S2. On the NetScaler appliance, servers S1 and S2 are represented by services SVC1-TD1 and SVC2-TD1, respectively. Servers S1 and S2 are connected to NS1 through L2 switch SW2-TD1. Client CL-TD1 is on a private network connected to NS1 through L2 switch SW1-TD1. SW1-TD1 and SW2-TD1 are connected to VLAN 2 of NS1. VLAN 2 is bound to traffic domain 1, which means that client CL-TD1 and servers S1 and S2 are part of traffic domain 1.

Similarly in traffic domain 2, load balancing virtual server LBVS-TD2 is configured to load balance traffic across S3 and S4. On the NetScaler appliance, servers S3 and S4 are represented by services SVC3-TD2 and SVC4-TD2, respectively. Servers S3 and S4 are connected to NS1 through L2 switch SW2-TD2. Client CL-TD2 is on a private network connected to NS1 through L2 switch SW1-TD2. SW1-TD2 and SW2-TD2 are connected to VLAN 3 of NS1. VLAN 3 is bound to traffic domain 2, which means that client CL-TD2 and servers S3 and S4 are part of traffic domain 2.

On the NetScaler appliance, entities LBVS-TD1 and LBVS-TD2 share the same settings, including the IP address. The same is true for SVC1-TD1 and SVC3-TD2, and for SVC2-TD1 and SVC4-TD2. This is possible because these entities are in different traffic domains.

Similarly, servers S1 and S3, S2 and S4 share the same IP address, and clients CL-TD1 and CL-TD2 each have the same IP address.

Figure 1. How traffic domains work



The following table lists the settings used in the example.

Entity	Name	Details
Settings in traffic domain 1		
VLANs bound to traffic domain 1	VLAN 2	VLAN Id: 2 Interfaces bound: 1/1, 1/2
Client connected to TD1	CL-TD1 (for reference purposes only)	IP address: 192.0.2.3
Load balancing virtual server in TD1	LBVS-TD1	IP address: 192.0.2.15
Service bound to virtual server LBVS-TD1	SVC1-TD1	IP address: 192.0.2.36
	SVC2-TD1	IP address: 192.0.2.37
SNIP	SNIP-TD1 (for reference purposes only)	IP address: 192.0.2.27
Settings in traffic domain 2		
VLAN bound to traffic domain 2	VLAN 3	VLAN Id: 3 Interfaces bound: 1/3, 1/4
Client connected to TD2	CL-TD2 (for reference purposes only)	IP address: 192.0.2.3
Load balancing virtual server in TD2	LBVS-TD2	IP address: 192.0.2.15
Service bound to virtual server LBVS-TD2	SVC3-TD2	IP address: 192.0.2.36
	SVC4-TD2	IP address: 192.0.2.37
SNIP in TD2	SNIP-TD2 (for reference purposes only)	IP address: 192.0.2.29

Following is the traffic flow in traffic domain 1:

1. Client CL-TD1 broadcasts an ARP request for the IP address of 192.0.2.15.
2. The ARP request reaches NS1 on interface 1/1, which is bound to VLAN 2. Because VLAN 2 is bound to traffic domain 1, NS1 updates the ARP table of traffic domain 1 for the IP address of client CL-TD1.
3. Because the ARP request is received on traffic domain 1, NS1 looks for an entity configured on traffic domain 1 that has an IP address of 192.0.2.15. NS1 finds that a load balancing virtual server LBVS-TD1 is configured on traffic domain 1 and has the IP address 192.0.2.15.
4. NS1 sends an ARP response with the MAC address of interface 1/1.
5. The ARP reply reaches CL-TD1. CL-TD1 updates its ARP table for the IP address of LBVS-TD1 with the MAC address of interface 1/1 of NS1.
6. Client CL-TD1 sends a request to 192.0.2.15. The request is received by LBVS-TD1 on port 1/1 of NS1.
7. LBVS-TD1's load balancing algorithm selects server S2, and NS1 opens a connection between a SNIP in traffic domain 1 (192.0.2.27) and S2.

8. S2 replies to SNIP 192.0.2.27 on NS1.
9. NS1 sends S2's reply to client CL-TD1.

Following is the traffic flow in traffic domain 2:

1. Client CL-TD2 broadcasts an ARP request for the IP address of 192.0.2.15.
2. The ARP request reaches NS1 on interface 1/3, which is bound to VLAN 3. Because VLAN 3 is bound to traffic domain 2, NS1 updates traffic-domain 2's ARP-table entry for the IP address of client CL-TD2, even though an ARP entry for the same IP address (CL-TD1) is already present in the ARP table of traffic domain 1.
3. Because the ARP request is received in traffic domain 2, NS1 searches traffic domain 2 for an entity that has an IP address of 192.0.2.15. NS1 finds that load balancing virtual server LBVS-TD2 is configured in traffic domain 2 and has the IP address 192.0.2.15. NS1 ignores LBVS-TD1 in traffic domain 1, even though it has the same IP address as LBVS-TD2.
4. NS1 sends an ARP response with the MAC address of interface 1/3.
5. The ARP reply reaches CL-TD2. CL-TD2 updates its ARP table entry for the IP address of LBVS-TD2 with the MAC address of interface 1/3 of NS1.
6. Client CL-TD2 sends a request to 192.0.2.15. The request is received by LBVS-TD2 on interface 1/3 of NS1.
7. LBVS-TD2's load balancing algorithm selects server S3, and NS1 opens a connection between a SNIP in traffic domain 2 (192.0.2.29) and S3.
8. S2 replies to SNIP 192.0.2.29 on NS1.
9. NS1 sends S2's reply to client CL-TD2.

Supported NetScaler Features in Traffic Domains

The NetScaler features in the following list are supported in all traffic domains.

> **Important**
>
> Any NetScaler feature not listed below is supported only in the default traffic domain.

- ARP table
- ND6 table
- Bridge table
- All types of IPv4 and IPv6 addresses
- IPv4 and IPv6 routes
- ACL and ACL6
- PBR & PBR6
- INAT
- RNAT
- RNAT6
- MSR
- MSR6
- Net profiles
- SNMP MIBs
- Fragmentation

- Content Switching
- Cache Redirection
- Persistency
- Service (Domain based services are not supported)
- Servicegroup (Domain based service groups are not supported)
- Policies (*)
- PING
- TRACEROUTE
- PMTU
- High Availability (connection mirroring is not supported)
- Cluster (Supported on L2 clusters. Not supported on L3 clusters)
- Cookie Persistency
- MSS
- Logging
- Priority Queuing
- Surge Protection
- HTTP DOSP (**)
- Load balancing (The following types are not supported:
  - TFTP
  - RTSP
  - Diameter
  - SIP
  - SMPP)
- NAT46
- NAT64
- DNS64

	• Forwarding Session Rules • SNMP

* Policies do not have global binding points for traffic domains. However, policies can be bound to a specific load balancing virtual server of a traffic domain.

** HTTP DOSP policies do not have global binding points for traffic domains. However, HTTP DOSP policies can be bound to a specific load balancing service of a traffic domain.

> **Note**
>
> Global Server Loading Balancing (GSLB) and ADNS features in NetScaler are not aware of Traffic Domains. If the GSLB configuration needs to be shared across all traffic domains then GSLB methods Static Proximity and Round Trip Time (RTT) do not work. As a workaround in this scenario you can use GSLB methods other than RTT and Static Proximity. For more information, see http://support.citrix.com/article/CTX202277.

Configuring Traffic Domains

Configuring a traffic domain on the NetScaler appliance consists of the following tasks:

- **Add VLANs.** Create VLANs and bind specified interfaces to them.
- **Create a traffic domain entity and bind VLANs to it.** This involves the following two tasks:
  - Create a traffic domain entity uniquely identified by an ID, which is an integer value.
  - Bind the specified VLANs to the traffic domain entity. All the interfaces that are bound to the specified VLANs are associated with the traffic domain. More than one VLAN can be bound to a traffic domain, but a VLAN cannot be a part of multiple traffic domains.
- **Create feature entities on the traffic domain**. Create the required feature entities in the traffic domain. The CLI commands and configuration dialog boxes of all the supported features in a nondefault traffic domain include a parameter called a *traffic domain identifier* (td). When configuring a feature entity, if you want the entity to be associated with a particular traffic domain, you must specify the td. Any feature entity that you create without setting the td is automatically associated with the default traffic domain.

To give you an idea of how feature entities are associated with a traffic domain, this topic covers the procedures for configuring all the entities mentioned in the section titled How Traffic Domains Work.

To create a VLAN and bind interfaces to it by using the command line interface

At the command prompt, type:
- add vlan <id>
- bind vlan <id> -ifnum <slot/port>
- show vlan <id>

To create a traffic domain entity and bind VLANs to it by using the command line interface

At the command prompt, type:
- add ns trafficdomain <td>
- bind ns trafficdomain <td> -vlan <id>
- show ns trafficdomain <td>

To create a service by using the command line interface

At the command prompt, type:

- add service <name> <IP> <serviceType> <port> -td <id>
- show service <name>

To create a load balancing virtual server and bind services to it by using the command line interface

At the command prompt, type:

- add lb vserver <name> <serviceType> <IPAddress> <port> -td <id>
- bind lb vserver <name> <serviceName>
- show lb vserver <name>

To create a VLAN by using the configuration utility

Navigate to System > Network > VLANs, click Add, and set the parameters.

To create a traffic domain entity by using the configuration utility

Navigate to System > Network > Traffic Domains, click Add, and in the Create Traffic Domain dialog box, set the parameters.

To create a service by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, click Add, and set the parameters.

To create a load balancing virtual server by using the configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Servers, click Add, and set the parameters.

Inter Traffic Domain Entity Bindings

Jun 17, 2014

You can bind services in one traffic domain to a virtual server in another traffic domain. All the services to be bound to a virtual server in a different traffic domain must reside in the same traffic domain.

You configure this support by using the existing bind lb vserver command or the related configuration utility procedure.

This capability can facilitate interaction between different traffic domains. In an enterprise, servers can be grouped in different traffic domains. Virtual servers are created in a traffic domain that faces the internet. A virtual server from this traffic domain can be configured to load balance servers in another traffic domain. This virtual server receives connection requests from the Internet to be forwarded to the bound servers.

When a NetScaler ADC is used in a cloud infrastructure, each tenant can be assigned a separate traffic domain, and all the resources (including servers) for a tenant can be grouped together in the tenant's traffic domain. For each tenant, a virtual server is created for load balancing servers in its traffic domain. All of these virtual servers are grouped together in a single traffic domain that faces the Internet.

Consider an example of in which cloud service provider Example-Cloud-A has three traffic domains, with IDs 10, 20, and 30, configured on NetScaler appliance NS1.

Example-Org-A and Example-Org-B are tenants of Example-Cloud-A. Tenant A is assigned traffic domain 20, and tenant B is assigned domain 30. Servers S1 and S2 reside in traffic domain 20 and servers S3 and S4 reside in traffic domain 30.

Traffic domain 10 faces the internet. Virtual servers LBVS-1 and LBVS-2 are created in traffic domain 10. LBVS-1, in traffic domain 10, is configured to load balance servers S1 and S2, which are in traffic domain 20. LBVS-2, in traffic domain 10, is configured to load balance servers S3 and S4, which are in traffic domain 30.

Therefore, these virtual servers accept Internet connection requests for servers that are in a different traffic domain than that of the virtual servers.

VMAC Based Traffic Domains

Jan 31, 2011

You can associate a traffic domain with a VMAC address instead of with VLANs. The NetScaler ADC then sends the traffic domain's VMAC address in all responses to ARP queries for network entities in that domain. As a result, the ADC can segregate subsequent incoming traffic for different traffic domains on the basis of the destination MAC address, because the destination MAC address is the VMAC address of a traffic domain. After creating entities on a traffic domain, you can easily manage and monitor them by performing traffic domain level operations.

Following are points to consider before you configure VMAC based traffic domain:

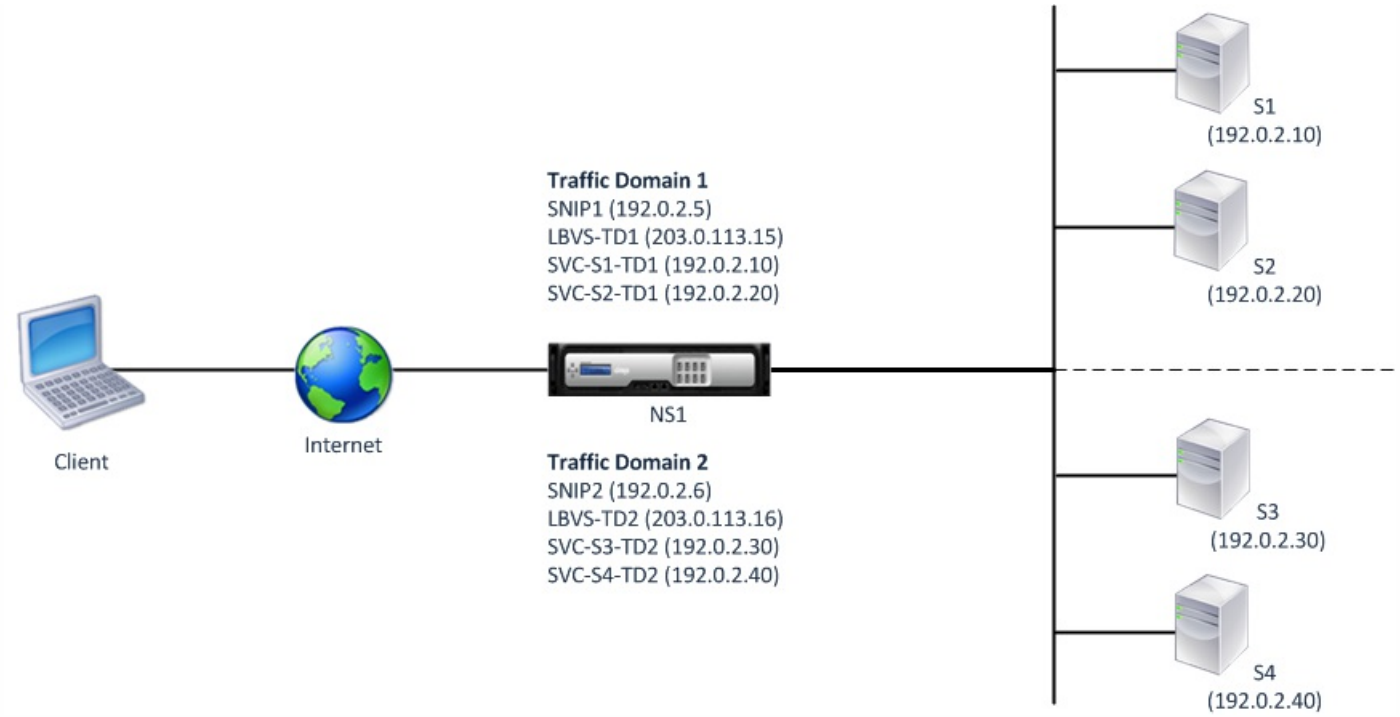
1. VMAC based traffic domains are easiest way to achieve network traffic segregation.
2. Because VMAC based traffic domains segregate network traffic based on VMAC addresses and not VLANS, you cannot create duplicate IP addresses on different VMAC based traffic domains on a NetScaler ADC.
3. VMAC based traffic domains do not work when the NetScaler is deployed only in L2 Mode.
4. Both VLAN and VMAC based traffic domains can coexist on a NetScaler ADC. VMAC based traffic domains actually runs on all VLANs that are not bound to any VLAN based traffic domain.

Consider an example in which two traffic domains, with IDs 1 and 2, are configured on NetScaler appliance NS1. The NetScaler creates a VMAC address VMAC1 and associates it with traffic domain 1. Similarly, the NetScaler created another VMAC address VMAC2 and associates with traffic domain 2.

In traffic domain 1, load balancing virtual server LBVS-TD1 is configured to load balance traffic across servers S1 and S2. On the NetScaler appliance, servers S1 and S2 are represented by services SVC1-TD1 and SVC2-TD1, respectively. A subnet IP address (SNIP) SNIP1 is configured for enabling the NetScaler to communicate with S1 and S2. Because VMAC1 is associated with traffic domain 1, the NetScaler sends VMAC1 as the MAC address in all ARP announcements and ARP responses for LBVS-TD1 and SNIP1.

Similarly in traffic domain 2, load balancing virtual server LBVS-TD2 is configured to load balance traffic across S3 and S4. On the NetScaler appliance, servers S3 and S4 are represented by services SVC3-TD2 and SVC4-TD2, respectively. A SNIP address SNIP2 is configured for enabling the NetScaler to communicate with S3 and S4. Because VMAC2 is associated with traffic domain 2, the NetScaler sends VMAC2 as the MAC address in all ARP announcements and ARP responses for LBVS-TD2 and SNIP2.

The NetScaler segregate subsequent incoming traffic for traffic domains 1 or 2 on the basis of the destination MAC address, if the destination MAC address is VMAC1 or VMAC2.



The following table lists the settings used in the example.

Entity	Name	Details
Settings in traffic domain 1		
VMAC Address	VMAC1 (for reference purposes only)	NS1 automatically creates VMAC1 and associates with traffic domain 1
SNIP address	SNIP1 (for reference purposes only)	192.0.2.5
Services on NS1 representing servers S1 and S2	SVC-S1-TD1	• IP address: 192.0.2.10 • Protocol: HTTP • Port: 80
	SVC-S2-TD1	• IP address: 192.0.2.20 • Protocol: HTTP • Port: 80
Load balancing virtual server	LBVS-TD1	• IP address: 203.0.113.15 • Protocol: HTTP • Port: 80 • Bound services: SVC-S1, SVC-S2
Settings in traffic domain 2		
VMAC Address	VMAC2 (for reference purposes only)	NS1 automatically creates VMAC2 and associates with traffic domain 2

Entity	Name	Details
SNIP address	SNIP2(for reference purposes only)	192.0.2.6
Services on NS1 representing servers S1 and S2	SVC-S3-TD2	• IP address: 192.0.2.30 • Protocol: HTTP • Port: 80
	SVC-S4-TD2	• IP address: 192.0.2.40 • Protocol: HTTP • Port: 80
Load balancing virtual server	LBVS-TD2	• IP address: 203.0.113.16 • Protocol: HTTP • Port: 80 • Bound services: SVC-S3, SVC-S4

Configuration Steps

Configuring a VMAC based traffic domain on a NetScaler appliance consists of the following tasks:

- Create a traffic domain entity and enable the VMAC option. Create a traffic domain entity uniquely identified by an ID, which is an integer value, and then enable the VMAC option. After creating the traffic domain entity, the NetScaler ADC creates a virtual MAC address and then associates it to the traffic domain entity.
- Create feature entities on the traffic domain. Create the required feature entities in the traffic domain by specifying the traffic domain identifier (td) when configuring these feature entities. NetScaler owned network entities created in a VMAC based traffic domain are associated with the VMAC address, which is associated with the traffic domain. The NetScaler ADC then sends the traffic domain's VMAC address in ARP announcements and ARP responses for these network entities.

To create a VMAC based traffic domain by using the command line interface

At the command prompt, type:

- add ns trafficDomain <td> [-vmac (ENABLED | DISABLED)]
- show ns trafficdomain <td>

To configure a SNIP address by using the command line interface

At the command prompt, type:

- add ns ip <IPAddress> <netmask> -type SNIP –td <id>
- show ns ip <IPAddress> -td <id>

To create a service by using the command line interface

At the command prompt, type:

- add service <name> <IP> <serviceType> <port> -td <id>
- show service <name> -td <id>

To create a load balancing virtual server and bind services to it by using the command line interface

At the command prompt, type:

- add lb vserver <name> <serviceType> <IPAddress> <port> -td <id>

- bind lb vserver <name> <serviceName>
- show lb vserver <name> -td <id>

Example

```
> add ns trafficDomain 1 -vmac ENABLED
 Done
> add ns trafficDomain 2 -vmac ENABLED
 Done

> add ns ip 192.0.2.5 255.255.255.0 -type -SNIP -td 1
 Done
> add service  SVC-S1-TD1  192.0.2.10 HTTP 80 -td 1
 Done
> add service  SVC-S2-TD1  192.0.2.20 HTTP 80 -td 1
 Done
> add lb vserver  LBVS-TD1 HTTP   203.0.113.15 80 -td 1
 Done
> bind lb vserver  LBVS-TD1 SVC-S1-TD1
 Done
> bind lb vserver  LBVS-TD1 SVC-S2-TD1
 Done

> add ns ip 192.0.2.6 255.255.255.0 -type -SNIP -td 2
 Done
> add service  SVC-S3-TD2  192.0.2.30 HTTP 80 -td 2
 Done
> add service  SVC-S4-TD2  192.0.2.40 HTTP 80 -td 2
 Done
> add lb vserver  LBVS-TD1 HTTP   203.0.113.16 80 -td 1
 Done
> bind lb vserver  LBVS-TD2 SVC-S3-TD2
 Done
> bind lb vserver  LBVS-TD2 SVC-S3-TD2
 Done
```

To create a VMAC based traffic domain by using the configuration utility

1. Navigate to System > Network > Interfaces.
2. In the details pane, click Add.
3. On the Create Traffic Domain page, set the following parameters:
   - Traffic Domain ID*
   - Enable Mac
4. Click Create.

To configure a SNIP address by using the configuration utility

1. Navigate to System > Network > IPs > IPv4
2. Navigate to Network > IPs > IPv4
3. In the details pane, click Add

4. In the Create IP page, set the following parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
   - IP Address
   - Netmask
   - IP Type
   - Traffic Domain ID
5. Click Create.

To create a service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, click Add.
3. In the Basic Settings Page, set the following parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
   - Service Name
   - Server
   - Protocol
   - Port
   - Traffic Domain ID
4. Click Continue, and click Done.
5. Repeat steps 2-4 to create another service.
6. Click Close.

To create a load balancing virtual server and bind services to it by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the Load Balancing Virtual Servers pane, click Add.
3. In the Create Virtual Servers (Load Balancing) dialog box, set the following parameters. For a description of a parameter, hover the mouse cursor over the corresponding field.
   - Name
   - IP Address
   - Protocol
   - Port
   - Traffic Domain ID
4. Click Continue, on the Service Pane, click >.
5. On the Service page, click Insert, and then select the check box for the services that you want to bind to the virtual server.
6. Click Continue, and click Done.
7. Repeat steps 2-5 to create another virtual server

VXLAN

Feb 13, 2017

NetScaler appliances support Virtual eXtensible Local Area Networks (VXLANs). A VXLAN overlays Layer 2 networks onto a layer 3 infrastructure by encapsulating Layer-2 frames in UDP packets. Each overlay network is known as a VXLAN Segment and is identified by a unique 24-bit identifier called the *VXLAN* Network Identifier (VNI). Only network devices within the same VXLAN can communicate with each other.

VXLANs provide the same Ethernet Layer 2 network services that VLANs do, but with greater extensibility and flexibility. The two main benefits of using VXLANs are the following:

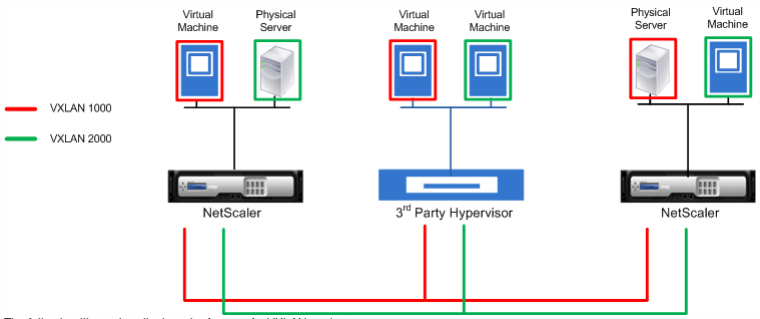
- **Higher scalability.** Server virtualization and cloud computing architectures have dramatically increased the demand for isolated Layer 2 networks in a datacenter. The VLAN specification uses a 12-bit VLAN ID to identify a Layer 2 network, so you cannot scale beyond 4094 VLANs. That number can be inadequate when the requirement is for thousands of isolated Layer 2 networks. The 24-bit VNI accommodates up to 16 million VXLAN segments in the same administrative domain.
- **Higher flexibility.** Because VXLAN carries Layer 2 data frames over Layer 3 packets, VXLANs extend L2 networks across different parts of a datacenter and across geographically separated datacenters. Applications that are hosted in different parts of a datacenter and in different datacenters but are part of the same VXLAN appear as one contiguous network.

This section includes the following details:

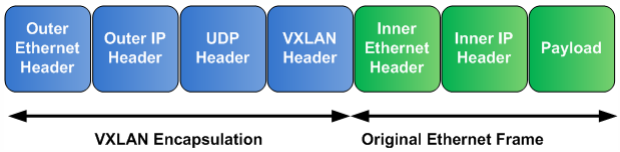
How VXLANs Work

VXLAN Segments are created between VXLAN Tunnel End Points (VTEPs). VTEPs support the VXLAN protocol and perform VXLAN encapsulation and decapsulation. You can think of a VXLAN segment as a tunnel between two VTEPs, where one VTEP encapsulates a Layer2 frame with a UDP header and an IP header and sends it through the tunnel. The other VTEP receives and decapsulates the packet to get the Layer 2 frame. A NetScaler ADC is one example of a VTEP. Other examples are third-party hypervisors, VXLAN aware virtual machines, and VXLAN capable switches.

The following illustration displays virtual machines and physical servers connected through VXLAN tunnels.



The following illustration displays the format of a VXLAN packet.



VXLANs on a NetScaler ADC use a Layer 2 mechanism for sending broadcast, multicast, and unknown unicast frames. A VXLAN supports the following modes for sending these L2 frames.

- Unicast mode: In this mode, you specify the IP addresses of VTEPs while configuring a VXLAN on a NetScaler ADC. The NetScaler ADC sends broadcast, multicast, and unknown unicast frames over Layer 3 to all VTEPs of this VXLAN.
- Multicast mode: In this mode, you specify a multicast group IP address while configuring a VXLAN on a NetScaler ADC. NetScaler ADCs do not support Internet Group Management Protocol (IGMP) protocol. NetScaler ADCs rely on the upstream router to join a multicast group, which shares a common multicast group IP address. The NetScaler ADC sends broadcast, multicast, and unknown unicast frames over Layer 3 to the multicast group IP address of this VXLAN.

Similar to a Layer 2 bridge table, NetScaler ADCs maintain VXLAN mapping tables based on the inner and outer header of the received VXLAN packets. This table maps of remote host MAC addresses to VTEP IP addresses for a particular VXLAN. The NetScaler ADC uses the VXLAN mapping table to look up the destination MAC address of a Layer 2 frame. If an entry for this MAC address is present in the VXLAN table, the NetScaler ADC sends the Layer 2 frame over Layer 3, using the VXLAN protocol, to the mapped VTEP IP address specified in the mapping entry for a VXLAN.

On a NetScaler ADC, you configure a VXLAN by creating a VXLAN tunnel and a VXLAN entity, and then bind the VXLAN tunnel to the VXLAN entity. A VXLAN tunnel is an IP tunnel with VXLAN as the underlying protocol. The VXLAN tunnel also specifies the local VTEP IP address and the remote VTEP IP address. The local VTEP IP address can be one of the configured subnet IP addresses on the NetScaler ADC. The remote IP address can be the IP address of a VTEP or the IP address of a multicast group. The VXLAN entity specifies the desired VXLAN Network Identifier (VNI).

Because VXLANs function similarly to VLANs, most of the NetScaler features that support VLAN as a classification parameter support VXLAN. These features include an optional VXLAN parameter setting, which specifies the VXLAN VNI.

In a high availability (HA) configuration, the VXLAN configuration is propagated or synchronized to the secondary node.

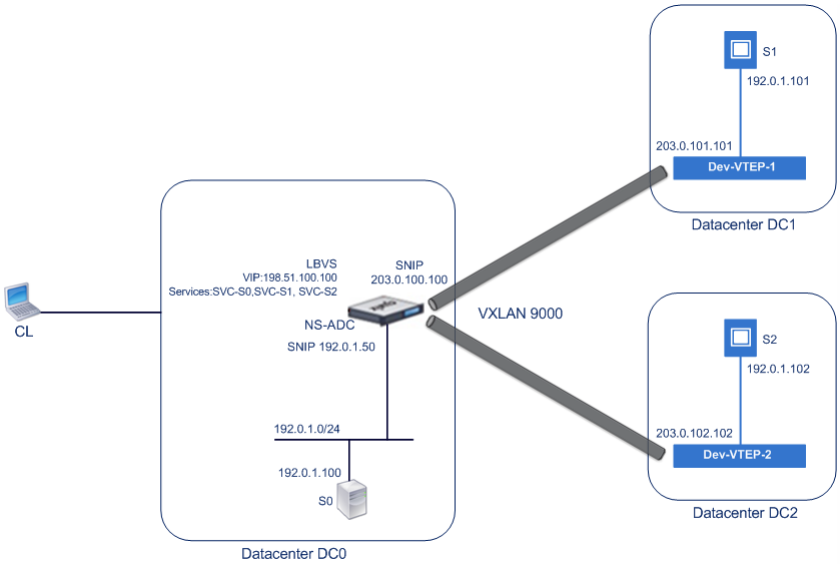
VXLAN Use Case: Load Balancing across Datacenters

To understand the VXLAN functionality of a NetScaler ADC, consider an example in which Example Corp hosts a site at www.example.com. To ensure application availability, the site is hosted on three servers, S0, S1, and S2. A load balancing virtual server, LBVS, on NetScaler ADC NS-ADC is used to load balance these servers. S0, S1, and S2 reside in datacenters DC0, DC1, and DC2, respectively. In DC0, server S0 is connected to NS-ADC.

S0 is a physical server, and S1 and S2 are virtual machines (VMs). S1 runs on virtualization host device Dev-VTEP-1 in datacenter DC1, and S2 runs on host device Dev-VTEP-2 in DC2. NS-ADC, Dev-VTEP-1, and Dev-VTEP-2 support the VXLAN protocol.

S0, S1, and S2 are part of the same private subnet, 192.0.1.0/24. For enabling NS-ADC, S0, S1, and S2 be part of a common broadcast domain, VXLAN 9000 is configured on NS-ADC, Dev-VTEP-1, and Dev-VTEP-2. Servers S1 and S2 are made part of VXLAN9000 on Dev-VTEP-1 and Dev-VTEP-2, respectively.

On NS-ADC, VXLAN 9000 configuration consists of a VXLAN entity, with an ID (VNI) of 9000, and two IP tunnels, VXLAN-9000-Tunnel-1 and VXLAN-9000-Tunnel-2. Both tunnels use VXLAN as the tunnel protocol. VXLAN-9000-Tunnel-1 is a VXLAN tunnel between a SNIP address (SNIP-VTEP-0) of NS-ADC and the IP address of Dev-VTEP-1. VXLAN-9000-Tunnel-2 is a VXLAN tunnel between a SNIP address (SNIP-VTEP-0) of NS-ADC and the IP address of Dev-VTEP-2. Both VXLAN tunnels are bound to VXLAN 9000.



The following table lists the settings used in this example.

Entity	Name	Details
Settings on NetScaler ADC NS-ADC in Datacenter DC-0		
Subnet IP address used by NS-ADC for communicating with servers S0, S1, and S2	SNIP-for-Servers (for reference purposes only)	IP address: 192.0.1.50
Local VTEP IP address, of type SNIP, for VXLAN 9000	SNIP-VTEP-0 (for reference purposes only)	IP address: 203.0.100.100
IP Tunnels of type VXLAN	VXLAN-9000-Tunnel-1	• Remote IP: 203.0.101.101 • Local IP: 203.0.100.100 • Tunnel protocol: VXLAN
	VXLAN-9000-Tunnel-2	• Remote IP: 203.0.102.102 • Local IP: 203.0.100.100 • Tunnel protocol: VXLAN
VXLAN Entity	VXLAN-9000 (For reference purposes only)	• ID (VNI): 9000 • UDP Port: 4789 • Bound VXLAN tunnels: VXLAN-9000-Tunnel-1, • VXLAN-9000-Tunnel-2
Server S0		• IP address: 192.0.1.100
Services on NS-ADC representing servers S0, S1, and S2	SVC-S0	• IP address: 192.0.1.100 • Protocol: HTTP • Port: 80
	SVC-S1	• IP address: 192.0.1.101 • Protocol: HTTP • Port: 80
	SVC-S2	• IP address: 192.0.1.102 • Protocol: HTTP • Port: 80 • Bound services: SVC-S1, SVC-S2
Settings on datacenter DC-1		
VXLAN Settings on Dev-VTEP-2		• ID (VNI): 9000 • UDP Port : 4789 • Remote VTEP IP address: 203.0.100.100 • Local VTEP IP address: 203.0.101.101
Server S1		• IP address: 192.0.1.101
Settings on datacenter DC-2		
VXLAN Settings on Dev-VTEP-2		• ID (VNI): 9000 • UDP Port : 4789 • Remote VTEP IP address: 203.0.100.100 • Local VTEP IP address: 203.0.102.102
Server S2		• IP address: 192.0.1.102

Services SVC-S0, SVC-S1, and SVC-S2 on NS-ADC represent S0, S1, and S2. As soon as these services are configured, NS-ADC broadcasts ARP requests for S0, S1, and S2 to resolve IP-to-MAC mapping. These ARP requests are also sent over VXLAN 9000 to Dev-VTEP-1 and Dev-VTEP-2.

Following is the traffic flow for resolving the ARP request for S2:

1. NS-ADC broadcasts an ARP request for S2 to resolve IP-to-MAC mapping. This packet has:
   - Sourced IP address = Subnet IP address SNIP-for-Servers (192.0.1.50)
   - Source MAC address = MAC address of the NS-ADC's interface from which the packet is sent out = NS-MAC-1
2. NS-ADC prepares the ARP packet to be sent over the VXLAN 9000 by encapsulating the packet with following headers:
   - VXLAN header with an ID (VNI) of 9000
   - Standard UDP header, UDP checksum set to 0×0000, and destination port set to 4789.
3. NS-ADC sends the resulting encapsulated packet to Dev-VTEP-1 and Dev-VTEP-2 on tunnels VXLAN-9000-Tunnel-1 and VXLAN-9000-Tunnel-2, respectively. The encapsulated packet has:
   - Source IP address = SNIP-VTEP-0 (203.0.100.100).
4. Dev-VTEP-2 receives the UDP packet and decapsulates the UDP header, from which Dev-VTEP-2 learns that the packet is a VXLAN related packet. Dev-VTEP-2 then decapsulates the VXLAN header and learns the VXLAN ID of the packet. The resulting packet is the ARP request packet for S2, which is same as in step 1.
5. From the inner and outer header of the VXLAN packet, Dev-VTEP-2 makes an entry in its VXLAN mapping table that shows the mapping of MAC address (NS-MAC-1) and SNIP-VTEP-0 (203.0.100.100) for VXLAN9000.
6. Dev-VTEP-2 sends the ARP packet to S2. S2's response packet reaches Dev-VTEP-2. Dev-VTEP-2 performs a lookup in its VXLAN mapping table and gets a match for the destination MAC address NS-MAC-1. The Dev-VTEP-2 now knows that NS-MAC-1 is reachable through SNIP-VTEP-0 (203.0.100.100) over VXLAN 9000.
7. S2 responds with its MAC address (MAC-S2). The ARP response packet has:
   - Destination IP address = Subnet IP address SNIP-for-Servers (192.0.1.50)
   - Destination MAC address = NS-MAC-1
8. S2's response packet reaches Dev-VTEP-2. Dev-VTEP-2 performs a lookup in its VXLAN mapping table and gets a match for the destination MAC address NS-MAC-1. The Dev-VTEP-2 now knows that NS-MAC-1 is reachable through SNIP-VTEP-0 (203.0.100.100) over VXLAN 9000. Dev-VTEP-2 encapsulates the ARP response with VXLAN and UDP headers, and sends the resultant packet to SNIP-VTEP-0 (203.0.100.100) of NS-ADC.
9. NS-ADC on receiving the packet, decapsulates the packet by removing the VXLAN and UDP headers. The resultant packet is S2's ARP response. NS-ADC updates it VXLAN mapping table for S2's MAC address (MAC-S2) with Dev-VTEP-2's IP address (203.0.102.102) for VXLAN 9000. NS-ADC also updates it ARP table for S2's IP address (192.0.1.102) with S2's MAC address (MAC-S2).

Following is the traffic flow for load balancing virtual server LBVS in this example:

1. Client CL sends a request packet to LBVS of NS-ADC. The request packet has:
   - Source IP address = IP address of client CL (198.51.100.90)
   - Destination IP address = IP address (VIP) of LBVS = 198.51.110.100
2. LBVS of NS-ADC receives the request packet, and its load balancing algorithm selects server S2 of datacenter DC2.
3. NS-ADC processes the request packet, changing its destination IP address to the IP address of S2 and its source IP address to one of the Subnet IP (SNIP) addresses configured on NS-ADC. The request packet has:
   - Source IP address = Subnet IP address on NS-ADC= SNIP-for-Servers (192.0.1.50)
   - Destination IP address = IP address of S2 (192.0.1.102)
4. NS-ADC finds a VXLAN mapping entry for S2 in its bridge table. This entry indicates that S2 is reachable through Dev-VTEP-2 over VXLAN 9000.
5. NS-ADC prepares the packet to be sent over the VXLAN 9000 by encapsulating the packet with following headers:
   - VXLAN header with an ID (VNI) of 9000
   - Standard UDP header, UDP checksum set to 0×0000, and destination port set to 4789.
6. NS-ADC sends the resulting encapsulated packet to Dev-VTEP-2. The request packet has:
   - Source IP address = SNIP address = SNIP-VTEP-0 (203.0.100.100)
   - Destination IP address = IP address of Dev-VTEP-2 (203.0.102.102)
7. Dev-VTEP-2 receives the UDP packet and decapsulates the UDP header, from which Dev-VTEP-2 learns that the packet is a VXLAN related packet. Dev-VTEP-2 then decapsulates the VXLAN header and learns the VXLAN ID of the packet. The resulting packet is the same packet as in step 3.
8. Dev-VTEP-2 then forwards the packet to S2.
9. S2 processes the request packet and sends the response to the SNIP address of NS-ADC. The response packet has:
   - Source IP address = IP address of S2 (192.0.1.102)
   - Destination IP address = Subnet IP address on NS-ADC= SNIP-for-Servers (192.0.1.50)
10. Dev-VTEP-2 encapsulates the response packet in the same way that NS-ADC encapsulated the request packet in steps 4 and 5. Dev-VTEP-2 then sends the encapsulated UDP packet to SNIP address SNIP-for-Servers (192.0.1.50) of NS-ADC.
11. NS-ADC, upon receiving the encapsulated UDP packet, decapsulates the packet by removing the UDP and VXLAN headers in the same way that Dev-VTEP-2 decapsulated the packet in step 7. The resultant packet is the same response packet as in step 9.
12. NS-ADC then uses the session table for load balancing virtual server LBVS, and forwards the response packet to client CL. The response packet has:
    - Source IP address = IP address of client CL (198.51.100.90)
    - Destination IP address = IP address (VIP) of LBVS (198.51.110.100)

Points to Consider for Configuring VXLANs

Consider the following points before configuring VXLANs on a NetScaler ADC:

- A maximum of 2048 VXLANs can be configured on a NetScaler ADC.
- VXLANs are not supported in a cluster.
- Link-local IPv6 addresses cannot be configured for each VXLAN.
- NetScaler ADCs do not support Internet Group Management Protocol (IGMP) protocol to form a multicast group. NetScaler ADCs rely on the IGMP protocol of its upstream router to join a multicast group, which share a common multicast group IP address. You can specify a multicast group IP address while creating a VXLAN tunnel but the multicast group must be configured on the upstream router. The NetScaler ADC sends broadcast, multicast, and unknown unicast frames over Layer 3 to the multicast group IP address of this VXLAN. The upstream router then forwards the packet to all the VTEPs that are part of the multicast group.
- VXLAN encapsulation adds an overhead of 50 bytes to each packet:
  Outer Ethernet Header (14) + UDP header (8) + IP header (20) + VXLAN header (8) = 50 bytes

  To avoid fragmentation and performance degradation, you must adjust the MTU settings of all network devices in a VXLAN pathway, including the VXLAN VTEP devices, to handle the 50 bytes of overhead in the VXLAN packets.

  Important: Jumbo frames are not supported on the NetScaler VPX virtual appliances, NetScaler SDX appliances, and NetScaler MPX 15000/17000 appliances. These appliances support an MTU size of only 1500 bytes and cannot be adjusted to handle the 50 bytes overhead of VXLAN packets. VXLAN traffic might be fragmented or suffer performance degradation, if one of these appliances is in the VXLAN pathway or acts as a VXLAN VTEP device.
- On NetScaler SDX appliances, VLAN filtering does not work for VXLAN packets.
- IPv6 Dynamic Routing is not supported on VXLAN.
- You cannot set a MTU value on a VXLAN.
- You cannot bind interfaces to a VXLAN.

Configuration Steps

Configuring a VXLAN on a NetScaler appliance consists of the following tasks.

- **Create an IP tunnel of type VXLAN**. Create an IP tunnel with VXLAN as the protocol for the IP tunnel. You specify one of the configured SNIP address for the local IP address of the tunnel. For the remote IP address you can specify either a multicast group IP address or a unicast address of a VTEP device. If you specify a multicast group IP address, you must configure IGMP on the upstream router of the NetScaler ADC to join the multicast group. Also, you can specify the configured VLAN through which the NetScaler ADC sends VXLAN packets to the multicast group IP address. In other words, the upstream router must be available on this VLAN. The upstream router forwards the VXLAN packets, from NS-ADC, to all the VTEPs that are part of the multicast group.
- **Create a VXLAN entity**. Create a VXLAN entity uniquely identified by a positive integer, which is also called the VXLAN Network Identifier (VNI). In this step, you can also specify the destination UDP port of remote VTEP on which the VXLAN protocol is running. By default, the destination UDP port parameter is set to 4789 for the VXLAN entity. This UDP port setting must match the settings on all remote VTEPs for this VXLAN. In this step, you can also bind VLANs to this VXLAN. The traffic (which includes broadcasts, multicasts, unknown unicasts) of all bound VLANs are allowed over this VXLAN. If no VLANs are bound to the VXLAN, the NetScaler ADC allows traffic of all VLANs, on this VXLAN, that are not part of any other VXLANs.
- **Bind the VXLAN tunnel to the VXLAN entity**. Bind the desired IP tunnels, of type VXLAN, to the VXLAN entity. More than one VXLAN tunnels can be bound to the VXLAN entity. These VXLAN

tunnels form the broadcast domain for the VXLAN identified by its VNI.

- **(Optional) Bind different feature entities to the configured VXLAN**. VXLANs function similarly to VLANs, most of the NetScaler ADC features that support VLAN as a classification parameter also support VXLAN. These features include an optional VXLAN parameter setting, which specifies the VXLAN VNI.
- **(Optional) Display the VXLAN mapping table**. Display the VXLAN mapping table, which includes mapping entries for remote host MAC address to VTEP IP address for a particular VXLAN. In other words, a VXLAN mapping states that a host is reachable through the VTEP on a particular VXLAN. The NetScaler ADC learns VXLAN mappings and updates its mapping table from the VXLAN packets it receives. The NetScaler ADC uses the VXLAN mapping table to lookup for the destination MAC address of a Layer 2 frame. If an entry for this MAC address is present in the VXLAN table, the NetScaler ADC sends the Layer 2 frame over Layer 3, using the VXLAN protocol, to the mapped VTEP IP address specified in the mapping entry for a VXLAN.

Configuration Using the Command Line Interface

To create a VXLAN tunnel by using the command line interface

At the command prompt, type:

- add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol VXLAN [-vlan <positive_integer>]
- show ipTunnel <name>

To create a VXLAN entity by using the command line interface

At the command prompt, type:

- add vxlan <id> [-vlan <positive_integer>] [-port <port>]
- show vxlan <id>

To bind a VXLAN tunnel to a VXLAN entity by using the command line interface

At the command prompt, type:

- bind vxlan <id> -tunnel <string>
- show vxlan <id>

To display the VXLAN forwarding table by using the command line interface

At the command prompt, type:

show bridgetable
Example

```
> add ipTunnel VXLAN-9000-Tunnel-1 203.0.101.101 255.255.255.255 203.0.100.100 -protocol VXLAN
 Done

> add ipTunnel VXLAN-9000-Tunnel-2 203.0.102.102 255.255.255.255 203.0.100.100 -protocol VXLAN
 Done

> add vxlan 9000
Done

> bind vxlan 9000 -tunnel VXLAN-9000-Tunnel-1
Done

> bind vxlan 9000 -tunnel VXLAN-9000-Tunnel-2
Done
```

Configuration Using the Configuration Utility

To create a VXLAN tunnel by using the configuration utility

Navigate to System > Network > IP Tunnels, and add a tunnel of type VXLAN.

To create a VXLAN entity and bind a VXLAN tunnel by using the configuration utility

1. Navigate to System > Network > VXLANs, and add a new VXLAN entity.
2. Open a VXLAN entity, in the VXLAN IP Tunnel Bindings pane, bind a VXLAN tunnel to the VXLAN entity.

To display the VXLAN forwarding table by using the configuration utility

Navigate to System > Network > Bridge Table.

Support of IPv6 Dynamic Routing Protocols on VXLANs

The NetScaler appliance supports IPv6 dynamic routing protocols for VXLANs. You can configure various IPv6 Dynamic Routing protocols (for example, OSPFv3, RIPng, BGP) on VXLANs from the VTYSH command line. An option IPv6 Dynamic Routing Protocol has been added to VXLAN command set for enabling or disabling IPv6 dynamic routing protocols on a VXLAN. After enabling IPv6 dynamic routing protocols on a VXLAN, processes related to the IPv6 dynamic routing protocols are required to be started on the VXLAN by using the VTYSH command line.
To enable IPv6 Dynamic routing protocols on a VXLAN by using the NetScaler command line

- add vxlan <ID> [-ipv6DynamicRouting (ENABLED | DISABLED)]
- show vxlan

Example

In the following sample configuration, VXLAN-9000 is created and has IPv6 dynamic routing protocols enabled on it. Then, using the VTYSH command line, process for the IPv6 OSPF protocol is start > add ipTunnel VXLAN-9000-Tunnel-1 203.0.101.101 255.255.255.255 203.0.100.100 -protocol VXLAN Done > add vxlan 9000 -ipv6DynamicRouting ENABLED Done > bind vxlan 9000 -tunnel VXLA

Extending VLANs from Multiple Enterprises to a Cloud using VXLAN-VLAN Maps

CloudBridge Connector tunnels is used to extend an enterprise's VLAN to a cloud. VLANs extended from multiple enterprises can have overlapping VLAN IDs. You can isolate each enterprise's VLANs, by mapping them to a unique VXLAN in the cloud. On a NetScaler appliance, which is the CloudBridge connector endpoint in the cloud, you can configure a VXLAN-VLAN map that links an enterprise's VLANs to a unique VXLAN in the cloud. VXLANs support VLAN tagging for extending multiple VLANs of an enterprise from CloudBridge Connector to the same VXLAN.

Perform the following tasks for extending VLANs of multiple enterprises to a cloud:

1. Create a VXLAN-VLAN map.
2. Bind the VXLAN-VLAN map to a network bridge based or PBR based CloudBridge Connector tunnel configuration on the NetScaler appliance on cloud.
3. (Optional) Enable VLAN tagging in a VXLAN configuration.

To add a VXLAN-VLAN map by using the NetScaler command line

- **add vxlanVlanMap** <name>
- **show vxlanVlanMap** <name>

To bind a VXLAN and VLANS to a VXLAN-VLAN map by using the NetScaler command line

- **bind vxlanVlanMap** <name> [-**vxlan** <positive_integer> -**vlan** <int[-int]> ...]
- **show vxlanVlanMap** <name>

To bind a VXLAN-VLAN map to a network bridge based CloudBridge Connector tunnel by using the NetScaler command line

At the command prompt, type one of the following sets of commands.

if adding a new network bridge:

- **add netbridge** <name> [-**vxlanVlanMap** <string>]
- **show netbridge** <name>

if reconfiguring an existing network bridge:

- **set netbridge** <name> [-**vxlanVlanMap** <string>]
- **show netbridge** <name>

To bind a VXLAN-VLAN map to a PBR based CloudBridge Connector tunnel by using the NetScaler command line

At the command prompt, type one of the following sets of commands.

if adding a new PBR:

- **add pbr** <name> **ALLOW** (-**ipTunnel** <ipTunnelName> [-**vxlanVlanMap** <name>])
- **show pbr** <name>

if reconfiguring an existing PBR:

- **set pbr** <name> **ALLOW** (-**ipTunnel** <ipTunnelName> [-**vxlanVlanMap** <name>])
- **show pbr** <name>

To include VLAN tags in packets related to a VXLAN by using the NetScaler command line

At the command prompt, type one of the following sets of commands.

if adding a new VXLAN:

- **add vxlan** <vnid> -**vlanTag** (**ENABLED** | **DISABLED**)
- **show vxlan** <vnid>

if reconfiguring an existing VXLAN:

- **set vxlan** <vnid> -**vlanTag** (**ENABLED** | **DISABLED**)
- **show vxlan** <vnid>

To add a VXLAN-VLAN map by using the NetScaler GUI

Navigate to **System** > **Network** > **VXLAN VLAN Map**, add a VXLAN VLAN map.

To bind a VXLAN-VLAN map to a netbridge based CloudBridge Connector tunnel by using the NetScaler GUI

Navigate to **System** > **CloudBridge Connector** > **Network Bridge**, select a VXLAN-VLAN map from the **VXLAN VLAN** drop down list while adding a new network bridge, or reconfiguring an existing network bridge.

To bind a VXLAN-VLAN map to a PBR based CloudBridge Connector tunnel by by using the NetScaler GUI

Navigate to **System** > **Network** > **PBRs**, on the Policy Based Routing (PBRs) tab, select a **VXLAN-VLAN** map from the **VXLAN VLAN** drop down list while adding a new PBR, or reconfiguring an existing PBR.

To include VLAN tags in packets related to a VXLAN by using the NetScaler GUI

Navigate to **System** > **Network** > **VXLANs**, enable **Inner VLAN Tagging** while adding a new VXLAN, or reconfiguring an existing VXLAN.

Sample Configuration COPY

```
> add vxlanVlanMap VXLANVLAN-DC1

Done

> bind vxlanvlanmap VXLANVLAN-DC1 -vxlan 3000 -vlan 3

Done

> bind vxlanvlanmap VXLANVLAN-DC1 -vxlan 3500 -vlan 4

Done

>add vxlanVlanMap VXLANVLAN-DC2

Done

> bind vxlanvlanmap VXLANVLAN-DC1 -vxlan 8000 -vlan 3 4

Done

> set pbr PBR-CBC-DC-1-CLOUD ALLOW  -ipTunnel  CBC-DC-1-CLOUD -vxlanVlanMap VXLANVLAN-DC1

Done

> set pbr PBR-CBC-DC-2-CLOUD ALLOW  -ipTunnel  CBC-DC-2-CLOUD -vxlanVlanMap VXLANVLAN-DC2

Done
```

Optimization

May 13, 2016

The NetScaler optimization features reduce transaction times between the clients and the servers, and they reduce bandwidth consumption. They also enhance server performance by offloading some tasks and making others more efficient.

Client Keep-Alive	Handles multiple requests on a single client connection. The client does not have to negotiate a new connection for each request to the server.
HTTP Compression	Compresses HTTP responses sent from the servers to compression-aware browsers. The smaller responses reduce download time and save bandwidth.
Integrated Caching	Stores responses to client requests. Subsequent requests for the same content are served from the NetScaler cache instead of being forwarded to the origin server.
Front End Optimization	Reduces the load and render time of web pages by simplifying and optimizing the content served to the client browser. Note: Supported from NetScaler 10.5 onwards.
Content Accelerator	Stores server responses on a Citrix ByteMobile T2100 appliance. Note: Supported from NetScaler 10.1 onwards.
SPDY (Speedy)	Acts as a SPDY gateway between clients and your servers, providing SPDY support without the need to configure/upgrade SPDY on the servers. Note: Supported from NetScaler 10.1 onwards.

Client Keep-Alive

Aug 06, 2014

The client keep-alive feature enables multiple client requests to be sent on a single client connection. This feature helps in a transaction management environment where typically the server closes the client connection after serving the response. The client then opens a new connection for each request and spends more time on the transaction.

Client keep-alive resolves this issue by keeping the connection between the client and the appliance (client-side connection) open even after the server closes the connection with the appliance. This allows sending multiple client requests using a single connection and saves the round trips associated with opening and closing a connection. Client keep-alive is most beneficial in SSL sessions.

Client keep-alive is also useful under either of the following conditions:

- When the server does not support client keep-alive.
- When the server supports client keep-alive but an application on the server does not support client keep-alive.

Note: Client keep-alive is applicable for HTTP and SSL traffic.
Client-keep alive can be configured globally to be able to handle all traffic. It can also be configured to be active only on specific services.

In client keep-alive environment, the configured services intercept the client traffic and the client request is directed to the origin server. The server sends the response and closes the connection between the server and the appliance. If a "Connection: Close" header is present in the server response, the appliance corrupts this header in the client-side response, and the client-side connection is kept open. As a result, the client does not have to open a new connection for the next request; instead, the connection to the server is reopened.

Note: If a server sends back two "Connection: Close" headers, only one is edited. This results in significant delays on the client rendering of the object because a client does not assume that the object has been delivered completely until the connection is actually closed.

Configuring Client Keep-Alive

Updated: 2014-08-12

Client keep-alive, by default, is disabled on the NetScaler, both globally and at service level. Therefore, you must enable the feature at the required scope.

Note: If you enable client keep-alive globally, it is enabled for all services, regardless of whether you enable it at the service level.
Additionally, if required, you can configure some HTTP parameters to specify the maximum number of HTTP connections retained in the connection reuse pool, enable connection multiplexing, and enable persistence Etag.

Note: When Persistent ETag is enabled, the ETag header includes information about the server that served the content. This ensures that cache validation conditional requests or browser requests, for that content, always reaches the same server.

To configure client keep-alive by using the command line interface

At the command prompt, do the following:

1. Enable client keep-alive on the NetScaler.

- At global level
  enable ns mode cka
- At service level
  set service <name> -CKA YES

  Note: Client keep-alive can be enabled only for HTTP and SSL services.

2. Configure the required HTTP parameters on the HTTP profile that is bound to the service(s).
   set ns httpProfile <name> -maxReusePool <value> -conMultiplex ENABLED -persistentETag ENABLED

   Note: Configure these parameters on the nshttp_default_profile HTTP profile, to make them available globally.

To configure client keep-alive by using the configuration utility

1. Enable client keep-alive on the NetScaler.
   - At global level
     Navigate to System > Settings, click Configure Modes and select Client side Keep Alive.
   - At service level
     Navigate to Traffic Management > Load Balancing > Services, and select the required service. In the Settings grouping, enable Client Keep-Alive.
2. Configure the required HTTP parameters on the HTTP profile that is bound to the service(s).
   Navigate to System > Profiles, and on HTTP Profiles tab, select the required profile and update the required HTTP parameters.

HTTP Compression

May 20, 2015

For websites with compressible content, the NetScaler HTTP compression feature implements lossless compression to alleviate latency, long download times, and other network-performance problems by compressing the HTTP responses sent from servers to compression-aware browsers. You can improve server performance by offloading the computationally intensive compression task from your servers to the NetScaler appliance.

The following table describes the capabilities of the HTTP compression feature:

Functionality	Description
Compression Ratio	Compression ratio depends on the types of files in the responses, but is always significant, noticeably reducing amount of data transmitted over the network.
Browser Awareness	NetScaler serves compressed data to compression aware browsers only, reducing the transaction time between the client and the server. Most modern web browsers support HTTP compression.
Compression blocking	You can define content filters to selectively block compression by applying built-in actions.
Compression Caching	With the integrated caching feature enabled, subsequent requests for the same content are served from the local cache, reducing the number of round trips to the server and improving transaction times.
HTTPS Support	Compression is particularly useful on SSL connections, because it reduces the amount of content that has to be encrypted, either on the server or by the NetScaler appliance, and decrypted by the client.
Intelligent Response Filtering	The NetScaler compression engine intelligently filters server responses on the basis of defined compression parameters. For example, the compression engine detects zero-content-length responses and compressed responses and does not compress them. The detection of compressed responses enables origin sites to use server-based compression in conjunction with the NetScaler compression feature.
Compression Switching	The NetScaler appliance transparently directs requests from compression aware clients to compression capable servers, so that responses to those clients are compressed, and responses to other clients are not delayed by compression processing.

How Compression Works

A NetScaler ADC can compress both static and dynamically generated data. It applies the GZIP or the DEFLATE compression algorithm to remove extraneous and repetitive information from the server responses and represent the original information in a more compact and efficient format. This compressed data is sent to the client's browser and

uncompressed as determined by the browser's supported algorithm or algorithms (GZIP or DEFLATE).

NetScaler compression treats static and dynamic content differently.

- Static files are compressed only once, and a compressed copy is stored in local memory. Subsequent client requests for cached files are serviced from that memory.
- Dynamic pages are dynamically created each time a client requests them.

When a client sends a request to the server:

1. The client request arrives at the NetScaler ADC. The ADC examines the headers and stores information about what kind of compression, if any, the browser supports.
2. The ADC forwards the request to the server and receives the response.
3. The NetScaler compression engine examines the server response for compressibility by matching it against policies.
4. If the response matches a policy associated with a compression action, and the client browser supports a compression algorithm specified by the action, the NetScaler ADC applies the algorithm and sends the compressed response to the client browser.
5. The client applies the supported compression algorithm to decompress the response.

Configuring HTTP Compression

Feb 13, 2017

By default, compression is disabled on the NetScaler ADC. You must enable the feature before configuring it. If the feature is enabled, the ADC compresses server requests specified by compression policies.

To configure HTTP compression, do the following:

- Enable HTTP Compression
- Configure compression actions
- Configure compression policies
- Bind the compression policies to global bind points or to virtual servers
- Optionally, configure global compression parameters

Enabling HTTP Compression

Compression can be enabled for HTTP and SSL services only. You can enable it globally, so that it applies to all HTTP and SSL services, or you can enable it just for specific services.

To enable compression by using the command line interface

At the command prompt, enter one of the following commands to enable compression globally or for a specific service:

- enable ns feature cmp
  OR
- set service <name> -CMP YES

To configure compression by using the configuration utility

Do one of the following:

- To enable compression globally, navigate to **System** > **Settings**, click **Configure Basic Features**, and select **HTTP Compression**.
- To enable compression for a specific service, navigate to **Traffic Management** > **Load Balancing** > **Services**, select the service, and click **Edit**. In the **Settings** group, click the pencil icon and enable **Compression**.

Configuring a Compression Action

A compression action specifies the action to take when a request or response matches the rule (expression) in the policy with which the action is associated. For example, you can configure a compression policy that identifies requests that will be sent to a particular server, and associate the policy with an action that compresses the server's response.

There are four built-in compression actions:

- COMPRESS: Uses the GZIP algorithm to compress data from browsers that support either GZIP or both GZIP and DEFLATE. Uses the DEFLATE algorithm to compress data from browsers that support only the DEFLATE algorithm. If the browser does not support either algorithm, the browser's response is not compressed.
- NOCOMPRESS: Does not compress data.
- GZIP: Uses the GZIP algorithm to compress data for browsers that support GZIP compression. If the browser does not support the GZIP algorithm, the browser's response is not compressed.

- DEFLATE: Uses the DEFLATE algorithm to compress data for browsers that support the DEFLATE algorithm. If the browser does not support the DEFLATE algorithm, the browser's response is not compressed. After creating an action, you associate the action with one or more compression policies.

To create a compression action by using the command line interface

At the command prompt, enter the following command to create a compression action:

add cmp action <name> <cmpType> [-addVaryHeader <addVaryHeader> -varyHeaderValue <string>]

To create a compression action by using the configuration utility

Navigate to **Optimization** > **HTTP Compression** > **Actions** , click **Add** , and create a compression action to specify the type of compression to be performed on the HTTP response.

Configuring a Compression Policy

A compression policy contains a rule, which is a logical expression that enables the NetScaler appliance to identify the traffic that should be compressed.

When the NetScaler ADC receives an HTTP response from a server, it evaluates the built-in compression policies and any custom compression policies to determine whether to compress the response and, if so, the type of compression to apply. Priorities assigned to the policies determine the order in which the policies are matched against the requests.

The following table lists the built-in HTTP compression policies. These policies are activated globally when you enable compression.

Built-in Classic or Default Syntax Policy	**Description**
ns_nocmp_mozilla_47 ns_adv_nocmp_mozilla_47	Prevents compression of CSS files when a request is sent from a Mozilla 4.7 browser.
ns_cmp_mscss ns_adv_cmp_mscss	Compresses CSS files when the request is sent from a Microsoft Internet Explorer browser.
ns_cmp_msapp ns_adv_cmp_msapp	Compresses files that are generated by the following applications:s • Microsoft Office Word • Microsoft Office Excel • Microsoft Office PowerPoint
ns_cmp_content_type ns_adv_cmp_content_type	Compresses data when the response containsContent-Type header and contains text.
ns_nocmp_xml_ie	Prevents compression when a request is sent, from a Microsoft Internet Explorer

Built-in Classic or Default Syntax Policy	Description
ns_adv_nocmp_xml_ie	browser and the response contains a Content-Type header and contains text or xml.

To create a compression policy by using the command line interface

At the command prompt, enter the following command to create a compression policy:

add cmp policy <name> -rule <expression> -resAction <string>

To create a compression policy by using the configuration utility

Navigate to **Optimization** > **HTTP Compression** > **Policies** , click **Add** , and create a compression policy by specifying the condition and the corresponding action to be executed.

Binding a Compression Policy

To put a compression policy into effect, you must bind it either globally, so that it applies to all traffic that flows through the NetScaler ADC, or to a specific virtual server, so that the policy applies only to requests whose destination is the VIP address of that virtual server.

When you bind a policy, you assign it a priority. The priority determines the order in which the policies you define are evaluated. You can set the priority to any positive integer.

To bind a compression policy by using the command line interface

At the command prompt, enter one of the following commands to bind a compression policy globally or to a specific virtual server:

- bind cmp global <policyName> [-priority <positive_integer>] [-state (ENABLED | DISABLED)]...
- bind lb vserver <vserverName> -policyName <policyName> -priority <positive_integer>. Repeat this command for each virtual server to which you want to bind the compression policy.

To bind a compression policy by using the configuration utility

Do one of the following:

- At global level Navigate to **Optimization** > **HTTP Compression** > **Policies**, click **Policy Manager** and bind the required policies by specifying the relevant **Bind Point** and **Connection Type** (Request/Response).
- At virtual server level
  - For load balancing virtual server, Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, select the required virtual server, click **Policies**, and bind the relevant policy.
  - For content switching **virtual server**, Navigate to **Traffic Management** > **Content Switching** > **Virtual Servers**, select the required virtual server, click **Policies**, and bind the relevant policy.

Setting the Global Compression Parameters for Optimal Performance

Many users accept the default values for the global compression parameters, but you might be able to provide more effective compression by customizing these settings.

Note: After you configure the global compression parameters, you do not have to reboot your appliance. They get applied to the new flows immediately.

The following table describes the compression parameters that you can set on the NetScaler ADC.

Compression Parameters	Description
Quantum size	Size, in KB, of the buffer maintained for accumulating server responses. The responses are compressed when the buffer size exceeds this value. For example, if you set the quantum size to 50 KB, the NetScaler ADC compresses the buffer's contents when its size becomes larger than 50 KB. Minimum value: 1. Maximum value: 63488. Default: 57344.
Compression level	Level of compression to apply to server responses. Possible values: Best Speed, Best Compression, optimal.
Minimum HTTP response size	Minimum size, in bytes, of an HTTP response that is compressed. Responses smaller than the value specified by this parameter are sent without being compressed.
Bypass compression on CPU usage	NetScaler CPU usage, as a percentage, at or above which no compression is done. Default: 100.
Policy Type*	Type of policies used for compression. Possible values: Classic, Default Syntax. Default: Classic.
Allow Server-side compression	Allow servers to send compressed data to the NetScaler ADC.
Compress push packet	Upon receipt of a packet with a TCP PUSH flag, compress the accumulated packets immediately, without waiting for the quantum buffer to be filled.
External Cache	Issue a private response directive indicating that the response message is intended for a single user and must not be cached by a shared or proxy cache.

To configure global compression parameters by using the command line interface

At the command prompt, enter the following command to configure compression parameters that apply globally:

set cmp parameter -cmpLevel <cmpLevel> -quantumSize <integer> [-addVaryHeader (ENABLED | DISABLED) [-varyHeaderValue <string>]]...

Note: Vary header parameters are available from NetScaler 10.5 onwards.

To configure global compression parameters by using the configuration utility

Navigate to **Optimization** > **HTTP Compression** , click **Change Compression Settings** , and set the relevant parameters.

Evaluating Your Compression Configuration

Apr 20, 2015

You can view the compression statistics in the dashboard utility or in an SNMP monitor. The dashboard utility displays summary and detailed statistics in a tabular and graphic format.

Optionally, you can also view statistics for a compression policy, including the number of hits that the policy counter increments during the policy based compression.

Note:

- For more information about the statistics and charts, see the Dashboard help on the Citrix NetScaler appliance.
- For more information about SNMP, see SNMP.

To View Compression Statistics by Using the Command Line Interface

At the command prompt, enter the following commands to display the compression statistics:

1. To display compression statistics summary
   stat cmp
   Note: The stat cmp policy command displays statistics for default syntax compression policies only.
2. To display compression policy hits and details
   show cmp policy <name>
3. To display detailed compression statistics
   stat cmp -detail

To View Compression Statistics by Using the Dashboard

In the Dashboard utility, you can display the following types of compression statistics:

- Select Compression to display a summary of the compression statistics.
- To display detailed compression statistics by protocol type, click the Details
- To display the rate of requests processed by the compression feature, click the Graphical View tab.

To View Compression Statistics by Using SNMP

You can view the following compression statistics by using the SNMP network management application.

- Number of compression requests (OID: 1.3.6.1.4.1.5951.4.1.1.50.1)
- Number of compressed bytes transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.2)
- Number of compressible bytes received (OID: 1.3.6.1.4.1.5951.4.1.1.50.3)
- Number of compressible packets transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.4)
- Number of compressible packets received (OID: 1.3.6.1.4.1.5951.4.1.1.50.5)
- Ratio of compressible data received and compressed data transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.6)
- Ratio of total data received to total data transmitted (OID: 1.3.6.1.4.1.5951.4.1.1.50.7)

To View Additional Compression Statistics by Using the Configuration Utility

1. To display HTTP compression statistics:
   Navigate toOptimization > HTTP Compression and click Statistics.
2. To display statistics of a compression policy
   Navigate to Optimization > HTTP Compression > Policies> select the policy, and click Statistics.
3. To display statistics of a compression policy label

Navigate to Optimization > HTTP Compression > Policies> select a policy label, and click Statistics.

Offloading HTTP Compression to the NetScaler ADC

Nov 04, 2015

Performing compression on a server can affect the server's performance. A NetScaler ADC placed in front of your web servers and configured for HTTP compression offloads compression of both static and dynamic content, saving server CPU cycles and resources.

You can offload compression from the Web servers in either of two ways:

- Disable compression on the web servers, enable the NetScaler Compression feature at a global level, and configure services for compression.
- Leave the compression feature enabled on the web servers and configure the NetScaler appliance to remove the "Accept Encoding" header from all HTTP client requests. The servers then send uncompressed responses. The NetScaler ADC compresses the server responses before sending them to the clients.

Note: The second option does not work if the servers automatically compress all responses. The NetScaler ADC does not attempt to compress a response that is already compressed.

The Servercmp parameter enables the Netscaler appliance to handle offload HTTP compression. By default, this parameter is set ON for the server to send compressed data to the Netscaler appliance. To offload HTTP compression, you need to set the servercmp parameter to OFF. At the command prompt, enter the following commands:

set service <service name> -CMP YES

Repeat this command for each service for which you want to enable compression.

show service <service name>

Repeat this command for each service, to verify that compression is enabled.

Save config

set cmp parameter –serverCmp OFF

Integrated Caching

Aug 25, 2016

The integrated cache provides in-memory storage on the Citrix NetScaler appliance and serves Web content to users without requiring a round trip to an origin server. For static content, the integrated cache requires little initial setup. After you enable the integrated cache feature and perform basic setup (for example, determining the amount of NetScaler appliance memory the cache is permitted to use), the integrated cache uses built-in policies to store and serve specific types of static content, including simple Web pages and image files. You can also configure the integrated cache to store and serve dynamic content that is usually marked as non-cacheable by Web and application servers (for example, database records and stock quotes).

Note: The term Integrated Cache can be interchangeably used with AppCache; note that from a functionality point of view, both terms mean the same.

When a request or response matches the rule (logical expression) specified in a built-in policy or a policy that you have created, the NetScaler appliance performs the action associated with the policy. By default, all policies store cached objects in and retrieve them from the Default content group, but you can create your own content groups for different types of content.

To enable the NetScaler appliance to find cached objects in a content group, you can configure selectors, which match cached objects against expressions, or you can specify parameters for finding objects in the content group. If you use selectors (which Citrix recommends), configure them first, so that you can specify selectors when you configure content groups. Next, set up any content groups that you want to add, so that they are available when you configure the policies. To complete the initial configuration, create policy banks by binding each policy to a global bind point or a virtual server, or to a label that can be called from other policy banks.

You can tune the performance of the integrated cache, using methods such as pre-loading cached objects before they are scheduled to expire. To manage the handling of cached data once it leaves the NetScaler appliance, you can configure caching-related headers that are inserted into responses. The integrated cache can also act as a forward proxy for other cache servers.

Note: Integrated caching requires some familiarity with HTTP requests and responses. For information about the structure of HTTP data, see *Live HTTP Headers* at "http://livehttpheaders.mozdev.org/."

How the Integrated Cache Works

Sep 04, 2015

The integrated cache monitors HTTP and SQL requests that flow through the Citrix NetScaler appliance and compares the requests with stored policies. Depending on the outcome, the integrated cache feature either searches the cache for the response or forwards the request to the origin server. For HTTP requests, the integrated cache feature can also serve partial content from the cache in response to single byte-range and multi-part byte-range requests.

Cached data can be compressed if the client accepts compressed content. You can configure expiration times for a content group, and you can selectively expire entries in a content group.

Data that is served from the integrated cache is a cache hit, and data served from the origin is a cache miss, as described in the following table.

Table 1. Cache Hits and Misses

Transaction Type	Specifies
Cache Hit	Responses that the NetScaler appliance serves from the cache, including: • Static objects, for example, image files and static Web pages • 200 OK pages • 203 Non-Authoritative Response pages • 300 Multiple Choices pages • 301 Moved Permanently pages • 302 Found pages • 304 Not Modified pages These responses are known as positive responses. The NetScaler appliance also caches the following negative responses: • 307 Temporary Redirect pages • 403 Forbidden pages • 404 Not Found pages • 410 Gone pages To further improve performance, you can configure the NetScaler appliance to cache additional types of content.
Storable Cache Miss	For a storable cache miss, the NetScaler appliance fetches the response from the origin server, and stores the response in the cache before serving it to the client.
Non-Storable Cache Miss	A non-storable cache miss is inappropriate for caching. By default, any response that contains the following status codes is a non-storable cache miss:

Transaction Type	**Specifies** • 201, 202, 204, 205, 206 status codes • All 4xx codes, except 403, 404 and 410 • 5xx status codes

Note: To integrate dynamic caching with your application infrastructure, use the NITRO API to issue cache commands remotely. For example, you can configure triggers that expire cached responses when a database table is updated.
To ensure the synchronization of cached responses with the data on the origin server, you configure expiration methods. When the NetScaler appliance receives a request that matches an expired response, it refreshes the response from the origin server.

Note: Citrix recommends that you synchronize the times on the NetScaler appliance and the back-end server(s).

Example of Dynamic Caching

Sep 11, 2014

Dynamic caching evaluates HTTP requests and responses based on parameter-value pairs, strings, string patterns, or other data. For example, suppose that a user searches for Bug 31231 in a bug reporting application. The browser sends the following request on the user's behalf:

```
GET /mybugreportingsystem/mybugreport.dll?IssuePage&RecordId=31231&Template=view&TableId=1000
Host: mycompany.net
User-Agent: Mozilla/5.0 (Windows; U; Windows NT 5.1; en-US; rv:1.9) Gecko/2008052906 Firefox/3.0
Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q=0.8
Accept-Language: en-us,en;q=0.5
. . .
```

In this example, GET requests for this bug reporting application always contain the following parameters:

- IssuePage
- RecordID
- Template
- TableId

GET requests do not update or alter the data, so you can configure these parameters in caching policies and selectors, as follows:

- You configure a caching policy that looks for the string mybugreportingsystem and the GET method in HTTP requests. This policy directs matching requests to a content group for bugs.
- In the content group for bugs, you configure a hit selector that matches various parameter-value pairs, including IssuePage, RecordID, and so on.

Note that a browser can send multiple GET requests based on one user action. The following is a series of three separate GET requests that a browser issues when a user searches for a bug based on a bug ID.

```
GET /mybugreportingsystem/mybugreport.dll?IssuePage&RecordId=31231&Template=view&TableId=1000
GET /mybugreportingsystem/mybugreport.dll?IssuePage&Template=viewbtns&RecordId=31231&TableId=1000
GET /mybugreportingsystem/mybugreport.dll?IssuePage&Template=viewbody&RecordId=31231&tableid=1000
```

To fulfill these requests, multiple responses are sent to the user's browser, and the Web page that the user sees is an assembly of the responses.

If a user updates a bug report, the corresponding responses in the cache should be refreshed with data from the origin server. The bug reporting application issues HTTP POST requests when a user updates a bug report. In this example, you configure the following to ensure that POST requests trigger invalidation in the cache:

- A request-time invalidation policy that looks for the string mybugreportingsystem and the POST HTTP request method, and directs matching requests to the content group for bug reports.
- An invalidation selector for the content group for bug reports that expires cached content based on the RecordID parameter. This parameter appears in all of the responses, so the invalidation selector can expire all relevant items in the cache.

The following excerpt shows a POST request that updates the sample bug report.

```
POST /mybugreportingsystem/mybugreport.dll?TransitionForm HTTP/1.1\r\n
User-Agent: Mozilla/4.0 (compatible; MSIE 6.0; Windows NT 5.0) Opera 7.23 [en]\r\n
Host: mybugreportingsystem\r\n
Cookie:ttSearch.134=%23options%3Afalse%23active%23owner%3Afalse%23unowned%3Afalse%23submitter%3Afalse%23incsub%3Atrue;
Cookie2: $Version=1\r\n
. . .
\r\n
ProjectId=2&RecordId=31231&TableId=1000&TransitionId=1&Action=Update&CopyProjectId=0&ReloadForm=0&State=&RecordLockId=49873+issues+in+HTTP&F43. . .
```

When the Citrix NetScaler appliance receives this request, it does the following:

- Matches the request with an invalidation policy.
- Finds the content group that is named in the policy.
- Applies the invalidation selector for this content group and expires all responses that match RecordID=31231.

When a user issues a new request for this bug report, the NetScaler appliance goes to the origin server for updated copies of all the responses that are associated with the report instance, stores the responses in the content group, and serves them to the user's browser, which reassembles the report and displays it.

Setting Up the Integrated Cache

Dec 04, 2017

To use the integrated cache, you must install the license and enable the feature. After you enable the integrated cache, the Citrix® NetScaler® appliance automatically caches static objects as specified by built-in policies and generates statistics on cache behavior. (Built-in policies have an underscore in the initial position of the policy name.)

Even if the built-in policies are adequate for your situation, you might want to modify the global attributes. For example, you might want to modify the amount of NetScaler appliance memory allocated to the integrated cache.

If you would like to observe cache operation before changing settings, see "Displaying Cached Objects and Cache Statistics."

Note: The NetScaler cache is an in-memory store that is purged when you restart the appliance.
This section includes the following details:

- Installing the Integrated Cache License
- Enabling Integrated Caching
- Configuring Global Attributes for Caching
- Built-in Content Group, Pattern Set, and Policies for the Integrated Cache

Installing the Integrated Cache License

Updated: 2013-10-28

An integrated cache license is required. For information about licenses, see information about obtaining NetScaler licenses at "http://support.citrix.com/article/ctx121062."

To install the license for the Integrated Caching feature

1. Obtain a license code from Citrix, go to the command line interface, and log in.
2. At the command line interface, copy the license file to the /nsconfig/license folder.
3. Reboot the NetScaler appliance by using the following command:

```
reboot
```

Enabling Integrated Caching

Updated: 2015-05-20

When you enable integrated caching, the NetScaler appliance begins caching server responses. If you have not configured any policies or content groups, the built in policies store cached objects in the Default content group.

To enable integrated caching by using the command line interface

At the command prompt, type one of the following commands to enable or disable integrated caching:

```
enable ns feature IC
```

To enable integrated caching by using the configuration utility

Navigate to System > Settings, click Configure Basic Features, and select Integrated Caching.

Configuring Global Attributes for Caching

Updated: 2014-08-08

Global attributes apply to all cached data. You can specify the amount of NetScaler memory allocated to the integrated cache, Via header insertion, a criterion for verifying that a cached object should be served, the maximum length of a POST body permitted in the cache, whether to bypass policy evaluation for HTTP GET requests, and an action to take when a policy cannot be evaluated.

The cache memory capacity is limited only by the memory of the hardware appliance. Also, any packet engine (the central distribution hub of all incoming TCP requests) in the nCore NetScaler appliance is aware of objects cached by other packet engines in the nCore NetScaler appliance.

Note: When the default global memory limit is set as 0 and the Integrated Caching (IC) feature is enabled, the appliance does not cache any objects. For caching, you must explicitly configure the global memory limit. However, if you enable "set aaa parameter enableStaticPageCaching" option, there will be some default memory configured in the appliance. This memory is insufficient for caching large Objects and so it is necessary to assign a higher memory limit for IC. You can perform this by configuring the "set cache parameter –memLimit" command. The new setting is applied only after you save the configuration and reboot the appliance.

You can modify the global memory limit configured for caching objects. However, when you update the global memory limit to a value lower than the existing value (for example, from 10 GB to 4 GB), if a higher amount of memory (greater than 4 GB) is already being used to cache objects, the NetScaler continues using that amount of memory.

This means that even though the integrated caching limit is configured to some value, the actual limit used can be higher. This excessive memory is however released when the objects are removed from cache.

The output of the show cache parameter command indicates the configured value (Memory Usage limit) and the actual value being used (Memory usage limit (active value)).

To configure global settings for caching by using the command line interface

At the command prompt, type:

set cache parameter [-memLimit <MBytes>] [-via <string>] [-verifyUsing <criterion>] [-maxPostLen <positiveInteger>] [-prefetchMaxPending <positiveInteger>] [-enableBypass (YES | NO)] [-undefAction (NOCACHE | RESET)]

To configure global settings for caching by using the configuration utility

Navigate to Optimization > Integrated Caching, click Change Cache Settings, and configure the global settings for caching.

Built-in Content Group, Pattern Set, and Policies for the Integrated Cache

Updated: 2013-08-23

The Citrix NetScaler appliance includes a built-in integrated caching configuration that you can use for caching content. The configuration consists of a content group called ctx_cg_poc, a pattern set called ctx_file_extensions, and a set of integrated cache policies. In the content group ctx_cg_poc, only objects that are 500 KB or smaller are cached. The content is cached for 86000 seconds, and the memory limit for the content group is 512 MB. The pattern set is an indexed array of common file extensions for file-type matching.

The following table lists the built-in integrated caching policies. By default, the policies are not bound to any bind point. You must bind them to a bind point if you want the NetScaler appliance to evaluate traffic against the policies. The policies cache objects in the ctx_cg_poc content group.

Table 1. Built-in Integrated Caching Policies

Integrated caching policy name	Policy rule	Policy action	Description
_cacheVPNStaticObjects	HTTP.REQ.URL.SET_TEXT_MODE(IGNORECASE).CONTAINS_INDEX(\"ctx_file_extensions\").BETWEEN(101,150)	CACHE	Check whether the requested file is an image file (by comparing the extension of the requested object with the extensions in ctx_file_extensions, indexes 101 through 150) and then cache the file.
_cacheTCPVPNStaticObjects	HTTP.REQ.URL.ENDSWITH(\".css\")	CACHE	Cache all cascading style sheet content.
_cacheOCVPNStaticObjects	HTTP.REQ.URL.ENDSWITH(\".pdf\")	CACHE	Cache all PDF content.
_cacheWFStaticObjects	HTTP.REQ.URL.ENDSWITH(\".js\")	CACHE	Cache all JSS content.

Integrated caching policy name	Policy rule	Policy action	Description
_imgNoCacheReq	HTTP.RES.HEADER(\"Content-Type\").CONTAINS(\"application/x-javascript\")	CACHE	Cache all JavaScript content.
_noCacheRest	TRUE	NOCACHE	Do not cache any content.

Configuring Selectors and Basic Content Groups

Aug 26, 2013

You can configure selectors and apply them to content groups. When you add a selector to one or more content groups, you specify whether the selector is to be used for identifying cache hits or identifying cached objects to be invalidated (expired). Selectors are optional. Alternatively, you can configure content groups to use hit parameters and invalidation parameters. However, Citrix recommends that you configure selectors.

After configuring selectors, or deciding to use parameters instead, you are ready to set up a basic content group. After creating the basic content group, you need to decide how objects should be expired from the cache, and configure cache expiration. You can further modify the cache as described in "Improving Cache Performance" and "Configuring Cookies, Headers, and Polling", but you might first want to configure caching policies.

Note: Content group parameters and selectors are used only at request time, and you typically associate them with policies that use MAY_CACHE or MAY_NOCACHE actions.

Advantages of Selectors

Oct 28, 2013

A selector is a filter that locates particular objects in a content group. If you do not configure a selector, the Citrix® NetScaler® appliance looks for an exact match in the content group. This can lead to multiple copies of the same object residing in a content group. For example, a content group that does not have a selector may need to store URLs for host1.domain.com\mypage.htm, host2.domain.com\mypage.htm, and host3.domain.com\mypage.htm. In contrast, a selector can match just the URL (mypage.html, using the expression http.req.url) and the domain (.com, using the expression http.req.hostname.domain), allowing the requests to be satisfied by the same URL.

Selector expressions can perform simple matching of parameters (for example, to find objects that match a few query string parameters and their values). A selector expression can use Boolean logic, arithmetic operations, and combinations of attributes to identify objects (for example, segments of a URL stem, a query string, a string in a POST request body, a string in an HTTP header, a cookie). Selectors can also perform programmatic functions to analyze information in a request. For example, a selector can extract text in a POST body, convert the text into a list, and extract a specific item from the list.

For more information about expressions and what you can specify in an expression, see "Policies and Expressions."

Using Parameters Instead of Selectors

Jul 10, 2013

Although Citrix recommends the use of selectors with a content group, you can instead configure hit parameters and invalidation parameters. For example, suppose that you configure three hit parameters in a content group for bug reports: BugID, Issuer, and Assignee. If a request contains BugID=456, with Issuer=RohitV and Assignee=Robert, the NetScaler appliance can serve responses that match these parameter-value pairs.

Invalidation parameters in a content group expire cached entries. For example, suppose that BugID is ab invalidation parameter and a user issues a POST request to update a bug report. An invalidation policy directs the request to this content group, and the invalidation parameter for the content group expires all cached responses that match the BugID value. (The next time a user issues a GET request for this report, a caching policy can enable the NetScaler appliance to refresh the cached entry for the report from the origin server.)

Note that the same parameter can be used as a hit parameter or an invalidation parameter.

Content groups extract request parameters in the following order:

- URL query
- POST body
- Cookie header

After the first occurrence of a parameter, regardless of where it occurred in the request, all its subsequent occurrences are ignored. For example, if a parameter exists both in the URL query and in the POST body, only the one in the URL query is considered.

If you decide to use hit and invalidation parameters for a content group, configure the parameters when you configure the content group.

Note: Citrix recommends that you use selectors rather than parameterized content groups, because selectors are more flexible and can be adapted to more types of data.

Configuring a Selector

Aug 07, 2014

A content group can use a hit selector to retrieve cache hits or use an invalidation selector to expired cached objects and fetch new ones from the origin server.

A selector contains a name and a logical expression, called an *advanced expression*.

For more information about advanced expressions, see "Policies and Expressions."

To configure a selector, you assign it a name and enter one or more expressions. As a best practice, a selector expression should include the URL stem and host, unless there is a strong reason to omit them.

To configure a selector by using the command line interface

At the command prompt, type:

add cache selector <selectorName> (<rule> ...)
For information about configuring the expression or expressions, see "To configure a selector expression by using the command line interface."

Examples

```
>add cache selector product_selector "http.req.url.query.value(\"ProductId\")" "http.req.url.query.value(\"BatchNum\")" "http.req.url.query.value(\"depotLocation\")"
> add cache selector batch_selector "http.req.url.query.value(\"ProductId\")" "http.req.url.query.value(\"BatchId\")" "http.req.url.query.value(\"depotLocation\")"
> add cache selector product_id_selector "http.req.url.query.value(\"ProductId\")"
> add cache selector batchnum_selector "http.req.url.query.value(\"BatchNum\")" "http.req.url.query.value(\"depotLocation\")"
> add cache selector batchid_selector "http.req.url.query.value(\"depotLocation\")" "http.req.url.query.value(\"BatchId\")"
```

To configure a selector by using the configuration utility

Navigate to Optimization > Integrated Caching > Cache Selectors, and add the cache selector.

About Content Groups

Mar 16, 2012

A content group is a container for cached objects that can be served in a response. When you first enable the integrated cache, cacheable objects are stored in a content group named Default. You can create new content groups that have unique properties. For example, you can define separate content groups for image data, bug reports, and stock quotes, and you can configure the stock quote content group to be refreshed more often than the other groups.

You can configure expiration of an entire content group or selected entries in a content group.

The data in a content group can be static or dynamic, as follows:

- **Static content groups**. Finds an exact match between the URL stem and host name on the request and the URL stem and host name of the response.
- **Dynamic content groups**. Looks for objects that contains particular parameter-value pairs, arbitrary strings, or string patterns. Dynamic content groups are useful when caching data that is updated frequently (for example, a bug report or a stock quote).

1. A user enters search criteria for an item, such as a bug report, and clicks the Find button in an HTML form.
2. The browser issues one or more HTTP GET requests. These requests contain parameters (for example, the bug owner, bug ID, and so on).
3. When the NetScaler appliance receives the requests, it searches for a matching policy, and if it finds a caching policy that matches these requests, it directs the requests to a content group.
4. The content group looks for appropriate objects in the content group, usually based on criteria that you configure in a selector.
   For example, the content group can retrieve responses that match NameField=username and BugID=ID.
5. If it finds matching objects, the NetScaler appliance can serve them to the user's browser, where they are assembled into a complete response (for example, a bug report).

1. A user modifies data (for example, the user modifies the bug report and clicks the Submit button).
2. The browser sends this data in the form of one or more HTTP requests. For example, it can send a bug report in the form of several HTTP POST requests that contain information about the bug owner and bug ID.
3. The NetScaler appliance matches the requests against invalidation policies. Typically, these policies are configured to detect the HTTP POST method.
4. If the request matches an invalidation policy, the NetScaler appliance searches the content group that is associated with this policy, and expires responses that match the configured criteria for invalidation.
   For example, an invalidation selector can find responses that match NameField=username and BugID=ID.
5. The next time the NetScaler appliance receives a GET request for these responses, it fetches refreshed versions from the origin server, caches the refreshed responses, and serves these responses to the user's browser, where they are assembled into a complete bug report.

Setting Up a Basic Content Group

Aug 07, 2014

By default, all cached data is stored in the default content group. You can configure additional content groups and specify these content groups in one or more policies.

You can configure content groups for static content, and you must configure content groups for dynamic content. You can modify the configuration of any content group, including the default group.

At the command prompt, type:

add cache contentgroup <name> (-hitSelector <hitSelectorName> -invalSelector <invalidationSelectorName> | -hitParams <hitParamName> -invalParams <invalidationParamName>) -type <type> [-relExpiry <sec> | -relExpiryMilliSec <msec>] [-heurExpiryParam <positiveInteger>]

Examples

> add cache contentgroup Products_Details –hitSelector product_selector –invalSelector id_selector
> add cache contentgroup bugrep -hitParams IssuePage RecordID Template TableId -invalParams RecordID -relExpiry 864000

Navigate to Optimization > Integrated Caching > Content Groups, and create the content group.

Expiring or Flushing Cached Objects

Oct 28, 2013

If a response does not have an Expires header or a Cache-Control header with an expiration time (Max-Age or Smax-Age), you must expire objects in a content group by using one of the following methods:

- Configure content group expiration settings to determine whether and how long to keep the object.
- Configure an invalidation policy and action for the content group. For more information, see "Configuring Policies for Caching and Invalidation."
- Expire the content group or objects within it manually.

After a cached response expires, the NetScaler appliance refreshes it the next time the client issues a request for the response. By default, when the cache is full, the NetScaler appliance replaces the least recently used response first.

The following list describes methods for expiring cached responses using settings for a content group. Typically, these methods are specified as a percent or in seconds:

- **Manual**. Manually invalidate all responses in a content group or all responses in the cache.
- **Response-based**. Specific expiration intervals for positive and negative responses. Response-based expiry is considered only if the Last-Modified header is missing in the response.
- **Heuristic expiry**. For responses that have a Last-Modified header, heuristic expiry is a percentage of the time since the response was modified (calculated as current time minus the Last-Modified time, multiplied by the heuristic expiry value). For example, if a Last-Modified header indicates that a response was updated 2 hours ago, and the heuristic expiry setting is 10%, cached objects expire after 0.2 hours. This method assumes that frequently updated responses need to be expired more often.
- **Absolute or relative**. Specify an exact (absolute) time when the response expires every day, in HH:MM format, local time or GMT. Local time may not work in all time zones.
  Relative expiration specifies a number of seconds or milliseconds from the time a cache miss causes a trip to the origin server to the expiration of the response. If you specify relative expiration in milliseconds, enter a multiple of 10. This form of expiration works for all positive responses. Last-Modified, Expires, and Cache-Control headers in the response are ignored.

  Absolute and relative expiration override any expiration information in the response itself.

- **On download**. The option Expire After Complete Response Received expires a response as soon as it is downloaded. This is useful for frequently updated responses, for example, stock quotes. By default, this option is disabled.
  Enabling both Flash Cache and Expire After Complete Response Received accelerates the performance of dynamic applications. When you enable both options, the NetScaler appliance fetches only one response for a block of simultaneous requests.

- **Pinned**. By default, when the cache is full the NetScaler appliance replaces the least recently used response first. The NetScaler appliance does not apply this behavior to content groups that are marked as pinned.

If you do not configure expiration settings for a content group, the following are additional options for expiring objects in the group:

- Configure a policy with an INVAL action that applies to the content group.
- Enter the names of content groups when configuring a policy that uses an INVAL action.

Expiration works differently for positive and negative responses. Positive and negative responses are described in the table, *Expiration of Positive and Negative Responses* mentioned below.

The following are rules of thumb for understanding the expiration method that is applied to a content group:

- You can control whether the NetScaler appliance evaluates response headers when deciding whether to expire an object.
- Absolute and relative expiration cause the NetScaler appliance to ignore the response headers (they override any expiration information in the response).
- Heuristic expiration settings and "Weak Positive" and "Weak Negative" expiration (labeled as **Default** values in the configuration utility) cause the NetScaler appliance to examine the response headers. These settings work together as follows:
  - The value in an Expires or Cache-Control header overrides these content group settings.
  - For positive responses that lack an Expires or Cache-Control header but have a Last-Modified header, the NetScaler appliance compares heuristic expiration settings with the header value.
  - For positive responses that lack an Expires, Cache-Control, or Last-Modified header, NetScaler appliance uses the "weak positive" value.
  - For negative responses that lack an Expires or Cache-Control header, NetScaler appliance uses the "weak negative" value.

The following table describes how these methods are applied.

Table 1. Expiration of Positive and Negative Responses

Response Type	Expiration Header Type	Content Group Setting	Period the Object Remains in the Cache
Positive	any header	Expire Content After (relExpiry) with no other settings	Use the value of the Expire Content After setting.
Positive	any header	Expire Content At (absExpiry) with no other settings	Subtract current date from the value of the Expire Content At setting.
Positive	any header	Expire Content After (relExpiry) and Expire content at (absExpiry)	Use the smaller of the two values for the content group settings. See the previous rows in this table.
Positive	Last-Modified (with any other headers)	Heuristic (heurExpiry Param) with any other setting	Subtract the Last-Modified date from the current date, multiply the result by the value of the heuristic expiry setting, and then divide by 100.
Positive	Last-Modified (with	Default (positive)	Use the value of the Default (positive) expiry

Response Type	Expiration Header Type	Content Group Setting	Period the Object Remains in the Cache
	any other headers)	(weakPosRel Expiry) and no other setting	setting.
Positive	Expires or Cache-Control: Max-Age header is present Last-Modified header is absent	Heuristic (heurExpiry Param), Default (positive) (weakPosRel Expiry), or both	Subtract the current date from the Expires or the Cache-Control:Max-Age date.
Positive	no caching headers	Default (positive) (weakPosRel Expiry) and any other expiration setting.	Use the value of the Default (positive) setting.
Positive	no caching headers	Heuristic (heurExpiry Param) is present Default (positive) (weakPosRel Expiry) setting is absent	If the Last-Modified header is absent, the response is not cached or it is cached with an Already Expired status. If the Last-Modified header is present, use the heuristic expiry value.
Negative	Expires or Cache-Control:Max-Age	Expire Content After (relExpiry), Expire Content At (absExpiry), or both settings	Subtract the current date from the value of the Expires header, or use the value of the Cache-Control:Max-Age header.
Negative	Expires or Cache-Control headers are absent	Expire Content After (relExpiry), Expire Content At (absExpiry), or both settings	Response is not cached, or is cached with an Already Expired status.
Negative	Expires or Cache-Control:Max-Age	Any setting	Subtract the current date from the Expires or Cache-Control:Max-Age date.
Negative	Expires and Cache-Control:Max-Age headers are absent	Default (negative) (weakNegRel Expiry)	Use the value of the Default (negative) setting.
Negative	Expires and Cache-Control:Max-Age headers are absent	Any setting other than Default (negative) (weakNegRel Expiry)	Object is not cached or is cached with an Already Expired status.

Expiring a Content Group Manually

Aug 04, 2014

You can manually expire all of the entries in a content group.

At the command prompt, type:

expire cache contentGroup <name>

To manually expire all responses in a content group by using the configuration utility

Navigate to Optimization > Integrated Caching > Content Groups, select the content group, and click Invalidate to expire all the responses in a content group.

Navigate to Optimization > Integrated Caching > Content Groups, and click Invalidate All to expire all the responses in cache.

Configuring Periodic Expiration of a Content Group

Aug 08, 2014

You can configure a content group so that it performs selective or full expiration of its entries. The expiration interval can be fixed or relative.

At the command prompt, type:

set cache contentgroup <name> (-relExpiry | -relExpiryMilliSec | -absExpiry | -absExpiryGMT | -heurExpiryParam | -weakPosRelExpiry | -weakNegRelExpiry | -expireAtLastBye) <expirationValue>

Navigate to Optimization > Integrated Caching > Content Groups, select the content group, and specify expiry method.

Expiring a response forces the NetScaler appliance to fetch a refreshed copy from the origin server. Responses that do not have validators, for example, ETag or Last-Modified headers, cannot be revalidated. As a result, flushing these responses has the same effect as expiring them.

To expire a cached response in a content group for static data, you can specify a URL that must match the stored URL. If the cached response is part of a parameterized content group, you must specify the group name as well as the exact URL stem. The host name and the port number must be the same as in the host HTTP request header of the cached response. If the port is not specified, port 80 is assumed.

To expire individual responses in a content group by using the command line interface

At the command prompt, type:

expire cache object -url <URL> -host <hostName> [-port <port>] [-groupName <contentGroupName>] [-httpMethod GET | POST]

To expire individual responses in a content group by using the command line interface (selector-based)

At the command prompt, type the following command:

expire cache object -locator <positiveInteger>

To expire a cached response by using the configuration utility

Navigate to Optimization > Integrated Caching > Cached Objects, select the cached response, and expire.

To expire a response by using the Lookup tool (selector-based)

Navigate to Optimization > Integrated Caching > Cached Objects, click Search and, set the search criteria to find the required cached response and expire.

You can remove, or flush, all responses in a content group, some responses in a group, or all responses in the cache. Flushing

a cached response frees up memory for new cached responses.

Note: To flush responses for more than one object at a time, use the configuration utility method. The command line interface does not offer this option.

To flush responses from a content group by using the command line interface

At the command prompt, type:

flush cache contentGroup <name> [-query <queryString> | [-selectorValue <selectorExpressionIDList> -host <hostName>]]

To flush responses from a content group by using the configuration utility

1. Navigate to Optimization > Integrated Caching > Content Groups.
2. In details pane, flush the responses as follows:
   - To flush all responses in all content groups, click Invalidate All, and flush all the responses.
   - To flush responses in a particular content group, select the content group, click Invalidate, and flush all the responses.

Note: If this content group uses a selector, you can selectively flush responses by entering a string in the Selector value text box, entering a host name in the Host text box. Then click Flush and OK. The Selector value can be a query string of up to 2319 characters that is used for parameterized invalidation.
If the content group uses an invalidation parameter, you can selectively flush responses by entering a string in the Query field.

If the content group uses an invalidation parameter and Invalidate objects belonging to target host is configured, enter strings in the Query and Host fields.

To flush a cached response by using the command line interface

At the command prompt, type:

flush cache object -locator <positiveInteger> | -url <URL> -host <hostName> [-port <port>] [-groupName <contentGroupName>] [-httpMethod GET | POST]

To flush a cached response by using the configuration utility

Navigate to Optimization > Integrated Caching > Cached Objects, select the cached object, and flush.

You can remove a content group if it is not used by any policy that stores responses in the cache. If the content group is bound to a policy, you must first remove the policy. Removing the content group removes all responses stored in that group.

You cannot remove the Default, BASEFILE, or Deltajs group. The Default group stores cached responses that do not belong in any other content group.

To delete a content group by using the command line interface

At the command prompt, type:

rm cache contentgroup<name>

To delete a content group by using the configuration utility

Navigate to Optimization > Integrated Caching > Contetn Groups, select the content group, and delete.

Configuring Policies for Caching and Invalidation

Aug 30, 2013

Policies enable the integrated cache to determine whether to try to serve a response from the cache or the origin. The Citrix NetScaler appliance provides built-in policies for integrated caching, and you can configure additional policies. When you configure a policy, you associate it with an action. An action either caches the objects to which the policy applies or invalidates (expires) the objects. Typically, you based caching policies on information in GET and POST requests. You typically base invalidation policies on the presence of the POST method in requests, along with other information. You can use any information in a GET or POST request in a caching or an invalidation policy.

You can view some of the built-in policies in the integrated cache's Policies node in the configuration utility. The built-in policy names begin with an underscore (_).

Actions determine what the NetScaler appliance does when traffic matches a policy. The following actions are available:

- **Caching actions**. Policies that you associate with the CACHE action store responses in the cache and serve them from the cache.
- **Invalidation actions**. Policies that you associate with the INVAL action immediately expire cached responses and refresh them from the origin server. Note that for Web-based applications, invalidation policies often evaluate POST requests.
- **"Do not cache" actions**. Policies that you associate with a NOCACHE action never store objects in the cache.
- **"Provisionally cache" actions**. Policies that you associate with a MAYCACHE or MAYNOCACHE action depend on the outcome of additional policy evaluations.

Although the integrated cache does not store objects specified by the LOCK method, you can invalidate cached objects upon receipt of a LOCK request. For invalidation policies only, you can specify LOCK as a method by using the expression http.req.method.eq("lock"). Unlike policies for GET and POST requests, you must enclose the LOCK method in quotes because the NetScaler appliance recognizes this method name as a string only.

After you create a policy, you bind it to a particular point in the overall processing of requests and responses. Although you create a policy before binding it, you should understand how the bind points affect the order of processing before you create your policies.

The policies bound to a particular bind point constitute a policy bank. You can use goto expressions to modify the order of execution in a policy bank. You can also invoke policies in other policy banks. In addition, you can create labels and bind policies to them. Such a label is not associated with a processing point, but the policies bound to it can be invoked from other policy banks.

Actions to Associate with Integrated Caching Policies

Mar 16, 2012

The following table describes actions for integrated caching policies.

Table 1. Actions That You Can Associate with an Integrated Caching Policy

Action	Specifies
CACHE	Serves a response from the cache if the response has not expired. If the response must be fetched from the origin server, the NetScaler appliance caches the response before serving it. Even data that is updated and accessed frequently can be cached. For example, stock quotes are updated frequently, but they can be cached so that they can be served quickly to multiple users. If necessary, cached data can be refreshed immediately after it is downloaded. A CACHE action can be overridden by built-in policies.
NOCACHE	Always fetches the response from the origin server and marks the response as non-storable. You typically configure NOCACHE policies for data that is sensitive or personalized.
MAY_CACHE	Used in a request-time policy, this setting provisionally enables a response to be stored in a content group, pending evaluation of response-time policies. The following are possible: • If a matching response-time policy has a CACHE action but does not specify a content group, the response is stored in the Default group unless built-in policies override this policy. • If a matching response-time policy has a CACHE action and specifies the same content group as the one in the request-time policy, the response is stored in the named content group unless built-in policies override this policy. • If a matching response-time policy has a CACHE action but specifies a different content group from the one in the request-time policy, a NOCACHE action is applied. • If a matching response-time policy has a NOCACHE action, perform a NOCACHE action. • If there is no matching response-time policy, a CACHE action is applied, unless a built-in policy overrides this policy.
MAY_NOCACHE	For a request-time policy, this setting provisionally prevents caching the response. At response time, one of following actions is taken: • If no response-time policy matches the request, the final action is NOCACHE. • If a matching response-time policy contains a CACHE action, the final action is CACHE, unless built-in policies override this policy. • If a matching response-time policy contains a NOCACHE action, the final action is NOCACHE. • If a matching response-time policy has a CACHE action but does not specify a content group, the final action is to CACHE the response in the Default content group, unless built-in policies override this policy.

Action	Specifies
INVAL	Expires cached responses. Depending on how the policy and the content group are configured, all responses in one or more content groups are expired, or selected objects in the content group are expired. Note: You can specify INVAL actions in request-time policies only.

Bind Points for a Policy

Oct 28, 2013

You can bind the policy to one of the following bind points:

- **A global policy bank**. These are the request-time default, request-time override, response-time default, and response-time override policy banks, as described in "Order of Policy Evaluation."
- **A virtual server**. Policies that you bind to a virtual server are processed after the global override policies and before the global default policies, as described in "Order of Policy Evaluation." Note that when binding a policy to a virtual server, you bind it to either request-time or response-time processing.
- **An ad-hoc policy label**. A policy label is a name assigned to a policy bank. In addition to the global labels, the integrated cache has two built-in custom policy labels:
  - **_reqBuiltinDefaults**. This policy label, by default, is invoked from the request-time default policy bank.
  - **_resBuiltinDefaults**. This policy label, by default, is invoked from the response-time default policy bank.

  You can also define new policy labels. Policies bound to a user-defined policy label must be invoked from within a policy bank for one of the built-in bind points. For more information about creating a policy label, see "Configuring a Policy Label in the Integrated Cache." For more information about policy label invocation, see "Configuring a Policy Bank for Caching."

Important: You should bind a policy with an INVAL action to a request-time override or a response-time override bind point. To delete a policy, you must first unbind it.

For an advanced policy to take effect, you must ensure that the policy is invoked at some point during the NetScaler appliance's processing of traffic. To specify the invocation time, you associate the policy with a bind point. The following are the bind points, listed in order of evaluation:

- **Request-time override**. If a request matches a request-time override policy, by default request-time policy evaluation ends and the NetScaler appliance stores the action that is associated with the matching policy.
- **Request-time load balancing virtual server**. If policy evaluation cannot be completed after all the request-time override policies are evaluated, the NetScaler appliance processes request-time policies that are bound to load balancing virtual servers. If the request matches one of these policies, evaluation ends and the NetScaler appliance stores the action that is associated with the matching policy.
- **Request-time content switching virtual server**. Policies that are bound to this bind point are evaluated after request-time policies that are bound to load balancing virtual servers.
- **Request-time default**. If policy evaluation cannot be completed after all request-time, virtual server-specific policies are evaluated, the NetScaler appliance processes request-time default policies. If the request matches a request-time default policy, by default request-time policy evaluation ends and the NetScaler appliance stores the action that is associated with the matching policy.
- **Response-time override**. Similar to request-time override policy evaluation.
- **Response-time load balancing virtual server**. Similar to request-time virtual server policy evaluation.
- **Response-time content switching virtual server**. Similar to request-time virtual server policy evaluation.
- **Response-time default**. Similar to request-time default policy evaluation.

You can associate multiple policies with each bind point. To control the order of evaluation of the policies associated with the bind point you configure a priority level. In the absence of any other flow control information, policies are evaluated according to priority level, starting with the lowest numeric priority value.

After all integrated caching policies have been evaluated, if there are conflicting actions specified in request-time and response-time policies, the NetScaler appliance determines the final action as specified in the table, "Actions That You Can Associate with an Integrated Caching Policy."

Note: Request-time policies for POST data or cookie headers must be invoked during request-time override evaluation, because the built-in request-time policies in the integrated cache return a NOCACHE action for POST requests and a MAY_NOCACHE action for requests with cookies. Note that you would associate MAY_CACHE or MAY_NOCACHE actions with a request-time policy that points to a parameterized content group. The response time policy determines whether the transaction is stored in the cache.

Configuring a Policy in the Integrated Cache

Aug 07, 2014

You configure new policies to handle data that the built-in policies cannot process. You configure separate policies for caching, preventing caching from occurring, and for invalidating cached data. Following are the main components of a policy for integrated caching:

- Rule: A logical expression that evaluates an HTTP request or response.
- Action: You associate a policy with an action to determine what to do with a request or response that matches the policy rule.
- Content groups: You associate the policy with one or more content groups to identify where the action is to be performed.

At the command prompt, type:

add cache policy <policyName> -rule <expression> -action CACHE | MAY_CACHE | NOCACHE | MAY_NOCACHE [-storeInGroup <contentGroupName>] [-undefAction NOCACHE | RESET]

Examples

```
> add cache policy image_cache -rule "http.req.url.contains(\"jpg\") || http.req.url.contains(\"jpeg\")" -action CACHE -storeingroup myImages_group -undefaction NOCACHE
> add cache policy bugReportPolicy -rule "http.req.url.query.contains(\"IssuePage\")" -action CACHE -storeInGroup bugReportGroup
> add cache policy my_form_policy -rule "http.req.header(\"Host\")contains(\"my.company.com\") && http.req.method.eq(\"GET\") && http.req.url.query.contains(\"v=7\")" -action CACHE -storeInGroup my_
> add cache policy viewproducts_policy –rule "http.req.url.contains(\"viewproducts.aspx\")" –action CACHE -storeInGroup Product_Details
```

At the command prompt, type:

add cache policy <policyName> -rule <expression> -action INVAL [-invalObjects "<contentGroupName1>[,<selectorName1>"]. . .]] | [-invalGroup <contentGroupName1>[, <contentGroupName2>. . .]] [-undefAction NOCACHE | RESET]

Examples

```
> add cache policy invalidation_events_policy -rule "http.req.header(\"Host\")contains(\"my.company.com\") && http.req.method.eq(\"GET\") && http.req.url.query.contains(\"v=8\") -action INVAL -invalObje
> add cache policy inval_all -rule "http.req.method.eq(\"POST\") && http.req.url.contains(\"jpeg\")" -action INVAL -invalGroups myImages_group myApps_group PDF_group
> add cache policy bugReportInvalidationPolicy -rule "http.req.url.query.contains(\"TransitionForm\")" -action INVAL -invalObjects bugReport
> add cache policy editproducts_policy –rule "http.req.url.contains(\"editproducts.aspx\")" –action INVAL -invalObjects "Product_Details,batchnum_sel" "Products_In_Depots,batchid_sel"
```

Navigate to Optimization > Integrated Caching > Policies, and create the new policy.

Globally Binding an Integrated Caching Policy

Aug 08, 2014

When you globally bind a policy, it is available to all virtual servers on the NetScaler appliance.

At the command prompt, type:

bind cache global <policy> -priority <positiveInteger> [-type REQ_OVERRIDE | REQ_DEFAULT | RES_OVERRIDE | RES_DEFAULT] [-gotoPriorityExpression <expression>] [-invoke <labelType> <labelName>]

Example

```
> bind cache global myCachePolicy -priority 100 -type req_default
```

Note that the type argument is optional for globally bound policies, to maintain backward compatibility with policies that you defined using earlier versions of the NetScaler appliance. If you omit the type, the policy is bound to REQ_DEFAULT or RES_DEFAULT, depending on whether the policy rule is a response-time or a request-time expression. If the rule contains both request time and response time parameters, it is bound to RES_DEFAULT. Following is an example of a binding that omits the type.

```
> bind cache global myCache Policy 200
```

Navigate to Optimization > Integrated Caching, click Cache Policy Manager, and bind policies by specifying the relevant bind point and connection type (Request/Response).

Binding an Integrated Caching Policy to a Virtual Server

Aug 08, 2014

When you bind a policy to a virtual server, it is available only to requests and responses that match the policy and that flow through the relevant virtual server.

When using the configuration utility, you can bind the policy using the configuration dialog box for the virtual server. This enables you to view all of the policies from all NetScaler modules that are bound to this virtual server. You can also use the Policy Manager configuration dialog for the integrated cache. This enables you to view only the integrated caching policies that are bound to the virtual server.

At the command prompt, type:

- bind lb vserver <name>@ -policyName <policyName> -priority <positiveInteger> -type (REQUEST | RESPONSE)
- bind cs vserver <name>@ -policyName <policyName> -priority <positiveInteger> -type (REQUEST | RESPONSE)

- CS Virtual Server - Navigate toTraffic Management > Content Switching > Virtual Servers, select the virtual server, and bind relevant cache policies.
- LB Virtual Server - Navigate toTraffic Management > Load Balancing > Virtual Servers, select the virtual server, and bind relevant cache policies.

Navigate to Optimization > Integrated Caching, click Cache Policy Manager, and bind cache policies by specifying the relevant bind point and connection type.
Note: You can bind cache policies to both LB virtual server and CS virtual server by selecting the appropriate bind point.

Example: Caching Compressed and Uncompressed Versions of a File

Mar 16, 2012

By default, a client that can handle compression can be served uncompressed responses or compressed responses in gzip, deflate, compress, and pack200-gzip format. If the client handles compression, an Accept-Encoding:compression format header is sent in the request. The compression type accepted by the client must match the compression type of the cached object. For example, a cached .gzip file cannot be served in response to a request with an Accept-Encoding:deflate header.

A client that cannot handle compression is served a cache miss if the cached response is compressed.

For dynamic caching, you need to configure two content groups, one for compressed data and one for uncompressed versions of the same data. The following is an example of configuring the selectors, content groups, and policies for serving uncompressed files from the cache to clients that cannot handle compression, and serving compressed versions of the same files to client that can handle compression.

```
add cache selector uncompressed_response_selector http.req.url "http.req.header(\"Host\")"
add cache contentGroup uncompressed_group -hitSelector uncompressed_responst_selector -invalSelector uncomp_resp_sel
add cache policy cache_uncompressed -rule "HTTP.REQ.URL.CONTAINS(\"xyz\") && !HTTP.REQ.HEADER(\"Accept-Encoding\").EXISTS" -action CACHE -storeInGroup uncompressed_group
bind cache global cache_uncompressed -priority 100 -gotoPriorityExpression END -type REQ_OVERRIDE
add cache selector compressed_response_selector HTTP.REQ.URL "HTTP.REQ.HEADER(\"Host\")" "HTTP.REQ.HEADER(\"Accept-Encoding\")"
add cache contentGroup compressed_group -hitSelector compressed_response_selector
add cache policy cache_compressed -rule "HTTP.REQ.URL.CONTAINS(\"xyz\") && HTTP.REQ.HEADER(\"Accept-Encoding\").EXISTS" -action CACHE -storeInGroup compressed_group
bind cache global cache_compressed -priority 200 -gotoPriorityExpression END -type REQ_OVERRIDE
```

Configuring a Policy Bank for Caching

Feb 13, 2017

All of the policies that are associated with a particular bind point are collectively known as a policy bank. In addition to configuring priority levels for policies in a bank, you can modify the order of evaluation order in a bank by configuring Goto expressions. You can further modify the evaluation order by invoking an external policy bank from within the current policy bank. You can also configure new policy banks, to which you assign your own labels. Because such policy banks are not bound to any point in the processing cycle, they can be invoked only from within other policy banks. For convenience, policy banks whose labels do not correspond to a built-in bind point are called policy labels.

In addition to controlling order of policy evaluation by binding the policy and assigning a priority level, as described in "Binding Policies That Use the Default Syntax", you can establish the flow within a bank of policies by configuring a Goto expression. A Goto expression overrides the flow that is determined by the priority levels. You can also control the evaluation flow by invoking an external policy bank after evaluating an entry in the current bank. Evaluation always returns to the current bank after evaluation has completed for the external bank.

The following table summarizes the entries to control evaluation in a policy bank.

Table 1. Entries to Control Evaluation Flow in a Policy Bank

Attribute	Specifies
Name	The name of a policy, or, to invoke another policy bank without evaluating the policy, the keyword NOPOLICY. You can specify NOPOLICY more than once in a policy bank, but you can specify a named policy only once.
Priority	An integer. The lower the integer, the higher the priority.
Goto Expression	Determines the next policy or policy bank to evaluate. You can provide one of the following values: • **NEXT**: Go to the policy with the next higher priority. • **END**: Stop evaluation. • **USE_INVOCATION_RESULT**: Applicable if this entry invokes another policy bank. If the final Goto in the invoked bank has a value of END, evaluation stops. If the final Goto is anything other than END, the current policy bank performs a NEXT. • **Positive number**: Priority number of the next policy to be evaluated. • **Numeric expression**: Expression that produces the priority number of the next policy to be evaluated. The Goto can only proceed forward in a policy bank. Omitting the Goto expression is the same as specifying END.
Invocation Type	Designates a policy bank type. The value can be one of the following: • **Request Vserver**: Invokes request-time policies that are associated with a virtual server.

Attribute	Specifies
	• **Response Vserver**: Invokes response-time policies that are associated with a virtual server. • **Policy label**: Invokes another policy bank, as identified by the policy label for the bank.
Invocation Name	Name of a virtual server or a policy label, depending on the value that you specified for the Invocation Type.

The integrated cache has two built-in policy labels, and you can configure additional policy labels:

- **_reqBuiltInDefaults**: This policy label is invoked from the request-time default bind point.
- **_resBuiltInDefaults**: This policy label is invoked from the response-time default bind point.

Note: For information about creating policy labels, see "Configuring a Policy Label in the Integrated Cache."

At the command prompt, type:

bind cache policylabel <labelName> -policname<policyName> -priority<priority> [-gotoPriorityExpression <gotopriorityExpression>] [-invoke <labelType> <labelName>]

1. Navigate to Optimization > Integrated Caching, click Cache policy manager, and specify the relevant bind point (Override Global or Default Global) and connection type to view the list of policies bound to this bind point.
2. If you want to invoke a policy label without evaluating a policy, click NOPOLICY.
   Note: To invoke an external policy bank, click the field in the Invoke Type column, and select the type of policy bank that you want to invoke at this point in the policy bank. This can be a global label or a virtual server bank. In the Invoke Name field, enter the label or virtual server name. See "Entries to Control Evaluation Flow in a Policy Bank" for details.

At the command prompt, type:

- bind lb vserver <name>@ -policyName <policyName>|<NOPOLICY-CACHE> -priority <positiveInteger> -gotoPriorityExpression <expression> -type REQUEST|RESPONSE -invoke <labelType> <labelName>
- bind cs vserver <name> -policyName <policyName>|<NOPOLICY-CACHE> -priority <positiveInteger> -gotoPriorityExpression <expression> -type REQUEST|RESPONSE -invoke <labelType> <labelName>

For more information, see "Entries to Control Evaluation Flow in a Policy Bank."

1. Navigate to Traffic Management > Load Balancing/Contetn Switching > Virtual Servers, select the virtual server, and click Policies.
2. If you are configuring an existing entry in this bank, skip this step. If you are adding a new policy to this policy bank, or you want to use the “dummy” NOPOLICY entry, click Add, and do one of the following:
   - To configure a new policy, click Cache and configure the new policy as described in "Configuring a Policy in the Integrated Cache."
   - To invoke a policy bank without processing a policy a rule, select the NOPOLICY-CACHE option.

   Note: To invoke an external policy bank, click the field in the Invoke Type column, and select the type of policy bank that you want to invoke at this point in the policy bank. This can be a global label or a virtual server bank. In the Invoke Name

field, enter the label or virtual server name. See "Entries to Control Evaluation Flow in a Policy Bank" for details.

Configuring a Policy Label in the Integrated Cache

Aug 08, 2014

In addition to configuring policies in a policy bank for one of the built-in bind points or a virtual server, you can create caching policy labels and configure banks of policies for these new labels.

A policy label for the integrated cache can be invoked only from one of the bind points that you can view in the Policy Manager in the **Integrated Caching** details pane (request override, request default, response override, or response default) or the built-in policy labels _reqBuiltinDefaults and _resBuiltinDefaults. You can invoke a policy label any number of times unlike a policy, which can only be invoked once.

The configuration utility provides an option to rename a policy label. Renaming a policy label does not affect the process of evaluation of the policies bound to the label.

Note: You can use the NOPOLICY “dummy” policy to invoke any policy label from another policy bank. The NOPOLICY entry is a placeholder that does not process a rule.

At the command prompt, type the following command to create a policy label and verify the configuration:

- add cache policylabel <labelName> -evaluates (REQ | RES)
- show cache policylabel <labelName>

Invoke this policy label from a policy bank. For more information, see "Configuring a Policy Bank for Caching."

Navigate to Optimization > Integrated Caching > Policy Labels, add a policy label, and bind the cached policies.
Note: To ensure that the NetScaler ADC processes the policy label at the right time, configure an invocation of this label in one of the policy banks that are associated with the built-in bind points

Navigate to Optimization > Integrated Caching > Policy Labels, select the policy label, and rename.

Unbinding and Deleting an Integrated Caching Policy and Policy Label

Aug 08, 2014

You can unbind a policy from a policy bank, and you can delete it. To delete the policy, you must first unbind it. You can also remove a policy label invocation and delete a policy label. To delete the policy label, you must first remove any invocations that you have configured for the label.

You cannot unbind or delete the labels for the built-in bind points (request default, request override, response default, and response override).

At the command prompt, type:

unbind cache global <policy>

At the command prompt, type:

(unbind lb vserver | unbind cs vserver) <vserverName> -policyName <policyName> -type (REQUEST | RESPONSE)

At the command prompt, type:

rm cache policy <policyName>

Navigate to Optimization > Integrated Caching, click Cache Policy Manager, and unbind policies by specifying the relevant bind point and connection type (Request/Response).

1. Navigate to Optimization > Integrated Caching, click Cache policy manager, and specify the relevant bing point (LB virtual server or CS virtual server) and connection type to view the list of cache policies bound to this virtual server.
2. In the policy Invoke column, clear the entry.

Caching Support for Database Protocols

Sep 02, 2013

The integrated cache monitors database requests that flow through the Citrix® NetScaler® appliance and caches them as determined by the cache policies. Users have to configure the cache polices for MYSQL and MSSQL protocols, because the NetScaler does not provide any default policies for these protocols. When configuring the protocols, remember that request based policies currently support CACHE and INVAL actions, while response based policies currently support only NOCACHE action. After configuring the policies, bind them to virtual servers. MYSQL and MSSQL policies, both request and response, can be bound only to virtual servers

Before creating a cache policy, create a cache content group of type MYSQL or MSSQL. When you create a MYSQL or MSSQL cache content group, associate at least one hit selector with it. See "Setting Up a Basic Content Group" for setting up cache content groups.

The following example illustrates the procedure for configuring and verifying cache support for SQL protocols.

```
> enable feature IC
> set cache parameter -memlimit 100
> add cache selector sel1 mssql.req.query.text

> add cache contentgroup cg1  -type "MSSQL" -hitselector "sel1" -invalselector "inval_sel" -relExpiry "500" -maxResSize
 "100"
> add cache policy cp1  -rule "mssql.req.query.command.contains(\"select\")" -action "CACHE" -storeInGroup "cg1"
> add cache policy cp2  -invalObjects "cg1" -rule "mssql.req.query.text.contains(\"insert\")" -action "INVAL"
> add db user user1  -password "Pass1"
> add service svc_sql_1 10.102.147.70 mssql 64834 -healthMonitor "NO" -downstateflush "ENABLED"
> add lb vserver lb_mssql1 mssql 10.102.147.77 1433  -lbmethod "roundrobin"
> bind lb vserver lb_mssql1 svc_sql_1
> bind lb vserver lb_mssql1 -policyName cp1  -type "REQUEST" -priority "2"
> bind lb vserver lb_mssql1 -policyName cp2  -type "REQUEST" -priority "1"

> show cache selector sel1
    Name:sel1
    Expressions:
    1)mssql.req.query.text
> show cache policy cp1
    Name:cp1
    Rule:mssql.req.query.command.contains("select")
    CacheAction:CACHE
    Stored in group: cg1
    UndefAction:Use Global
    Hits:2
    Undef Hits:0
    Policy is bound to following entities
    1) Bound to:
      REQ VSERVER lb_mssql1
      Priority:2
      GotoPriorityExpression: END
```

Note: The methods for reducing flash crowds, as explained in "Reducing Flash Crowds", are not supported for MYSQL and MSSQL protocols.

Configuring Expressions for Caching Policies and Selectors

Oct 28, 2013

A request-time expression examines data in request-time transaction, and a response-time expression examines data in a response-time transaction. In a policy for caching, if an expression matches data in a request or response, the Citrix NetScaler appliance takes the action associated with the policy. In a selector, request-time expressions are used to find matching responses that are stored in a content group.

Before configuring policies and selectors for the integrated cache, you need to know, at minimum, the host names, paths, and IP addresses that appear in HTTP request and response URLs. And you probably need to know the format of entire HTTP requests and responses. Programs such as Live HTTP Headers (http://livehttpheaders.mozdev.org/) or HTTPFox (https://addons.mozilla.org/en-US/firefox/addon/6647) can help you investigate the structure of the HTTP data that your organization works with.

Following is an example of an HTTP GET request for a stock quote program:

```
GET /quote.dll?page=dynamic&mode=data&mode=stock&symbol=CTXS&page=multi&selected=CTXS&random=0.00792039478975548 HTTP/1.1
Host: quotes.mystockquotes.com
User-Agent: Mozilla/5.0 (Windows; U; Windows NT 5.1; en-US; rv:1.9) Gecko/2008052906 Firefox/3.0
Accept: text/html,application/xhtml+xml,application/xml;q=0.9,*/*;q=0.8
Accept-Language: en-us,en;q=0.5
Accept-Encoding: gzip,deflate,compress,pack200-gzip
Accept-Charset: ISO-8859-1,utf-8;q=0.7,*;q=0.7
Keep-Alive: 300
Connection: keep-alive
Referer: http://quotes.mystockquotes.com/quote.dll?mode=stock&symbol=CTXS&page=multi&selected=CTXS
Cookie: __qca=1210021679-72161677-10297606
```

When configuring an expression, note the following limitations:

Table 1. Restrictions on Request-Time and Response-Time Expressions

Expression Type	Restrictions
Request	Do not configure request-time expressions in a policy with a CACHE or NOCACHE action. Use MAY_CACHE or MAY_NOCACHE instead.
Response	Configure response-time expressions in caching policies only. • Selectors can use only request-time expressions. • Do not configure response-time expressions in a policy with an INVAL action. Do not configure response-time expressions in a policy with a CACHE action and a parameterized content group. Use the MAY_CACHE action.

Note: For a comprehensive discussion of advanced expressions, see "Policies and Expression."

Following are basic components of the syntax:

- Separate keywords with periods (.), as follows:
  `http.req.url`
- Enclose string values in parentheses and quotes, as follows:
  `http.req.url.query.contains("this")`
- When configuring an expression from the command line, you must escape internal quote marks (the quotes that delimit values in the

expression, as opposed to the quotes that delimit the expression). One method is to use a slash, as followings:
\"abc\"

Selector expressions are evaluated in order of appearance, and multiple expressions in a selector definition are joined by a logical AND. Unlike selector expressions, you can specify Boolean operators and modify the precedence in an advanced expression for a policy rule.

Updated: 2014-08-04

Note that on the command line, the syntax for a policy expression is somewhat different from a selector expression. For a comprehensive discussion of advanced expressions, see "Policies and Expressions."

To configure a policy expression by using the command line interface

1. Start the policy definition as described in "Globally Binding an Integrated Caching Policy."
2. To configure the policy rule, delimit the entire rule in quotes, and delimit string values within the rule in escaped quotes.

   The following is an example:

   "http.req.url.contains(\"jpg\")"
3. To add Boolean values, insert &&, | |, or ! operators.

   The following are examples:

   "http.req.url.contains(\"jpg\") || http.req.url.contains(\"jpeg\")"
   "http.req.url.query.contains(\"IssuePage\")"
   "http.req.header(\"Host\")contains(\"my.company.com\") && http.req.method.eq(\"GET\") && http.req.url.query.contains(\"v=7\")"
4. To configure an order of evaluation for the constituent parts of a compound

   "http.req.url.contains(\"jpg\") || (http.req.url.contains(\"jpeg\") && http.req.method.eq(\"GET\"))"

To configure a selector expression by using the command line interface

1. Start the selector definition as described in "About Content Groups."
2. To configure the selector expression, delimit the entire rule in quotes, and delimit string values within the rule in escaped quotes.

   The following is an example:

   "http.req.url.contains(\"jpg\")"
3. You cannot add Boolean values, insert &&, | |, or ! operators. Enter each expression element delimited in quotes. Multiple expressions in the definition are treated as a compound expression joined by logical ANDs.

   The following are examples:

   "http.req.url.query.value(\"ProductId\")" "http.req.url.query.value(\"BatchNum\")" "http.req.url.query.value(\"depotLocation\")"

To configure a policy or selector expression by using the configuration utility

1. Start the policy or selector definition as described in "To configure a policy for caching or invalidation by using the configuration utility" or "To configure a selector by using the configuration utility."
2. In the Expression field, you can either manually type the default syntax by clicking Switch to Classic Syntax or create new expression using Expression Editor.
3. To insert an operator between two parts of a compound expression, click the Operators button and select the operator type. The following is an example of a configured expression with a Boolean OR (signaled by double vertical bars, | |):

4. Click Frequently Used Expressions drop-down to insert the commonly used expressions.
5. To test the expression, click the Evaluate. In the Expression Evaluator dialog box, select the Flow Type that matches the expression. In the data field, paste the HTTP request or response that you hope to parse using the expression, and click Evaluate.

Displaying Cached Objects and Cache Statistics

Sep 08, 2016

You can view particular cached objects, and you can view summary statistics on cache hits, misses, and memory usage. The statistics provide insight on the amount of data that is being served from the cache, what items are responsible for the largest performance benefit, and what you can tune to improve cache performance.

This section includes the following details:

- Viewing Cached Objects
- Finding Particular Cached Responses
- Viewing Cache Statistics

Updated: 2014-08-04

After enabling caching, you can view details for cached objects. For example, you can view the following items:

- Response sizes and header sizes
- Status codes
- Content groups
- ETag, Last-Modified, and Cache-Control headers
- Request URLs
- Hit parameters
- Destination IP addresses
- Request and response times

To view a list of cached objects by using the command line interface

At the command prompt, type:

show cache object

Table 1. Properties of Cached Objects

Properties	Specifies
Response size (bytes)	The size of the response header and body.
Response header size (bytes)	The size of the header portion of the response.
Response status code	The status code sent with the response.

Properties	Specifies
ETag	The ETag header inserted in the response. Typically, this header indicates whether the response has changed recently.
Last-Modified	The Last-Modified header inserted in the response. This header indicates the date that the response was last changed.
Cache-Control	The Cache-Control header inserted in the response.
Date	The Date header that indicates when the response was sent.
Contentgroup	The content group where the response is stored.
Complex match	If this object was cached on the basis of parameterized values, this field value is YES.
Host	The host specified in the URL that requested this response.
Host port	The listen port for the host specified in the URL that requested this response.
URL	The URL issued for the stored response.
Destination IP	The IP address of the server from which this response was fetched.
Destination port	The listen port for the destination server.
Hit parameters	If the content group that stores the response uses hit parameters, they are listed in this field.
Hit selector	If this content group uses a hit selector, it is listed in this field.
Inval selector	If this content group uses an invalidation selector, it is listed in this field.
Selector Expressions	If this content group uses a selector, this field displays the expression that defines the selection rule.
Request time	The time in milliseconds since the request was issued.

Response time	Specifies in milliseconds since the cache started to receive the response.
Age	Amount of time the object has been in the cache.
Expiry	Amount of time after which the object is marked as expired.
Flushed	Whether the response has been flushed after expiry.
Prefetch	If Prefetch has been configured for this content group, the amount of time before expiry during which the object is fetched from the origin. Prefetch does not apply to negative objects (for example, 404 "object not found" responses).
Current readers	Approximately the current number of hits being served. When a response with a Content-Length header object is being downloaded, the current misses and the current readers values are each typically 1. When a chunked response object is being downloaded, the current misses value is typically 1, but the current readers value is typically 0, because the chunked response that is served to the client does not come from the integrated caching buffers.
Current misses	The current number of requests that resulted in a cache miss and fetching from the origin server. This value is typically 0 or 1. If Poll Every Time is enabled for a content group, the count can be greater than 1.
Hits	The number of cache hits for this object.
Misses	The number of cache misses for this object.
Compression format	The type of compression applied to this object. Compression formats include gzip, deflate, compress, and pack200-gzip.
HTTP version in response	The version of HTTP that was used to send the response.
Weak etag present in response	Strong etag headers change if the bits of an entity change. Strong headers are based on the octet values of an object. Weak etag headers change if the meaning of an entity changes. Weak etag values are based on semantic identity. Weak etags values start with a "W."
Negative marker cell	A marker object is cacheable, but it does not yet meet all the criteria for being cached. For example, the object may exceed the maximum response size for the content group. A marker cell is created for objects of this type. The next time a user sends a request for this object, a cache miss is served.

Properties	Specifies
Reason marker created	The reason a marker cell was created (for example, “Waiting for minhit,” “Content-length response data is not in group size limit”).
Auto poll every time	If the integrated cache receives an already expired 200 OK response with validators (either the Last-Modified or the ETag response headers) it stores the response and marks it as Auto-PET (automatically poll every time).
NetScaler Etag inserted in response	A variation of the ETag header generated by the NetScaler appliance. A value of YES appears if the NetScaler inserts an Etag in the response.
Full response present in cache	Indicates whether this is a complete response.
Destination IP verified by DNS	Indicates whether DNS resolution was performed when storing the object.
Object stored through a cache forward proxy	Indicates whether this response was stored due to a forward proxy that is configured in the integrated cache.
Object is a Delta basefile	A response that is delta-compressed.
Waiting for minhits	Indicates whether this content group requires a minimum number of origin server hits before caching a response.
Minhit count	If this content group requires a minimum number of origin server hits before caching an object, this field displays a count of the number of hits received so far.
HTTP Request Method	The method, GET or POST, used in the request that obtained this object.
Stored by policy	The name of the caching policy that caused this object to be stored. A value of NOT AVAILABLE indicates that the policy has been deactivated or deleted. A value of NONE indicates that the object did not match a visible policy, but was stored according to internal criteria for caching.

Properties	Specifies
Application firewall metadata exists	This parameter is used when the application firewall and the integrated cache are both enabled. The application firewall analyzes the contents of a response page, stores its metadata (for example, URLs and forms contained in page), and exports the metadata with the response to the cache. The cache stores the page and the metadata, and when the cache serves the page, it sends the metadata back to the request's session.
HTTP callout object, name, type, response	These cells indicate whether this data was stored as a result of an HTTP Callout expression, and provide information about various aspects of the callout and the corresponding response. For more information about HTTP callouts, see "HTTP Callouts".

To view cached objects by using the configuration utility

Navigate to Optimization > Integrated Caching > Cache Objects. You can view all the cached objects and sort them accordingly as per your requirement.

Updated: 2014-08-08

You can find individual items in the cache based on search criteria. There are different methods for finding cached items, depending on whether the content group that contains the data uses hit and invalidation selectors, as follows:

- If the content group uses selectors, you can only conduct the search using the Locator ID for the cached item.
- If the content group does not use selectors, you conduct the search using criteria such as URL, host, content group name, and so on.

When searching for a cached response, you can locate some items by URL and host. If the response is in a content group that uses a selector, you can find it only by using a Locator number (for example, 0x00000000ad7af00000050). To save a Locator number for later use, right-click the entry and select **Copy**. For more information about selectors, see "Configuring Selectors and Basic Content Groups."

To display cached responses in content groups that do not have a selector by using the command line interface

At the command prompt, type:

show cache object [-locator <positiveInteger>] | [(-url <URL> (-host <hostName> [-port <port>] [-groupName <contentGroupName>] [-httpMethod GET | POST])) | [-httpStatus<positive integer>] | -group <contentGroupName> | -ignoreMarkerObjects (ON | OFF) | -includeNotReadyObjects (ON | OFF)]

To display cached responses in content groups that have a selector by using the command line interface

At the command prompt, type:

show cache object -locator <locatorString> MarkerObjects (ON | OFF) | -includeNotReadyObjects (ON | OFF) | [-httpStatus<positive integer>]

To display cached responses in content groups that do not have a selector by using the configuration utility

Navigate to Optimization > Integrated Caching > Cache Objects, click Search, and set the search criteria to view the required cached response.
If you have not yet configured any content groups, all of the objects are in the Default group.

To display cached responses in content groups that have a selector by using the configuration utility

Navigate to Optimization > Integrated Caching > Cache Objects, click Search, and set the selector search criteria to view the required cached response.

Updated: 2013-10-28

The following table summarizes the detailed cache statistics that you can view.

Table 2. Integrated Cache Statistics

Counter	Specifies
Hits	Responses that are found in and served from the integrated cache. Includes static objects such as image files, pages with status codes 200, 203, 300, 301, 302, 304, 307, 403, 404, 410, and responses that match a user-defined policy with a CACHE action..
Misses	Intercepted HTTP requests where the response was ultimately fetched from origin server.
Requests	Total cache hits plus total cache misses.
Non-304 hits	If the user requests an item more than once, and the item in the cache is unchanged since the last time the NetScaler appliance served it, the NetScaler appliance serves a 304 response instead of the cached object. This statistic indicates how many items the NetScaler appliance served from the cache, excluding 304 responses.
304 hits	Number of 304 (object not modified) responses the NetScaler appliance served from the cache.
304 hit ratio (%)	Percentage of 304 responses that the NetScaler appliance served, relative to other responses.
Hit ratio (%)	Percentage of responses that the NetScaler appliance served from the cache (cache hits) relative to responses that could not be served from the cache.

Counter	Specifies
Origin bandwidth saved (%)	An estimate of the processing capacity that the NetScaler appliance saved on the origin server due to serving responses from the cache.
Bytes served by the NetScaler	Total number of bytes that the NetScaler appliance served from the origin server and the cache.
Bytes served by cache	Total number of bytes that the NetScaler appliance served from the cache.
Byte hit ratio(%)	Percentage of data that the NetScaler appliance served from the cache, relative to all of the data in all served responses.
Compressed bytes from cache	Amount of data, in bytes, that the NetScaler appliance served in compressed form.
Storable misses	If the NetScaler appliance does not find a requested object in the cache, it fetches the object from the origin server. This is known as a cache miss. A storable cache miss can be stored in the cache.
Non-storable misses	A non-storable cache miss cannot be stored in the cache.
Misses	All cache misses.
Revalidations	Max-Age setting in a Cache-Control header determines, in number of seconds, when an intervening cache must revalidate the content with the integrated cache before serving it to the user. For more information, see "Inserting a Cache-Control Header."
Successful revalidations	Number of re-validations that have been performed. For more information, see "Inserting a Cache-Control Header."
Conversions to conditional req	A user-agent request for a cached PET object is always converted to a conditional request and sent to the origin server. For more information, see "Polling the Origin Server Every Time a Request Is Received."
Storable miss ratio (%)	Storable cache misses as a percentage of non-storable cache misses.

Counter	Specifies
Successful reval ratio (%)	Successful revalidations as a percentage of all revalidation attempts. For more information, see "Inserting a Cache-Control Header."
Expire at last byte	Number of times that the cache expired content immediately after receiving the last body byte. Only applicable to positive responses, as described in the table "Cache Hits and Misses." For more information, see "Example of Performance Optimization."
Flashcache misses	If you enable Flash Cache, the cache allows only one request to reach the server, eliminating flash crowds. This statistic indicates the number of Flash Cache requests that were cache misses. For more information, "Queuing Requests to the Cache."
Flashcache hits	Number of Flash Cache requests that were cache hits. For more information, see "Queuing Requests to the Cache."
Parameterized inval requests	Requests that match a policy with an invalidation (INVAL) action and a content group that uses an invalidation selector or parameters to selectively expire cached objects in the group.
Full inval requests	Requests that match an invalidation policy where the invalGroups parameter is configured and expires one or more content groups.
Inval requests	Requests that match an invalidation policy and result in expiration of specific cached responses or entire content groups.
Parameterized requests	Number of cache requests that were processed using a policy with a parameterized content group.
Parameterized non-304 hits	Number of cache requests that were processed using a policy with a parameterized content group, where full cached response was found, and the response was not a 304 (object not updated) response.
Parameterized 304 hits	Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found, and the object was a 304 (object not updated) response.
Total parameterized hits	Number of cache requests that were processed using a policy with a parameterized content group, where the cached object was found.
Parameterized	Percentage of 304 (object not updated) responses that were found using a parameterized policy,

Counter	Specifies
304 hit ratio (%)	relative to all cache hits.
Poll every time requests	If Poll Every Time is enabled, the NetScaler appliance always consults the origin server before serving a stored object. For more information, see "Polling the Origin Server Every Time a Request Is Received."
Poll every time hits	Number of times a cache hit was found using the Poll Every Time method. For more information, see "Polling the Origin Server Every Time a Request Is Received."
Poll every time hit ratio (%)	Percentage of cache hits using the Poll Every Time method, relative to all searches for cached objects using Poll Every Time. For more information, see "Polling the Origin Server Every Time a Request Is Received."
Maximum memory (KB)	Maximum amount of memory in the NetScaler appliance that is allocated to the cache. For more information, see "Configuring Global Attributes for Caching."
Maximum memory active value (KB)	Maximum amount of memory (active value) that will be set after the memory is actually allocated to the cache. For more information, see "How to Configure the Integrated Caching Feature of a NetScaler Appliance for various Scenarios."
Utilized memory (KB)	Amount of memory that is actually being used.
Memory allocation failures	Number of failed attempts to utilize memory for the purpose of storing a response in the cache.
Largest response so far	Largest response in bytes found in either the cache or the origin server and sent to the client.
Cached objects	Number of objects in the cache, including responses that have not yet been fully downloaded and responses that have been expired but not yet flushed.
Marker objects	Marker objects are created when a response exceeds the maximum or minimum response size for the content group, or has not yet received the minimum number of hits for the content group.
Hits being	Number of hits that have been served from the cache.

Counter	Specifies
served	
Misses being handled	Responses that were fetched from the origin server, stored in the cache, and then served. Should approximate the number for storable misses. Does not include non-storable misses.

To view summary cache statistics by using the command line interface

At the command prompt, type:

stat cache

To view specific cache statistics by using the command line interface

At the command prompt, type:

stat cache -detail [-fullValues] [-ntimes <positiveInteger>] [-logFile <inputFilename>]

To view summary cache statistics by using the configuration utility

1. Click the Dashboard tab at the top of the page.
2. Scroll down to the Integrated Caching section of the window.
3. To see detailed statistics, click the More... link at the bottom of the table.

To view specific cache statistics by using the configuration utility

1. Click the Reporting tab at the top of the page.
2. Under Built-In Reports, expand Integrated Cache, and then click the report with the statistics you want to view.
3. To save the report as a template, click Save As and name the report. The saved report appears under Custom Reports.

Improving Cache Performance

May 19, 2015

You can improve the performance of integrated cache, including handling simultaneous requests for the same cached data, avoiding delays that are associated with refreshing cached responses from the origin server, and ensuring that a response is requested often enough to be worth caching.

This section includes the following details:

- Reducing Flash Crowds
- Caching a Response after a Client Halts a Download
- Requiring a Minimum Number of Server Hits before Caching
- Example of Performance Optimization

Updated: 2015-05-20

Flash crowds occur when many users simultaneously request the same data. All of the requests in a flash crowd can become cache misses if you configured the cache to serve hits only after the entire object is downloaded.

The following techniques can reduce or eliminate flash crowds:

- **PREFETCH**: Refreshes a positive response before it expires to ensure that it never becomes stale or inactive.
  For more information, see "Refreshing a Response Prior to Expiration" section.
- **Cache buffering**: Starts serving a response to multiple clients as soon as it receives the response header from the origin server, rather than waiting for the entire response to be downloaded.
  The only limit on the number of clients that can download a response simultaneously is the available system resources.

  The Citrix NetScaler appliance downloads and serves responses even if the client that initiated the download halts before the download is complete. If the size of the response exceeds the cache size or if the response is chunked, the cache stops storing the response, but service to the clients is not disrupted.
- **Flash Cache**: Flash Cache queues requests to the cache, and allows only one request to reach the server at a time.
  For more information, see "Queuing Requests to the Cache" section.

Refreshing a Response Before Expiration

To ensure that a cached response is fresh whenever it is needed, the PREFETCH option refreshes a response before its calculated expiration time. The prefetch interval is calculated after receiving the first client request. From that point onward, the NetScaler appliance refreshes the cached response at a time interval that you configure in the PREFETCH parameter.

This setting is useful for data that is updated frequently between requests. It does not apply to negative responses (for example, 404 messages).

At the command prompt, type:

set cache contentgroup <name> -prefetch YES [-prefetchPeriod <seconds> | -prefetchPeriodMilliSec <milliseconds>] [-

prefetchMaxPending <positiveInteger>]

1. Navigate to Optimization > Integrated Caching > Content Groups, and select the content group.
2. On Others tab, in the Flash Crowd and Prefetch group, select Prefetch option, and specify the values in Interval and Maximum number of pending prefetches text boxes.

Queuing Requests to the Cache

The Flash Cache option queues requests that arrive simultaneously (a flash crowd), retrieves the response, and distributes it to all the clients whose requests are in the queue. If, during this process, the response becomes non-cacheable, the NetScaler appliance stops serving the response from the cache and instead serves the origin server's response to the queued clients. If the response is not available, the clients receive an error message.

Flash Cache is disabled by default. You cannot enable Poll Every Time (PET) and Flash Cache on the same content group.

One disadvantage of Flash Cache is if the server replies with an error (for example, a 404 that is quickly remedied), the error is fanned out to the waiting clients.

Note: If Flash Cache is enabled, in some situations the NetScaler appliance is unable to correctly match the Accept-Encoding header in the client request with the Content-Encoding header in the response. The NetScaler appliance can assume that these headers match and mistakenly serve a hit. As a work-around, you can configure Integrated Caching policies to disallow serving hits to clients that do not have an appropriate Accept-Encoding header.

At the command prompt, type:

set cache contentgroup <contentGroupName> -flashcache yes

1. Navigate to Optimization > Integrated Caching > Content Groups, and select the content group.
2. On Others tab, in the Flash Crowd and Prefetch group, select Prefetch option.

Updated: 2014-08-08

You can set the Quick Abort parameter to continue caching a response, even if the client halts a request before the response is in the cache.

If the downloaded response size is less than or equal to the Quick Abort size, the NetScaler appliance stops downloading the response. If you set the Quick Abort parameter to 0, all downloads are halted.

To configure quick abort size by using the command line interface

At the command prompt, type:

set cache contentgroup <name> -quickAbortSize <integerInKBytes>

To configure quick abort size by using the configuration utility

1. Navigate to Optimization > Integrated Caching > Content Groups, and select the content group.
2. On Memory tab, set the relevant value in Quick Abort: Continue caching if more than text box.

Updated: 2015-05-19

You can configure the minimum number of times that a response must be found on the origin server before it can be cached. You should consider increasing the minimum hits if the cache memory fills up quickly and has a lower-than-expected hit ratio.

The default value for the minimum number of hits is 0. This value caches the response after the first request.

To configure the minimum number of hits that are required before caching by using the command line interface

At the command prompt, type:

set cache contentgroup <name> -minhits <positiveInteger>

To configure the minimum number of hits that are required before caching by using the configuration utility

1. Navigate to Optimization > Integrated Caching > Content Groups, and select the content group.
2. On Memory tab, set the relevant value in Do not cache, if hits are less than text box.

Updated: 2013-10-28

In this example, a client accesses a stock quote. Stock quotes are highly dynamic. You configure the integrated cache to serve the same stock quote to concurrent clients without sending multiple requests to the origin server. The stock quote expires after it is downloaded to all of the clients, and the next request for a quote for the same stock is fetched from the origin server. This ensures that the quote is always up to date.

The following task overview describes the steps to configure the cache for the stock quote application.

Task overview: Configuring caching for a stock quote application

1. Create a content group for stock quotes.
   For more information, see "About Content Groups."

   Configure the following for this content group:

   - On the Expiry Method tab, select the Expire after complete response received check box.
   - On the Others tab, select the Flash Cache check box, and click Create.
2. Add a cache policy to cache the stock quotes.
   For more information, see "Configuring a Policy in the Integrated Cache."

   Configure the following for the policy:

   - In the Action and Store in Group lists, select CACHE and select the group that you defined in the previous step.
   - Click Add, and in the Add Expression dialog box configure an expression that identifies stock quote requests, for example:
     http.req.url.contains("cgi-bin/stock-quote.pl")

3. Activate the policy.
   For more information, see "Globally Binding an Integrated Caching Policy." In this example, you bind this policy to request-time override processing and set the priority to a low value.

Configuring Cookies, Headers, and Polling

Feb 13, 2017

This section describes the procedures to configure how the cache manages cookies, HTTP headers, and origin server polling, including modifying default behavior that causes the cache to diverge from documented standards, overriding HTTP headers that might cause cacheable content to not be stored in the cache, and configuring the cache to always poll the origin for updated content under specialized circumstances.

For details, see the following sections:

- Divergence of Cache Behavior from the Standards
- Removing Cookies from a Response
- Inserting HTTP Headers at Response Time
- Ignoring Cache-Control and Pragma Headers in Requests
- Polling the Origin Server Every Time a Request Is Received
- PET and Client-Specific Content
- PET and Authentication, Authorization, and Auditing

Updated: 2013-10-28

By default, the integrated cache conforms to the following standards:

- RFC 2616, “Hypertext Transfer Protocol HTTP/1.1”
- The caching behaviors described in RFC 2617, “HTTP Authentication: Basic and Digest Access Authentication”
- The caching behavior described in RFC 2965, “HTTP State Management Mechanism”

The built-in policies and the Default content group attributes ensure conformance with most of these standards.

The default integrated cache behavior diverges from the specifications as follows:

- There is limited support for the Vary header.
  By default, any response containing a Vary header is considered to be non-cacheable unless it is compressed. A compressed response contains Content-Encoding: gzip, Content-Encoding: deflate, or Content-Encoding: pack200-gzip and is cacheable even if it contains the Vary: Accept-Encoding header.

- The integrated cache ignores the values of the headers Cache-Control: no-cache and Cache-Control: private.
  For example, a response that contains Cache-Control: no-cache=”Set-Cookie” is treated as if the response contained Cache-Control: no-cache. By default, the response is not cached.

- An image (Content-Type = image/*) is always considered cacheable even if an image response contains Set-Cookie or Set-Cookie2 headers, or if an image request contains a Cookie header.
  The integrated cache removes Set-Cookie and Set-Cookie2 headers from a response before caching it. This diverges from RFC 2965. You can configure RFC-compliant behavior as follows:

  ```
  add cache policy rfc_compliant_images_policy -rule "http.res.header.set-cookie2.exists || http.res.header.set-cookie.exists" -action NOCACHE
  bind cache global rfc_compliant_images_policy -priority 100 -type REQ_OVERRIDE
  ```

- The following Cache-Control headers in a request force an RFC-compliant cache to reload a cached response from the origin server:

  ```
  Cache-control: max-age=0
  Cache-control: no-cache
  ```

  To guard against Denial of Service attacks, this behavior is not the default. For more information, see "Inserting a Cache-Control Header" section.

- By default, the caching module considers a response to be cacheable unless a response header states otherwise.

To make this behavior RFC 2616 compliant, set -weakPosRelExpiry and -weakNegResExpiry to 0 for all content groups.

Updated: 2014-08-12

Cookies are often personalized for a user, and typically should not be cached. The Remove Response Cookies parameter removes Set-Cookie and Set-Cookie2 headers before caching a response. By default, the Remove Response Cookies option for a content group prevents caching of responses with Set-Cookie or Set-Cookie2 headers.

Note that when images are cached, the built-in behavior is to remove the Set-Cookie and Set-Cookie2 headers before caching, no matter how the content group is configured.

Note: Citrix recommends that you accept the default Remove Response Cookies for every content group that stores embedded responses, for example, images.

To configure Remove Response Cookies for a content group by using the command line interface

At the command prompt, type:

set cache contentgroup <name> -removeCookies YES

To configure Remove Response Cookies for a content group by using the configuration utility

1. Navigate to Optimization > Integrated Caching > Content Groups, and select the content group.
2. On Others tab, in the Settings group, select Remove response cookies option.

Updated: 2014-08-12

The integrated cache can insert HTTP headers in responses that result from cache hits. The Citrix® NetScaler® appliance does not alter headers in responses that result from cache misses.

The following table describes headers that you can insert in a response.

Table 1. Different HTTP Headers You Can Insert in a Response That Is Served from the Cache

Header	Specifies
Age	Provides the age of the response in seconds, calculated from the time the response was generated at the origin server. By default, the cache inserts an Age header for every response that is served from the cache.
Via	Lists protocols and recipients between the start and end points for a request or a response. The NetScaler appliance inserts a Via header in every response that it serves from the cache. The default value of the inserted header is “NS-CACHE-9.2:last octet of the NetScaler IP address.” For more information, see "Configuring Global Attributes for Caching."
ETag	The cache supports response validation using Last-Modified and ETag headers to determine if a response is stale. The cache inserts an ETag in a response only if it caches the response and the origin server has not inserted its own ETag header. The ETag value is an arbitrary unique number. The ETag value for a response changes if it is refreshed from the origin server, but it stays the same if the server sends a 304 (object not updated) response. Origin servers typically do not generate validators for dynamic content because dynamic content is considered non-cacheable.

Header	Specifies
	You can override this behavior. With ETag header insertion, the cache is permitted to not serve full responses. Instead, the user agent is required to cache the dynamic response sent by the integrated cache the first time. To force a user agent to cache a response, you configure the integrated cache to insert an ETag header and replace the origin-provided Cache-Control header.
Cache-Control	The NetScaler appliance typically does not modify cacheability headers in responses that is serves from the origin server. If the origin server sends a response that is labeled as non-cacheable, the client treats the response as non-cacheable even if the NetScaler appliance caches the response. To cache dynamic responses in a user agent, you can replace Cache-Control headers from the origin server. This applies only to user agents and other intervening caches. They do not affect the integrated cache. For more information, see "Inserting a Cache-Control Header" section.

Inserting an Age, Via, or ETag Header

The following procedures describe how to insert Age, Via, and ETag headers.

At the command prompt, type:

set cache contentgroup <name> -insertVia YES -insertAge YES -insertETag YES

1. Navigate to Optimization > Integrated Caching > Content Groups, and select the content group.
2. On Others tab, in the HTTP Header Insertions group, select the Via, Age, or ETag options, as appropriate.
   The values for the other header types are calculated automatically. Note that you configure the Via value in the main settings for the cache.

Inserting a Cache-Control Header

When the integrated cache replaces a Cache-Control header that the origin server inserted, it also replaces the Expires header. The new Expires header contains an expiration time in the past. This ensures that HTTP/1.0 clients and caches (that do not understand the Cache-Control header) do not cache the content.

At the command prompt, type:

set cache contentgroup <name> -cacheControl <value>

1. Navigate to Optimization > Integrated Caching > Content Groups, and
   1. Click Expiry Method tab, clear the heuristic and default expiry settings and set the relevant value in Expire content after text box.
   2. Click Others tab and type the header you want to insert in the Cache-Control text box. Alternatively, click Configure to set the Cache-Control directives in cached responses.

Updated: 2014-08-12

By default, the caching module processes Cache-Control and Pragma headers. The following tokens in Cache-Control headers are processed as described in RFC 2616.

- max-age
- max-stale
- only-if-cached
- no-cache

A Pragma: no-cache header in a request is treated in the same way as a Cache-Control: no-cache header.

If you configure the caching module to ignore Cache-Control and Pragma headers, a request that contains a Cache-Control: No-Cache header causes the NetScaler appliance to retrieve the response from the origin server, but the cached response is not updated. If the caching module processes Cache-Control and Pragma headers, the cached response is refreshed.

The following table summarizes the implications of various settings for these headers and the Ignore Browser's Reload Request setting.

Table 2. Outcome of Settings for Ignoring Reload Requests, Cache-Control, and Pragma Headers

Setting for Ignore Cache-Control and Pragma Headers	Setting for Ignore Browser's Reload Request	Outcome
Yes	Yes or No	Ignore the Cache-Control and Pragma headers from the client, including the Cache-Control: no-cache directive.
No	Yes	The Cache-Control: no-cache header produces a cache miss, but a response that is already in the cache is not refreshed.
No	No	A request that contains a Cache-Control: no-cache header causes a cache miss and the stored response is refreshed.

To ignore Cache-Control and Pragma headers in a request by using the command line interface

At the command prompt, type:

set cache contentgroup <name> -ignoreReqCachingHdrs YES

To ignore browser reload requests by using the command line interface

At the command prompt, type:

set cache contentgroup <name> -ignoreReloadReq NO
Note that by default, the -ignoreReloadReq parameter is set to YES.

To ignore Cache-Control and Pragma headers in a request by using the configuration utility

1. Navigate to Optimization > Integrated Caching > Content Groups, and select the content group.
2. On Others tab, in the Settings group, select Ignore Cache-control and Pragma Headers in Requests option.

Example of a Policy to Ignore Cache-Control Headers

In the following example, you configure a request-time override policy to cache responses that contain Content-type: image/* regardless of the Cache-Control header in the response.

1. Flush the cache using the Invalidate All option.

   For more information, see "Flushing Responses in a Content Group."

2. Configure a new cache policy, and direct the policy to a particular content group. For more information, see "Configuring a Policy in the Integrated Cache."
3. Ensure the content group that the policy uses is configured to ignore Cache-Control headers, as described in "Ignoring Cache-Control and

Pragma Headers in Requests."

4. Bind the policy to the request-time override policy bank.

   For more information, see "Globally Binding an Integrated Caching Policy."

Updated: 2014-08-12

You can configure the NetScaler appliance to always consult the origin server before serving a stored response. This is known as Poll Every Time (PET). When the NetScaler appliance consults the origin server and the PET response has not expired, a full response from the origin server does not overwrite cached content. This property is useful when serving client-specific content.

After a PET response expires, the NetScaler appliance refreshes it when the first full response arrives from the origin server.

The Poll Every Time (PET) function works as follows:

- For a cached response that has validators in the form of an ETag or a Last-Modified header, if the response expires it is automatically marked PET and cached.
- You can configure PET for a content group.
  If you configure a content group as PET, every response in the content group is marked PET. The PET content group can store responses that do not have validators. Responses that are automatically marked PET are always expired. Responses that belong to a PET content group can expire after a delay, based on how you configure the content group.

Two types of requests are affected by polling:

- **Conditional Requests**: A client issues a conditional request to ensure that the response that it has is the most recent copy.
  A user-agent request for a cached PET response is always converted to a conditional request and sent to the origin server. A conditional request has validators in If-Modified-Since or If-None-Match headers. The If-Modified-Since header contains the time from the Last-Modified header. An If-None-Match header contains the response's ETag header value.

  If the client's copy of the response is fresh, the origin server replies with 304 Not Modified. If the copy is stale, a conditional response generates a 200 OK that contains the entire response.

- **Non-Conditional Requests**: A non-conditional request can only generate a 200 OK that contains the entire response.

The following table summarizes response types based on the origin server's response

Table 3. How Responses Are Affected by Poll Every Time

Origin Server Response	Action
Send the full response	The origin server sends the response as-is to the client. If the cached response has expired, it is refreshed.
304 Not Modified	The following header values in the 304 response are merged with the cached response and the cached response is served to the client: • Date • Expires • Age • Cache-Control header Max-Age and S-Maxage tokens
401 Unauthorized 400 Bad Request	The origin's response is served as-is to the client. The cached response is not changed.

Origin Server Response	Action
405 Method Not Allowed 406 Not Acceptable	
407 Proxy Authentication Required	
Any other error response, for example, 404 Not Found	The origin's response is served as-is to the client. The cached response is removed.

Note: The Poll Every Time parameter treats the affected responses as non-storable.

To configure poll every time by using the command line interface

At the command prompt, type:

add cache contentgroup <contentGroupName> -pollEveryTime YES

To configure poll every time by using the configuration utility

1. Navigate to Optimization > Integrated Caching > Content Groups, and select the content group.
2. On Others tab, in the Settings group, select Poll every time (validate cached content with origin for every request) option.

PET and Client-Specific Content

The PET function can ensure that content is customized for a client. For example, a Web site that serves content in multiple languages examines the Accept-Language request header to select the language for the content that it is serving. For a multi-language Web site where English is the predominant language, all English language content can be cached in a PET content group. This ensures that every request goes to the origin server to determine the language for the response. If the response is English, and the content has not changed, the origin server can serve a 304 Not Modified to the cache.

The following example shows commands to cache English responses in a PET content group, configure a named expression that identifies English responses in the cache, and configure a policy that uses this content group and named expression. Bold is used for emphasis:

```
add cache contentgroup EnglishLanguageGroup -pollEveryTime YES
add expression containsENExpression –rule "http.res.header(\"Content-Language\").contains(\"en\")"
add cache policy englishPolicy -rule containsENExpression -action CACHE -storeInGroup englishLanguageGroup
bind cache policy englishPolicy -priority 100 -precedeDefRules NO
```

PET and Authentication, Authorization, and Auditing

Outlook Web Access (OWA) is a good example of dynamically generated content that benefits from PET. All mail responses (*.EML objects) have an ETag validator that enables them to be stored as PET responses.

Every request for a mail response travels to the origin server, even if the response is cached. The origin server determines whether the requestor is authenticated and authorized. It also verifies that the response exists in the origin server. If all results are positive, the origin server sends a 304 Not Modified response.

Configuring the Integrated Cache as a Forward Proxy

Aug 08, 2014

The integrated cache can service as a forward proxy device that passes requests to other NetScaler appliances or to other types of cache servers. You configure the integrated cache as a forward proxy by identifying the IP addresses of the cache server or servers. After configuring the forward proxy, the NetScaler appliance sends requests that contain the configured IP address on to the cache server instead of involving the integrated cache.

At the command prompt, type:

add cache forwardProxy <IPAddress> <port>

1. Navigate to Optimization > Integrated Caching > Forward Proxy, and add a forward proxy by specifying the IP address and port number.

Default Settings for the Integrated Cache

Aug 26, 2013

The Citrix NetScaler integrated cache feature provides built-in policies with default settings as well as initial settings for the Default content group. The information in this section defines the parameters for the built-in policies and Default content group.

Updated: 2013-08-26

The integrated cache has built-in policies. The NetScaler appliance evaluates the policies in a particular order, as discussed in the following sections.

You can override these built-in policies with a user-defined policy that is bound to a request-time override or response-time override policy bank.

Note that if you configured policies prior to release 9.0 and specified the -precedeDefRules parameter when binding the policies, they are automatically assigned to override-time bind points during migration.

Viewing the Default Policies

The built-in policy names start with an underscore (_). You can view the built-in policies from the command line and the administrative console using the show cache policy command.

Default Request Policies

You can override the following built-in request time policies by configuring new policies and binding them to the request-time override processing point. In the following policies, note that the MAY_NOCACHE action stipulates that the transaction is cached only when there is a user-configured or built-in CACHE directive at response time.

The following policies are bound to the _reqBuiltinDefaults policy label. They are listed in priority order.

1. Do not cache a response for a request that uses any method other than GET.
   The policy name is **_nonGetReq**. The following is the policy rule:

   !HTTP.REQ.METHOD.eq(GET)

2. Set a NOCACHE action for a request with header value that contains If-Match or If-Unmodified-Since.
   The policy name is **_advancedConditionalReq**. The following is the policy rule:

   HTTP.REQ.HEADER("If-Match").EXISTS || HTTP.REQ.HEADER("If-Unmodified-Since").EXISTS

3. Set a MAY_NOCACHE action for a request with the following header values: Cookie, Authorization, Proxy-authorization or a request which contains the NTLM or Negotiate header.
   The policy name is **_personalizedReq**. The following is the policy rule:

   HTTP.REQ.HEADER("Cookie").EXISTS || HTTP.REQ.HEADER("Authorization").EXISTS || HTTP.REQ.HEADER("Proxy-Authorization").EXISTS || HTTP.REQ.IS_NTLM_OR_NEGOTIATE

Default Response Policies

You can override the following default response-time policies by configuring new policies and binding them to the response-time override processing point.

The following policies are bound to the **_resBuiltinDefaults** policy label and are evaluated in the order in which they are listed:

1. Do not cache HTTP responses unless they are of type 200, 304, 307, 203 or if the types are between 400 and 499 or between 300 and 302.
   The policy name is **_uncacheableStatusRes**. The following is the policy rule:

   !((HTTP.RES.STATUS.EQ(200)) || (HTTP.RES.STATUS.EQ(304)) || (HTTP.RES.STATUS.BETWEEN(400,499)) || (HTTP.RES.STATUS.BETWEEN(300, 302)) || (HTTP.RES.STATUS.EQ(307))|| (HTTP.RES.STATUS.EQ(203)))

2. Do not cache an HTTP response if it has a Vary header with a value of anything other than Accept-Encoding.
   The compression module inserts the Vary: Accept_Encoding header. The name of this expression is **_uncacheableVaryRes**. The following is the policy rule:

   ((HTTP.RES.HEADER("Vary").EXISTS) && ((HTTP.RES.HEADER("Vary").INSTANCE(1).LENGTH > 0) || (!HTTP.RES.HEADER("Vary").STRIP_END_WS.SET_TEXT_MODE(IGNORECASE).eq("Accept-Encoding"))))

3. Do not cache a response if its Cache-Control header value is No-Cache, No-Store, or Private, or if the Cache-Control header is not valid.
   The policy name is **_uncacheableCacheControlRes**. The following is the policy rule:

   ((HTTP.RES.CACHE_CONTROL.IS_PRIVATE) || (HTTP.RES.CACHE_CONTROL.IS_NO_CACHE) || (HTTP.RES.CACHE_CONTROL.IS_NO_STORE) || (HTTP.RES.CACHE_CONTROL.IS_INVALID))

4. Cache responses if the Cache-Control header has one of the following values: Public, Must-Revalidate, Proxy-Revalidate, Max-Age, S-Maxage.
   The policy name is **_cacheableCacheControlRes**. The following is the policy rule:

   ((HTTP.RES.CACHE_CONTROL.IS_PUBLIC) || (HTTP.RES.CACHE_CONTROL.IS_MAX_AGE) || (HTTP.RES.CACHE_CONTROL.IS_MUST_REVALIDATE) || (HTTP.RES.CACHE_CONTROL.IS_PROXY_REVALIDATE) || (HTTP.RES.CACHE_CONTROL.IS_S_MAXAGE))

5. Do not cache responses that contain a Pragma header.
   The name of the policy is **_uncacheablePragmaRes**. The following is the policy rule:

   HTTP.RES.HEADER("Pragma").EXISTS

6. Cache responses that contain an Expires header.
   The name of the policy is **_cacheableExpiryRes**. The following is the policy rule:

   HTTP.RES.HEADER("Expires").EXISTS

7. If the response contains a Content-Type header with a value of Image, remove any cookies in the header and cache it.
   The name of the policy is **_imageRes**. The following is the policy rule:

   HTTP.RES.HEADER("Content-Type").SET_TEXT_MODE(IGNORECASE).STARTSWITH("image/")

   You could configure the following content group to work with this policy:

```
add cache contentgroup nocookie_group -removeCookies YES
```

8. Do not cache a response that contains a Set-Cookie header.
   The name of the policy is **_ personalizedRes**. The following is the policy rule:

   ```
   HTTP.RES.HEADER("Set-Cookie").EXISTS || HTTP.RES.HEADER("Set-Cookie2").EXISTS
   ```

Restrictions on Default Policies

You cannot override the following built-in request time policies with user-defined policies.

These policies are listed in priority order.

1. Do not cache any responses if the corresponding HTTP request lacks a GET or POST method.
2. Do not cache any responses for a request if the HTTP request URL length plus host name exceeds 1744 byes.
3. Do not cache a response for a request that contains an If-Match header.
4. Do not cache a request that contains an If-Unmodified-Since header.
   Note that this is different from the If-Modified-Since header.
5. Do not cache a response if the server does not set an expiry header.

You cannot override the following built-in response time policies. These policies are evaluated in the order in which they are listed:

1. Do not cache responses that have an HTTP response status code of 201, 202, 204, 205, or 206.
2. Do not cache responses that have an HTTP response status code of 4xx, with the exceptions of status codes 403, 404, and 410.
3. Do not cache responses if the response type is FIN terminated, or the response does not have one of the following attributes: Content-Length, or Transfer-Encoding: Chunked.
4. Do not cache the response if the caching module cannot parse its Cache-Control header.

When you first enable integrated caching, the NetScaler appliance provides one predefined content group named the Default content group. The following table shows the settings for this group.

Table 1. Predefined Settings for the Default Content Group

Parameter	Description	Default Value
Hit parameters	The hit parameters contain the parameter names that are significant for generating a response. In parameterized hit selection, NetScaler appliance matches the URL stem byte-for-byte, matches normalized values of the hit parameters, and matches the target service information.	none
Invalidation Parameters	These parameters mark a cached object as obsolete during parameterized selection. Specific objects, or all objects in a content group, are selected if the values of the	none

Parameter	Description	Default Value
	invalidation parameters in the object and in the request are same after normalization. The invalidation parameters are a subset of the hit parameters.	
Poll Every Time	Poll every time for the objects in this content group.	NO
Ignore reload request	Specifies whether a request can force the system to reload a cached object from the origin. To guard against Denial of Service attacks, you must set this flag to YES. To get RFC-compliant behavior you should set it to NO.	YES
Remove Response Cookies	If this option is disabled for a content group, and if the response contains cookies, the cookies are stored and served with every cache hit. By default, the remove cookies option is enabled for a content group, to prevent the integrated cache from storing any responses with Set-Cookie or Set-Cookie2 headers unless the response is an image.	YES
Prefetch	The Prefetch option refreshes an object when it is about to expire. This ensures that the object remains stale or inactive (and therefore it cannot be served) for a shorter duration of time.	YES
Prefetch period	This duration in seconds during which prefetch should be attempted, immediately before the object's calculated expiry time.	heuristic
Maximum outstanding prefetches	The number of items that can be subjected to a prefetch at a time.	4294967295
Flashcache	Determines whether to enable queuing of client requests and simultaneous distribution of responses to all clients in the queue.	NO
Expire at last byte	Determines whether to expire a cached response immediately after serving it.	NO
Insert Via header	Defines a string to be inserted in a Via header. By default, a Via header is inserted in all responses served from a content group. The Via header is not inserted for responses that are served by the origin server.	YES
Insert Age header	The Age header contains information about the age of the object in seconds as calculated by the integrated cache.	YES
Insert ETag header	With ETag header insertion, the integrated cache does not serve full responses on repeat requests. This is done by forcing the user agent to cache the dynamic response	YES

Parameter	Description	Default Value
	sent by the cache the first time.	
Cache-control header	You can enable caching of dynamic objects in the user agent by replacing the Cache-Control headers that are inserted by the origin server. You must configure the new Cache-Control header to be inserted in the content group.	NONE
Quick abort size	If the size of an object that is being downloaded is less than or equal to the quick abort value, and a client aborts during the download, the cache stops downloading the response. If the object is larger than the quick abort size, the cache continues to download the response.	4194303 KBytes (maximum)
Minimum Response Size	You can control memory use by setting a minimum response size. Cached objects must be larger than the minimum response size.	0 KBytes
Maximum Response Size	You can control memory use by setting a maximum response size. Cached objects must be smaller than the maximum response size.	80 KBytes
Memory usage limit	Sets the maximum amount of memory that the cache can use. The effective limit is based on the available memory of the NetScaler appliance. The minimum value is 0 and the maximum value is unlimited.	UNLIMITED
Ignore caching headers in request	Disregards Cache-Control and Pragma headers in HTTP requests.	YES
MinHits configured	Number of hits that are required to qualify a response for storage in this content group.	0
Always evaluate policies		NO
Pinned	By default, when the cache is full the NetScaler appliance replaces the least recently used response first. The NetScaler appliance does not apply this behavior to content groups that are marked as pinned.	NO
Lazy DNS resolution	If set to YES, DNS resolution is performed for responses only if the destination IP address in the request does not match the destination IP address of the cached response.	YES

Troubleshooting

Jul 22, 2013

If the integrated cache feature does not work as expected after you have configured it, you can use some common tools to access NetScaler resources and diagnose the problem.

Updated: 2013-07-22

For best results, use the following resources to troubleshoot an integrated cache issue on a NetScaler appliance:

- The relevant trace files
- The ns.conf file
- The RFC 2616 document
- A copy of the object, if possible

In addition to the above resources, the following tools expedite troubleshooting:

- The iehttpheaders or a similar utility
- The Wireshark application customized for the NetScaler trace files

Updated: 2013-08-02

The following are effective steps to troubleshoot the objects that are not cached:

1. **Verify that the Integrated Caching feature is enabled.**
   Run the following command to verify the feature is enabled:

   ```
   show ns feature
   ```

   Following is sample output of the above command:

   ```
   show ns feature
       Feature status:
                   Web Logging: OFF
             Surge Protection: OFF
               Load Balancing: ON
           Content Switching: ON
           Cache Redirection: OFF
                 Sure Connect: OFF
          Compression Control: OFF
            Priority Queuing: OFF
               SSL Offloading: OFF
    Global Server Load Balancing: OFF
          Http DoS Protection: OFF
            Dynamic Routing: OFF
          Content Filtering: OFF
          Integrated Caching: ON
                    SSL VPN: OFF
   ```

OSPF Routing: OFF
RIP Routing: OFF
BGP Routing: OFF
Done

The entry highlighted in boldface (for reference) in the above output indicates that the integrated caching feature is enabled. If the feature is not enabled, run the following command to enable it:

enable ns feature IC

2. Make sure that sufficient memory is available on the NetScaler appliance.

Depending on the size of the object to be cached, memory available to store the cacheable object might be insufficient. You can set the memory limit for the integrated cache either globally or for individual content groups.

Run the following command to verify the memory allocated to integrated cache globally:

show cache parameter

Following is sample output of the above command:

show cache parameter
Integrated cache global configuration:
Memory usage limit: 256 MBytes
Via header: NS-CACHE-6.1: 101
Verify cached object using: HOSTNAME_AND_IP
Max POST body size to accumulate: 32768
Current outstanding prefetches: 0
Max outstanding prefetches: 4294967294
Treat NOCACHE policies as BYPASS policies: YES
Done

The entry highlighted in boldface (for reference) in the preceding output indicates the amount of memory allocated to the integrated cache globally.

Run the following command to verify the memory allocated to an individual content group:

show cache contentGroup <Content_Group_Name>

Following is sample output of the above command:

show cache contentgroup content1
Name: content1
Heuristic expiry time parameter: 10 percent
Weak relative expiry time - Positive responses: 3600 secs
Weak relative expiry time - Negative responses: 600 secs
Hit parameters: NONE
Invalidation Parameters: NONE
Invalidation restricted to host: NO
Ignore parameter value case: NO
Match Request Cookies: NO
Poll Every Time: NO
Ignore reload request: YES

Remove Response Cookies: YES
Prefetch: YES
Prefetch period: heuristic
Current outstanding prefetches: 0
Max outstanding prefetches: 4294967294
Flashcache: NO
Expire at last byte: NO
Insert Via header: YES
Insert Age header: YES
Insert ETag header: YES
Cache-control header: NONE
Quick abort size: 4194303 KBytes (MAXIMUM)
Minimum Response Size: 0 KBytes
Maximum Response Size: 80 KBytes
Memory usage: 0 Bytes
Memory usage limit: 64 MBytes
Ignore caching headers in request: YES
Non-304 hits: 0
304 hits: 0
Cached objects: 0
Number of times expired/flushed: 1
MinHits configured: 0
Always evaluate policies: NO
Pinned: NO

Done

The entry highlighted in boldface (for reference) in the above output indicates the amount of memory allocated to the content group.

3. **Verify that cacheable object is small enough to be stored within the configured memory limits.**
   Complete the following procedure to make space for the object to be cached:
   - Run the following command to flush the cache for the content group to which the object belongs:
     flush cache contentGroup <Content_Group_Name>
   - Verify that the object is cached. If the object is cached successfully, increase the memory allocated for the content group. Otherwise, run the following command to flush the cache globally:
     flush cache contentGroup ALL
   - Verify that the object is cached. If the object is cached successfully, consider increasing the global memory limit. If the object is still not cached, something else is causing the failure to cache the object.

   The memory allocated to the integrated cache depends on the NetScaler appliance model. You can allocate approximately half the available memory to the integrated cache. Similarly, the maximum about to memory you can allocate for a content group cannot be more than the memory allocated for global cache.

   To increase the global memory limit for the integrated cache, run the following command:

   set cache parameter -memLimit <Integer>

   To increase the memory limit for a content group, run the following command:

set cache contentgroup <contentgroup name> -memLimit <Integer>

4. **Verify that the cache policy is bound to an appropriate bind point, an appropriate priority is set for the policy, and an appropriateprecededefRulesswitch is configured.**
   You must activate a caching policy by binding it globally. To verify that the policy is active, run the following command:

   show cache global

   Following is sample output of the above command:

   show cache global
   1) Name: red_pol State: ACTIVE Priority: 1
      Rule: URL CONTAINS red
      Action: NOCACHE
      Precede default HTTP rules: YES
      Hits : 10
   Done

   In the output, verify the following settings:
   - **The policy is bound**: The output should contain all the active cache policies. If the cache policy for the object to be cached is not listed in the output, the policy is not yet bound. Run the following command to bind the policy globally:
     bind cache global <Policy_Name> -priority <Integer> [-precedeDefRules YES|NO]
   - **The policy is Active**: If the policy is bound, verify that the state of the policy is displayed as Active. The entry indicating that the policy in the preceding output is active is the first highlighted entry in the sample output of the show cache global command, above. The policy is active if it is bound globally and an appropriate priority is set. Otherwise, the status of the policy is showed as Passive.
   - **An appropriate priority is assigned to the policy**: The first highlighted entry in the sample output above displays the priority of the policy. If the priority is not set, you can use the bind command to set the priority of the policy. Note that the higher the priority number, the lower the priority. The priority assigned to the policy enables the NetScaler appliance to determine the order in which the policy should be evaluated.
     If evaluation of a particular policy fails, increase the priority of the policy so that it is evaluated before other policies. Caching policies, due to their high granularity, can be very complicated to configure. Therefore, two policies might be contradictory. As a result, only the higher-priority policy takes effect.
   - **The precedeDefRules switch** setting is correct: The second highlighted entry in the sample output of the show cache global command, above, indicates the precedeDefRules switch setting. This setting enables the NetScaler appliance to determine whether the policy should be evaluated before the default built-in policies, which implement the standard HTTP caching behavior, such as basing caching decisions on HTTP header fields (for example, the If-Modified-Since and no-cache fields). You can set this switch when binding the policy.
     For certain types of HTTP(S) transactions, you might have to make sure that the policy precedes default HTTP rules, to force objects to be cached. Especially if requests include header fields, such as If-Modified-Since, or responses contain the No-Cache header field, you might have to make sure that the cache policy overrides the default in order for objects from these transactions to be cached. Force the policy to override default HTTP rules by rebinding the cache policy with the -precedeDefRules YES switch.

5. **Verify the size of the object to be cached.**
   You can configure a content group with minimum, which by default is 0 KB, and maximum, which by default is 80 KB, response sizes for the objects to be cached. The object does not get cached if its size is not within the configured range. Additionally, verify that the cache expiry times are set to an appropriate value. For example, check for a very small

time limit, such as one second.

Run the following command from the command line interface of the appliance to display the size limits and expiry times for a specific content group:

show cache contentGroup <Content_Group_Name>

Following is an example of this command's output:

```
show cache contentGroup content1
    Name: content1
    Heuristic expiry time parameter: 10 percent
    Weak relative expiry time - Positive responses: 3600 secs
    Weak relative expiry time - Negative responses: 600 secs
    Hit parameters: NONE
    Invalidation Parameters: NONE
    Invalidation restricted to host: NO
    Ignore parameter value case: NO
    Match Request Cookies: NO
    Poll Every Time: NO
    Ignore reload request: YES
    Remove Response Cookies: YES
    Prefetch: YES
    Prefetch period: heuristic
    Current outstanding prefetches: 0
    Max outstanding prefetches: 4294967294
    Flashcache: NO
    Expire at last byte: NO
    Insert Via header: YES
    Insert Age header: YES
    Insert ETag header: YES
    Cache-control header: NONE
    Quick abort size: 4194303 KBytes (MAXIMUM)
    Minimum Response Size: 0 KBytes
    Maximum Response Size: 80 KBytes
    Memory usage: 0 Bytes
    Memory usage limit: UNLIMITED
    Ignore caching headers in request: YES
    Non-304 hits: 0
    304 hits: 0
    Cached objects: 0
    Number of times expired/flushed: 0
    MinHits configured: 0
    Always evaluate policies: NO
    Pinned: NO
 Done
```

In addition to the above steps for troubleshooting integrated caching issues, you can consider using the following troubleshooting techniques:

- Depending on the configuration of a policy, there are virtually an unlimited number of reasons for the policy not getting evaluated. If you have completed the preceding steps to troubleshoot the issue, consider completing the following procedure to troubleshoot the issue further:
  1. Flush the cache.
  2. Verify the value of the hit parameter for the policy by running the following command:
     show cache global
     1) Name: home_pol_1 State: ACTIVE Priority: 99
        Rule: URL CONTAINS home
        Action: NOCACHE
        Precede default HTTP rules: NO
        Hits : 29
  3. Send an HTTP request for the related object from a Web browser.
  4. Run the show cache global command again and verify that the value for the hit parameter has incremented.

  Depending on the policy receiving hits or not, you can determine whether the issue is due to the policy have not been configured correctly or to a more global cache setting.

Front End Optimization

Oct 10, 2017

Note: Front end optimization is available if you have an Enterprise or Platinum NetScaler license and are running NetScaler release 10.5 or later.

The HTTP protocols that underlie web applications were originally developed to support transmission and rendering of simple web pages. New technologies such as JavaScript and cascading style sheets (CSS), and new media types such as Flash videos and graphics-rich images, place heavy demands on front-end performance, that is, on performance at the browser level.

The NetScaler front end optimization (FEO) feature addresses such issues and reduces the load time and render time of web pages by:

- Reducing the number of requests required for rendering each page.
- Reducing the number of bytes in page responses.
- Simplifying and optimizing the content served to the client browser.

You can customize your FEO configuration to provide the best results for your users. NetScaler ADCs support numerous web content optimizations for both desktop and mobile users. The following tables describe the front-end optimizations provided by the FEO feature, and the operations performed on different types of files.

Optimizations Performed by the FEO Feature

Web Optimization	Problem	What NetScaler FEO feature does	Benefits
Inlining	Client browsers often send multiple requests to servers for loading external CSS, images, and JavaScript associated with the web page.	CSS inline JavaScript inline CSS combine	Loading the external CSS, images, and JavaScript inline with the HTML files improves page-rendering time. This optimization is beneficial for content that will be viewed only once, and for mobile devices that have limited cache sizes.
Minification	Data fetched from servers includes inessential characters such as white spaces, comments, and newline characters. The time that browsers spend in processing such data creates website latency.	CSS minification JavaScript minification Removal of HTML comments	Minified files consume less bandwidth and avoid the latency caused by special processing.

Web Optimization	Problem	What NetScaler FEO feature does	Benefits
Image optimization	Mobile browsers often have slow connection speeds and limited cache memory. Downloading images on mobile clients consumes more bandwidth, processing time, and cache space, resulting in web site latency.	JPEG optimization CSS image inlining Image shrink-to attributes GIF to PNG conversion HTML image inlining WebP image conversion JPEG, GIF, PNG to JPEG-XR image conversion	Reduces the image to the size indicated in image tag by NetScaler, enabling client browsers to load images faster.
Repositioning	Inefficient processing of external CSS, images, and JavaScript increases page-load time.	Image lazy loading CSS move to Head JavaScript move to end	Repositions HTML elements, to reduce rendering time for web pages and enable client browsers to load the objects faster.
Connection Management	Many browsers set limits on the number of simultaneous connections that can be established to a single domain. This can cause browsers to download webpage resources one at a time, resulting in higher browsers time.	Domain sharding	Overcomes the connection limitation, which improves page-rendering time by enabling client browsers to download more resources in parallel.

Web Optimizations performed on different file types

The following table lists the web optimizations that the NetScaler ADC performs on CSS, Images, JavaScript, and HTML:

Object	Optimization

CSS	• Minify linked CSS files. • Combine multiple linked CSS files that are present within the <head> tag into a single CSS file. • Convert linked CSS files to inline CSS files. • Convert CSS import rule to linked CSS. Note: This optimization works if you have not defined the scope and media attributes for the <import> tag and when the <import> tag immediately follows the <style> tag. • Within a linked CSS file, convert linked images to inline images. • Move a CSS present within the <body> tag of an HTML page to the <head> tag. Note: The <head> tag must already be present within the HTML script.
Images	• Optimize JPEG images by removing extraneous bytes. • Reduce image size by weakening the image quality to a value specified in FEO parameters. • Image shrink to attributes. • Convert linked images to inline images. Note: For animated images in GIF format, only this optimization is supported. • Convert non-animated images in GIF format to PNG format. • Reduce the image size to that specified on the web page, if the size specified on the web page is smaller • Convert images in GIF, PNG, JPEG format to WebP format • Convert images in JPEG format to JPER-XR format • Lazy loading.
JavaScript	• Minify linked JavaScript • Convert linked JavaScript to inline JavaScript. • Move JavaScript present in the <body> tag to the end of the <body> tag. Note: The size of the <body> tag must be lesser than 64 Kbytes.

	• Extend cache expiry period.
HTML	• Removal of Comments from HTML.

Note: The front end optimization feature supports ASCII characters only. It does not support the unicode character set.

After the NetScaler ADC receives the response from the server:

1. Parses the contents of the page, creates an entry in the cache (wherever applicable), and applies the FEO policy. For example, a NetScaler ADC can apply the following optimization rules:
   - Remove white spaces or comments present within a CSS or JavaScript.
   - Combine one or more CSS files to one file.
   - Convert GIF image format to PNG format.
2. Rewrites the embedded objects and saves the optimized content in the cache, with a different signature than the one used for the initial cache entry.
3. For subsequent requests, fetches the optimized objects from the cache, not from the server, and forwards the responses to the client.

*

Remove extraneous information such as white spaces and comments.
*

Remove extraneous information such as white spaces and comments.
**

The period during which the browser can use the cached resource without checking to see if fresh content is available on the server.

Configuring Front End Optimization

Aug 25, 2016

Optionally, you can change the values of the front end optimization global settings. Otherwise, begin by creating actions that specify the optimization rules to be applied to the embedded objects.

After configuring actions, create policies, each with a rule specifying a type of request for which to optimize the response, and associate the actions with the policies.

Note: The NetScaler ADC evaluates front end optimization policies at request time only, not at response time.
To put the policies into effect, bind them to bind points. You can bind a policy globally, so that it applies to all traffic that flows through the NetScaler ADC, or you can bind the policy to a load balancing or content switching virtual server of type HTTP or SSL. When you bind a policy, assign it a priority. A lower priority number indicates a higher value. The NetScaler ADC applies the policies in the order of their priorities.

Prerequisites for Front End Optimization

Front end optimization requires the NetScaler integrated caching feature to be enabled. Additionally, you must perform the following integrated caching configurations:

- Allocate cache memory.
- Set the maximum response size and memory limit for a default cache content group.

For more information on configuring integrated caching, see Integrated Caching.

Note: The term Integrated Cache can be interchangeably used with AppCache; note that from a functionality point of view, both terms mean the same.

At the command prompt, do the following:

1. Enable the front end optimization feature.
   enable ns feature FEO

2. Create one or more front end optimization actions.
   add feo action <name> [-imgShrinkToAttrib] [-imgGifToPng] ...

   Example: To add a front end optimization action for converting images in GIF format to PNG format and to extend cache expiry period:
   add feo action allact -imgGifToPng -pageExtendCache
3. [Optional] Specify non-default values for front end optimization global settings.
   set feo parameter [-cacheMaxage <integer>] [-JpegQualityPercent <integer>] [-cssInlineThresSize <integer>] [-inlineJsThresSize <integer>] [-inlineImgThresSize <integer>]

   Example: To specify the cache maximum expiry period:
   set feo parameter -cacheMaxage 10
4. Create one or more front end optimization policy.
   add feo policy <name> <rule> <action>

   Example: To add a front end optimization policy and associate it with the above specified *allact* action:
   >add feo policy pol1 TRUE allact

>add feo policy pol1 "(HTTP.REQ.URL.CONTAINS(\"testsite\"))" allact1

5. Bind the policy to a load balancing or content switching virtual server, or bind it globally.
   bind lb vserver <name> -policyName <string> -priority <num>

   bind cs vserver <name> -policyName <string> -priority <num>

   bind feo global <policyName> <priority> -type <type> <gotoPriorityExpression>

   Example: To apply the front end optimization policy to a virtual server named "abc":
   > bind lb vserver abc -policyName pol1 -priority 1 -type NONE
   Example: To apply the front end optimization policy for all the traffic reaching the ADC:
   > bind feo global pol1 100 -type REQ_DEFAULT
6. Save the configuration.
   save ns config

1. Enable the front end optimization feature using the command line interface.
2. Create a front end optimization action.
   Navigate to Optimization > Front End Optimization > Actions, click Add and create a front end optimization action by specifying the relevant details.

3. [Optional] Specify the front end optimization global settings.
   Navigate to Optimization > Front End Optimization, and on the right-pane, under Settings, click Change Front End Optimization settings and specify the front end optimization global settings.

4. Create a front end optimization policy.
   Navigate to Optimization > Front End Optimization > Policies, click Add and create a front end optimization policy by specifying the relevant details.

5. Bind the policy to a load balancing or content switching virtual server.
   1. Navigate to Optimization > Front End Optimization > Policies.
   2. Select a front end optimization policy and click Policy Manager.
   3. Under Front End Optimzation Policy Manager, bind the front end optimization policy to a load balancing or content switching virtual server.

Updated: 2015-01-12

The dashboard utility displays summary and detailed statistics in tabular and graphic formats. You can view the FEO statistics to evaluate your FEO configuration.

Optionally, you can also display statistics for an FEO policy, including the number of hits that the policy counter increments during policy based FEO.

Note: For more information about statistics and charts, see the Dashboard help on the Citrix NetScaler appliance.

To View FEO statistics by using the command line interface

At the command prompt, type the following commands to display a summary of FEO statistics, FEO policy hits and details, and detailed FEO statistics, respectively:

- stat feo
  Note: The **stat feo policy** command displays statistics only for advanced FEO policies.
- show feo policy <name>
- stat feo -detail

To view FEO statistics on the Dashboard

In the Dashboard utility, you can:

- Select **Front End Optimization** to display a summary of FEO statistics.
- Click the **Graphical View** tab to display the rate of requests processed by the FEO feature.

Sample Optimization

Apr 22, 2014

The following table lists some examples of content optimization actions that are applied on HTML content and the embedded objects within the HTML content.

Optimization rule	Sample
Collapse white spaces within an HTML page	Before: <title>Hello, world! </title>
	After: <title>Hello, world!</title>
Combine CSS	Before: <link rel="stylesheet" type="text/css" href="**sheet/abc.css**"> <link rel="stylesheet" type="text/css" href="**sheet/xyz.css**">
	After: <link rel="stylesheet" type="text/css" href="**sheet/abc.css+xyz.css**">
Inline CSS	Before <html> <head> <link rel="sheet" href="abc.css"/> </head> <body> Hi! </body> </html> Note: abc.css contains .Alice {location: Australia;} .Tom {location: Asia;}
	After <html> <head> <style> .Alice {location: Australia;} .Tom {location: Asia;} </style> </head> <body> Hi!

Optimization rule	Sample
	</body> Sample </html>
Move CSS to head	Before: <html> <head> </head> <body> <script src="abc.js" type="text/javascript"></script> <div class="monday tuesday> Hi! <style type="text/css"> .foo { day: wednesday; } </style> <link rel="stylesheet" type="text/css" href="styles/all_styles.css"> </body> </html>
	After: <html> <head> <style type="text/css"> .foo { day: wednesday; } </style> </head> <body> <script src="abc.js" type="text/javascript"></script> <div class="monday tuesday> Hi! <link rel="stylesheet" type="text/css" href="styles/all_styles.css"> </body> </html>

Minify JavaScript	Before:
	/* Remove this comment */
	document.write("abc " + state);
	state += 1; // Update this.

	After: document.write("abc "+state);state+=1;
Convert linked JavaScript to inline JavaScript	Before <html> <head> <script type="text/javascript" src="abc.js"></script> </head> <body>

Optimization rule	Sample
	 Hi! </body> </html> Note: abc.js contains /* contents of abc JavaScript file */
	After <html> <head> <script type="text/javascript"> /* contents of abc JavaScript file */ </script> </head> <body> Hi! </body> </html>

Content Accelerator

Nov 27, 2015

> **Important**
>
> The content accelerator feature is no longer supported on the NetScaler appliance.

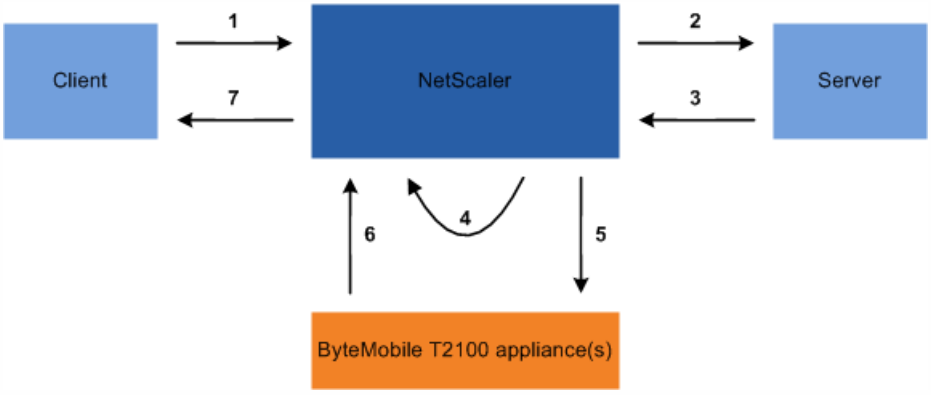
Content accelerator is a NetScaler feature that you can use in a Citrix ByteMobile T1100 deployment, to store data on a Citrix ByteMobile T2100 appliance. For more information about Citrix ByteMobile, see How ByteMobile Works.
Storing data on a T2100 appliance saves bandwidth and provides faster response times, because the NetScaler does not have to connect to the server for repeated requests of the same data.

Note: Content accelerator works with a Citrix ByteMobile platinum license. Contact customer support for more information and for obtaining the license.

Updated: 2015-05-20

When a load balancing or content switching virtual server receives a client request, the NetScaler appliance evaluates a content accelerator policy that you have bound to the virtual server. The policy filters the requests to identify the ones to which to apply the content accelerator feature.

Note: For HTTP requests, the content accelerator feature can serve partial content in response to single byte-range requests.
The following figure illustrates the operations that the appliance performs when a client request arrives at a virtual server configured to use the content accelerator feature:



The process flow is as follows:

1. Client sends request.
2. NetScaler forwards the request to the server.
3. Server responds with the predefined size of the response (specified by the accumResSize parameter of the add ca action command).
4. NetScaler computes a hash of the response sent by the server.

5. NetScaler looks up the hash on the T2100 appliance.
6. A successful lookup indicates that the data is available and the T2100 appliance sends the data to the NetScaler.

   Note:
   - When a lookup does not succeed, the NetScaler fetches all of the requested data from the server, and simultaneously serves the data to the client and updates the data on the T2100 appliance.
   - The T2100 appliance can be configured to specify the number of requests after which to cache the data.
7. NetScaler sends the response to the client.

Updated: 2013-12-16

Before configuring the content accelerator feature, you must enable it on the NetScaler appliance.

You can configure the content accelerator feature to use one or multiple T2100 appliances. You must add each T2100 appliance as a service and bind these services to a load balancing virtual server that is dedicated to distributing the load between the configured T2100 appliances.

You must also configure a content accelerator action to lookup the data on the T2100 appliance. The action must also specify the T2100 load balancing virtual server and the size of data (in KB) to be fetched from the server to calculate the hash.

The action must be bound to a content accelerator policy that defines the traffic on which to perform content acceleration. The content accelerator policy must be bound to a content switching or load balancing virtual server that receives client traffic. Alternatively, you can bind the policy globally to be applicable to all virtual servers.

Configuring content accelerator by using the command line interface

At the command prompt, do the following:

1. Enable the content accelerator feature.
   enable ns feature ca
2. Identify the T2100 appliances and add each as a service on the NetScaler appliance.
   add service <name> <IPAddress> <serviceType> <port>

   Example:
   > add service T2100-A 10.102.29.61 HTTP 30
   > add service T2100-B 10.102.29.62 HTTP 40
   > add service T2100-C 10.102.29.63 HTTP 50
   Note: The services must be of type HTTP only.
3. Create a load balancing virtual server for the T2100 appliances. Specify the token load balancing method and the rule shown in the following syntax.
   add lb vserver <name> <serviceType> <IPAddress> <port> -lbMethod TOKEN -rule "http.req.url.after_str(\"/lookup/\") alt http.req.url.path.SKIP(1).PREFIX(64)"

   Example:
   > add lb vserver T2100-lbvserver HTTP 10.102.29.64 99 -lbMethod TOKEN -rule "http.req.url.after_str(\"/lookup/\") alt

http.req.url.path.SKIP(1).PREFIX(64)"

4. Bind the T2100 services to the load balancing virtual server that you created for them.
   bind lb vserver <name> <serviceName>

   Example:
   > bind lb vserver T2100-lbvserver T2100-A
   > bind lb vserver T2100-lbvserver T2100-B
   > bind lb vserver T2100-lbvserver T2100-C
5. Define a content accelerator action.
   add ca action <name> -accumResSize <KBytes> -lbvserver <string> -type lookup

   Example:
   > add ca action ca_action1 -type lookup -lbvserver T2100-lbvserver -accumResSize 60
6. Define a content accelerator policy.
   add ca policy <name> -rule <expression> -action <name>

   Example: To create a content accelerator policy that caches all video formats.
   > add ca policy ca_mp4_pol -rule ns_video -action ca_action1
   where ns_video is a built-in expression.

7. Bind the content accelerator policy to either a virtual server that receives traffic or globally to the NetScaler system.
   bind lb vserver <name> -policyName <string>

   bind cs vserver <name> -policyName <string>

   bind ca global -policyName <string> -priority <num> -type <type>

   Example: To apply the content accelerator policy to a virtual server named "traf_rec"
   > bind lb vserver traf_rec -policyName ca_mp4_pol
   Example: To apply the content accelerator policy for all traffic reaching the NetScaler.
   > bind ca global -policyName ca_mp4_pol -priority 100 -type RES_DEFAULT
8. Save the configuration.
   save ns config

Configuring content accelerator by using the configuration utility

1. Navigate to System > Settings > Configure Advanced Features and select Content Accelerator.
2. Create a service for each of the T2100 appliances.
   1. Navigate to Traffic Management > Load Balancing > Services.
   2. Click Add and specify the relevant details. In the Server field, make sure you specify the IP address of the T2100 appliance. In the Protocol field select HTTP.
3. Create a virtual server and bind the T2100 services to it.
   1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
   2. Click Add and specify the relevant details.
   3. In the Method and Persistence tab, specify the Method as Token.
   4. In the Policies tab, specify the rule as http.req.url.after_str(\"/lookup/\") alt http.req.url.path.SKIP(1).PREFIX(64).
   5. In the Services tab, select the T2100 services that you want to bind to the virtual server.
4. Create a content accelerator action.
   1. Navigate to Optimization > Content Accelerator > Actions.

2. Specify the relevant details.

5. Create a content accelerator policy.
   1. Navigate to Optimization > Content Accelerator > Policies.
   2. Click Add, specify the policy rule, and associate the content accelerator action.
6. Bind the content accelerator policy globally or to a virtual server.
   1. Navigate to Optimization > Content Accelerator.
   2. Under the Content Accelerator Policy Manager [REQUEST] or Content Accelerator Policy Manager [RESPONSE] sections, bind the content accelerator policy globally or to a virtual server.

SPDY (Speedy)

May 20, 2015

Note: Supported from NetScaler 10.1 onwards.

SPDY is an open networking experimental protocol developed by Google to reduce the time taken by a client to load a web page in a browser. An application layer protocol, SPDY changes the way in which HTTP requests and responses are handled. SPDY offers the following advantages compared to a regular HTTP transaction:

- Multiplexed requests and responses—In a single SPDY session, multiple requests from the client can be sent over a single TCP connection to the server. This reduces the number of TCP connections and also optimizes usage of each TCP connection.
- Request prioritization—When requesting services from the server, a client can assign a priority to each request.
- Header Compression—SPDY compresses the HTTP request and response headers, saving bandwidth and reducing latency.
- Server push—The server can send data to the client before the client requests it.
- Security—SPDY is secure by design, because SSL is required for SPDY connections.

NetScaler supports the SPDY/2 and SPDY/3 (from NetScaler 10.5 onwards) versions.

Note: SPDY support depends on the browser version being used.

If you use a NetScaler appliance as a SPDY gateway for your servers, the servers do not have to support SPDY. The NetScaler appliance accepts the incoming SPDY requests, converts them, and sends them to the servers as HTTP requests. It also converts the HTTP responses and sends them to the clients as SPDY responses. While the key value of SPDY is reduced bandwidth consumption and faster communication with clients, an additional benefit of the NetScaler solution is that you avoid the time consuming task of upgrading your web servers and applications to support SPDY.

To use a NetScaler appliance as a SPDY gateway, you must enable SPDY on the appliance.

This document includes the following details:

- How SPDY Works over SSL
- Configuring SPDY on the NetScaler Appliance
- Troubleshooting for SPDY

Both ends of a SPDY connection must support the same version of SPDY. In addition, the clients must meet the following requirements:

- Support ZLIB compression and accept compressed data.
- Support the Next Protocol Negotiation (NPN) TLS extension, because NPN is used in the TLS handshake.

Updated: 2014-03-13

If SPDY is enabled, when the NetScaler appliance sees TLS ALPN extension with list of supported protocols in the Client Hello message, it responds with either SPDY/3 or SPDY/2 in the ALPN extension in its Server Hello.

NetScaler can also negotiate SPDY over NPN. When NetScaler sees an empty NPN extension in the Client Hello message, it responds with a list of the protocols that it supports. If SPDY is enabled on the NetScaler appliance, the appliance advertises HTTP/1.1 and SPDY/2 protocols. The client selects one protocol from this list and negotiates the protocol with

the server. Because sending the negotiated protocol in plain text would raise security issues, the client sends the Change Cipher Spec notification which defines the details of the encryption for the session, followed by the Next Protocol message, which contains the encrypted protocol that the client has chosen. The client then sends the Finished message. The NetScaler appliance decrypts the Next Protocol message, and then sends a Finished message.

A session is then established, and application data can be exchanged.

Note: The NPN extension is not supported on a NetScaler FIPS appliance, and with TLS protocol versions 1.1 and 1.2.

Updated: 2014-09-15

By default, SPDY is disabled on the NetScaler appliance. After you enable SPDY, the appliance advertises SPDY/2 and/or SPDY/3 along with HTTP/1.1 during an SSL handshake. To enable SPDY on the NetScaler appliance, you must enable SPDY in the HTTP profile bound to the SSL virtual server.

To configure SPDY by using the command line interface

At the command prompt, do the following:

1. Enable SPDY on a HTTP profile.
   set ns httpProfile <profileName> -SPDY <options>

   Example
   > set ns httpProfile profile1 -SPDY ENABLED
2. Bind the HTTP profile to a SSL virtual server.
   set lb vserver <ssl-vserver-name> -httpProfileName <httpProfile-with-spdy>

   Example
   > set lb vserver SPDY_LB -httpProfileName profile1
   Note: To apply SPDY globally, enable SPDY on the global HTTP profile (nshttp_default_profile).

You can view the statistics by using the following command:

stat protocol http -detail

To configure SPDY by using the configuration utility

1. Navigate to System > Profiles, and in the HTTP Profiles tab, update the profile on which you want to enable SPDY.
2. Navigate to Traffic Management > Load Balancing > Virtual Servers, and associate the HTTP profile to the appropriate SSL virtual server.

If SPDY sessions are not enabled even after performing the required steps, check the following conditions.

- If the client is using a Chrome browser, SPDY might not work in some scenarios because Chrome sometimes does not initiate TLS handshake.
- If there is a forward-proxy between the client and the NetScaler appliance, and the forward-proxy doesn't support SPDY, SPDY sessions might not be enabled.
- NetScaler does not support NPN over TLS 1.1/1.2. To use SPDY, the client should disable TLS1.1/1.2 in the browser.
- Similarly, if the client wants to use SPDY, SSL2/3 must be disabled on the browser.

Media Classification

Jun 22, 2015

Understanding the type of traffic in the network helps network administrators to manage bandwidth consumption for optimal network performance. The media classification mode monitors and displays the statistics of media traffic going through the NetScaler appliance.

With this mode enabled, a network administrators can collect stats showing the amount of data accessed, and the types of devices from which the media files have been accessed. The NetScaler appliance also supports byte-range requests in this mode.

Currently the NetScaler appliance can monitor and display statistics for the following media file types:

Media File Name	Media File Type
Microsoft Smooth Streaming	Video
Apple Live Streaming	Video
Audio Data Transport Stream (ADTS)	Audio
Advanced Audio Coding (AAC)	Audio
Flash Video (FLV)	Audio and Video
3GP	Audio and Video

The appliance can display stats for the following devices:

Device Platform	Device Type
iOS	iPad and iPod
Android	Mobiles and tablets
Laptop or Desktop	Windows laptop and desktop computers
Others	Other mobile devices (mobiles and tablets)

The network administrators can check the following stats counters to know the amount of data accessed through the NetScaler appliance for various media traffic types.

Media File Name	Stats Counter
Microsoft Smooth Streaming	• **mcmssmthstrmvid**—This counter records the total number of Microsoft Smooth Streaming videos served by the NetScaler appliance. • **Mcmssmthstrvidpl**—This counter records the total number of Microsoft Smooth Streaming video playlists served by the NetScaler appliance. • **Mcmssmthstrmvidbytes**—This counter records the total number of data bytes served for Microsoft Smooth Streaming media traffic on the NetScaler appliance. • **Mcmssmthstrmplvidbytespl**—This counter records the total number of Microsoft Smooth Streaming playlist bytes served by the NetScaler appliance.
Apple Live Streaming	• **mccaplelivestrmngvid**—This counter records the total number of Apple Live Streaming videos served by the NetScaler appliance. • **Mccapplelivestrmngvidpl**—This counter records the total number of Apple Live Streaming video playlists served by the NetScaler appliance. • **Mcapplelivestreamingvidbytes**—This counter records the total number of data bytes served for Apple Live Streaming media traffic on the NetScaler appliance. • **Mcapplelivestreamingplaylistvidbytespl**—This counter records the total number of Apple Live Playlist bytes served by the NetScaler appliance.
Audio Data Transport Stream (ADTS)	• **mcadtsaudio**—This counter records the total number of ADTS audio clips served by the NetScaler appliance. • **Mcadtsaudiobytes**—This counter records the total number of data bytes served for ADTS media traffic on the NetScaler appliance.
Advanced Audio Coding (AAC)	• **Mcaacaudio**—This counter records the total number of AAC audio clips served by the NetScaler appliance. • **Mcaacaudiobytes**—This counter records the total number of data bytes served for AAC media traffic on the NetScaler appliance.
Flash Video (FLV)	• **Mcflvvid**—This counter records the total number of flash videos served by the NetScaler appliance. • **Mcflvvidbytes**—This counter records the total number of data bytes served for flash videos on the NetScaler appliance.
3GP	• **mc3gpvidbytes**—This counter records the total number of data bytes served for 3GP media traffic on the NetScaler appliance.

The NetScaler appliance detects media file types by their signatures in the *initial body bytes* of the responses. For example, the initial body bytes for an mp4 file has the following signature in the response:

....ftypmp42 ....isommp42....moov...lmvhd.....c.!.c.!..

The NetScaler appliance detects the client device type by the *user agent string* that the client device includes in the HTTP

GET request. For example, a windows phone using a UC browser will have the following user agent string in the HTTP GET request:

User-Agent: **UCWEB**/2.0 (**Windows**; U; wds 8.10; en-US; HTC; 8X by HTC) U2/1.0.0

By default, media classification is disabled on the NetScaler appliance. You have to enable the mode before using it.

To enable media classification by using the command line interface

At the command prompt, type:

enable ns mode Mediaclassification

To enable media classification by using the configuration utility

- Enable media classification on NetScaler appliance
  Navigate to **System** > **Settings** > **Configure Modes** and select **Media Classification**.
- View media traffic statistics on the NetScaler appliance
  Navigate to **Optimization** and click **Media Classification** to view the media traffic statistics.

You can view the media traffic statistics in the dashboard utility or using the command line interface. The dashboard utility displays summary and detailed statistics in a tabular and graphic format.

Note: For more information about statistics and charts, see the Dashboard help on your Citrix NetScaler appliance.

To View media classification statistics by using the command line interface

At the command prompt, type one of the following commands to display a summary of media classification statistics, display detailed statistics, or clear the display:

- stat Mediaclassification
- stat Mediaclassification -detail
- stat Mediaclassification -clearstats

To view Media Classification statistics on the Dashboard

In the Dashboard utility, you can display the following types of media classification statistics:

- Select **Media Classification** to display a summary of the media traffic statistics.
- To display detailed media traffic statistics, click the **Details**.
- To clear the media traffic statistics, click **Clear**.

Reputation

Dec 09, 2016

Citrix offers reputation based security. Using reputation assessment to determine the risk of processing requests, you can take actions such as blocking or dropping certain requests to improve the performance of your application.

The NetScaler IP reputation feature uses IP reputation checks to prevent Zero day attacks and provide protection against malicious sources associated with web attacks, phishing activity, or web scanning.

For additional details, see IP Reputation.

IP Reputation

Jan 26, 2017

IP reputation is an extremely effective tool in identifying the IP address that is sending unwanted requests. You can use the IP reputation list to preemptively reject requests that are coming from the IP with the bad reputation. For example, you can use this feature to optimize application firewall performance by filtering out the requests that you do not want to process. You can reset or drop the connection, or you can configure a responder policy to take a specific responder action.

Following are some examples of attacks that you can prevent by using IP Reputation:

- **Virus Infected personal computers** (home PCs) are the single biggest source of Spam on the internet. IP Reputation can identify the IP address that is sending unwanted requests. IP reputation can be especially useful for blocking large scale DDoS, DoS, or anomalous syn flood attacks from known infected sources.
- **Centrally managed and automated botnet** attacks have gained popularity for stealing passwords, because it doesn't take long when hundreds of computers work together to crack your password. It is easy to launch botnet attacks to figure out passwords that use commonly used dictionary words.
- **Compromised web-server** attacks are not as common as they used to be, because awareness and server security have increased, so hackers and spammers look for easier targets. There are still web servers and online forms that hackers can compromise and use to send spam (often the more vicious types, such as viruses and porn) but usually this type of activity is easier to detect and and quickly shut down, or block with a reputation list such as SpamRats.
- **Windows Exploits** (such as Active IPs offering/distributing malware, shell code, rootkits, worms or viruses).
- **Known spammers and hackers**.
- **Mass e-mail marketing campaigns**.
- **Phishing Proxies** (IP addresses hosting phishing sites, and other fraud such as ad click fraud or gaming fraud).
- **Anonymous proxies** (IPs providing proxy and anonymization services including The Onion Router aka TOR).

A NetScaler appliance uses **Webroot** as the service provider for the dynamically generated malicious IP database and the metadata for those IP addresses. Metadata might include geolocation details, threat category, threat count, and so on. The Webroot threat Intelligence engine receives real-time data from millions of sensors. It automatically and continuously captures, scans, analyses and scores the data, using advanced machine learning and behavioral analysis. Intelligence about a threat is continually updated.

As soon as a threat is detected anywhere in the network, the IP address is flagged as malicious and all appliances connected to the network are immediately protected. The dynamic changes in the IP addresses are processed with high speed and accuracy by leveraging advanced machine learning.

As stated in the datasheet from Webroot, the Webroot's sensor network identifies many key IP threat types, including spam sources, Windows exploits, botnets, scanners, and others. (See the flow diagram on the datasheet)

The NetScaler appliance uses an iprep client process to get the database from Webroot. The iprep client uses the HTTP GET method to get the absolute IP list from Webroot for the first time. Subsequently, it checks delta changes once every 5 minutes.

> ## Important
>
> Make sure the NetScaler appliance has Internet access and DNS is configured before you use the IP Reputation feature.
>
> To access the webroot database, the NetScaler appliance should be able to connect to **api.bcti.brightcloud.com** on **port 443**.

Each node in the High Availability (HA) or Cluster deployment gets the database directly from the webroot and should be able to access this FQDN (Fully Qualified Domain Name).

Webroot hosts it's reputation database in AWS currently. Therefore, NetScaler should be able to resolve AWS domains for downloading the reputation db. Also, firewall should be open for AWS domains.

NetScaler applaince should be able to connect to **wiprep-rtu.s3-us-west-2.amazonaws.com** on **port 443** to obtain IP data from AWS.

Note

In a HA pair, NSPPE might fail with high CPU and insufficient memory due to the MEM_NETWORK and MEM_IPREPUTATION modules. These modules consume high CPU and memory. When this happens, it is recommended to test the NetScaler appliance by disabling IP reputation feature using the following command:

- disable ns feature Rep

Note that each packet engine requires at least 4 GB to function properly when IP Reputation feature is enabled.

PI Expressions: The IP Reputation feature can be configured by using PI expressions (NetScaler default syntax expressions) in the policies bound to supported modules such as application firewall and responder. Following are two examples showing expressions that can be used to detect whether the client IP address is malicious

1. **CLIENT.IP.SRC.IPREP_IS_MALICIOUS**: This expression evaluates to TRUE if the client is included in the malicious IP list.
2. **CLIENT.IP.SRC.IPREP_THREAT_CATEGORY (CATEGORY)**: This expression evaluates to TRUE if the client IP is malicious IP and is in the specified threat category.

Following are the possible values for the threat category:

SPAM_SOURCES,

WINDOWS_EXPLOITS,

WEB_ATTACKS,

BOTNETS,

SCANNERS,

DOS,

REPUTATION,

PHISHING,

PROXY,

NETWORK,

CLOUD_PROVIDERS

MOBILE_THREATS.

> **Note**
>
> The IP reputation feature can check both source and destination IP addresses. It can also detect malicious IPs in the header. If the PI Expression in a policy can identify the IP address, the IP reputation check can determine whether it is malicious.

IPRep log message. The /var/log/iprep.log file contains useful messages that capture information about communication with the Webroot database. The information can be about the credentials used during Webroot communication, failure to connect with Webroot, what is included in an update (such as number of IP addresses in the database), and so on.

Creating a blacklist or whitelist of IPs using policy data set. You can maintain a whitelist to allow access to specific IP addresses that are blacklisted in the Webroot database. You can also create a customized blacklist of IP addresses to supplement the Webroot reputation check. These lists can be created by using policy **data set**. A data set is a specialized form of pattern set that is ideally suited for IPv4 address matching. To use data sets, first create the data set and bind IPv4 addresses to it. Then, when you configure a policy for comparing a string in a packet, use an appropriate operator and pass the name of the pattern set or data set as an argument.

To use the dataset to create a customized whitelist of addresses to treat as exceptions during IP reputation evaluation, configure the policy so that the PI expression evaluates to False even if an address in the whitelist is listed as malicious by Webroot (or any service provider).

Enabling or disabling IP reputation. IP reputation is a part of the general reputation feature, which is license based. When you enable or disable the reputation feature, it enables or disables IP Reputation.

General procedure. Deploying IP reputation involves the following tasks

- Verify that the license installed on the NetScaler appliance has IP reputation support. Platinum and standalone application firewall licenses support the IP reputation feature.
- Enable the IP reputation and application firewall features.
- Add an application firewall profile.
- Add an application firewall policy using the PI expressions to identify the malicious IP addresses in the IP Reputation database.
- Bind the application firewall policy to an appropriate bind point.
- Verify that any request received from a malicious address gets logged in the ns.log file to show that the request was processed as specified in the profile.

To enable IP reputation using CLI, you can use the following commands:

> **enable feature** [**rep** | **reputation**]

> **disable feature** [**rep** | **reputation**]

The following examples show how you can add an application firewall policy using the PI expression to identify malicious addresses. You can use the built-in profiles, or add a new profile, or configure an existing profile to invoke the desired action when a request matches a policy match.

Examples 3 and 4 show how to create a policy dataset to generate a Black (to be blocked) or White (to be allowed) list of IP addresses.

Example 1

The following command creates a policy that identifies malicious IP addresses and block the request if a match is triggered:

```
> add appfw policy pol1 CLIENT.IP.SRC.IPREP_IS_MALICIOUS APPFW_BLOCK
```

Example 2

The following command creates a policy that uses the reputation service to check the client IP address in a specific header (X-Forwarded-For) and reset the connection if a match is triggered:

```
> add appfw policy pol1 "HTTP.REQ.HEADER(\"X-Forwarded-
For\").TYPECAST_IP_ADDRESS_AT.IPREP_IS_MALICIOUS" APPFW_RESET
```

Example 3

The following example shows how to add a list to add exceptions that allow specified IP addresses:

```
> add policy dataset Allow_list ipv4

> bind policy dataset Allow_list 10.217.25.17 -index 1

> bind policy dataset Allow_list 10.217.25.18 -index 2
```

Example 4

The following example shows how to add the customized list to flag specified IP addresses as malicious:

```
> add policy dataset Block_List ipv4

> bind policy dataset Block_List 10.217.31.48 -index 1

> bind policy dataset Block_List 10.217.25.19 -index 2
```

Example 5

The following example shows a policy expression to block the client IP if it matches an IP address configured in the customized Block_list (example 4) or if it matches an IP address listed in the Webroot database unless relaxed by inclusion in the Allow_list (example 3).

```
> add appfw policy "Ip_Rep_Policy" "((CLIENT.IP.SRC.IPREP_IS_MALICIOUS ||
CLIENT.IP.SRC.TYPECAST_TEXT_T.CONTAINS_ANY(\"Block_List\")) && !
(CLIENT.IP.SRC.TYPECAST_TEXT_T.CONTAINS_ANY(\"Allow_List\")))" APPFW_BLOCK
```

Using Proxy server

If the NetScaler appliance does not have direct access to the Internet and is connected to proxy, use the following

command to configure the iprep client to send requests to the proxy.

> set reputation settings –proxyServer <proxy server ip> -proxyPort <proxy server port>

Example

> set reputation settings proxyServer 10.102.30.112 proxyPort 3128

> set reputation settings –proxyServer testproxy.citrite.net –proxyPort 3128

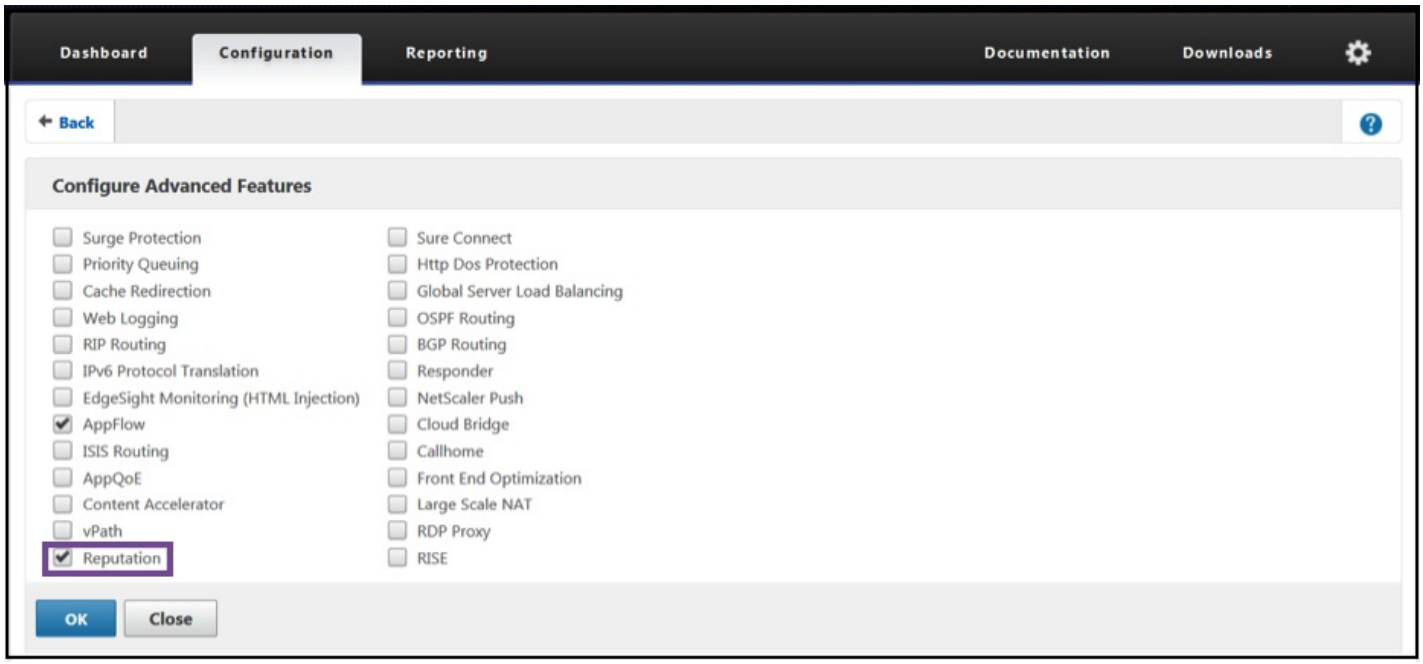
> unset reputation settings –proxyserver –proxyport

> sh reputation settings

> **Note**
>
> The Proxy Server IP can be an IP address or a fully qualified domain name (FQDN).

To enable reputation (which enables IP reputation) feature in GUI

Navigate to the **System** -> **Settings**. In the **Modes and Features** section, click the link to access the **Configure Advanced Features** pane and enable the **Reputation** check box. Click **OK**.

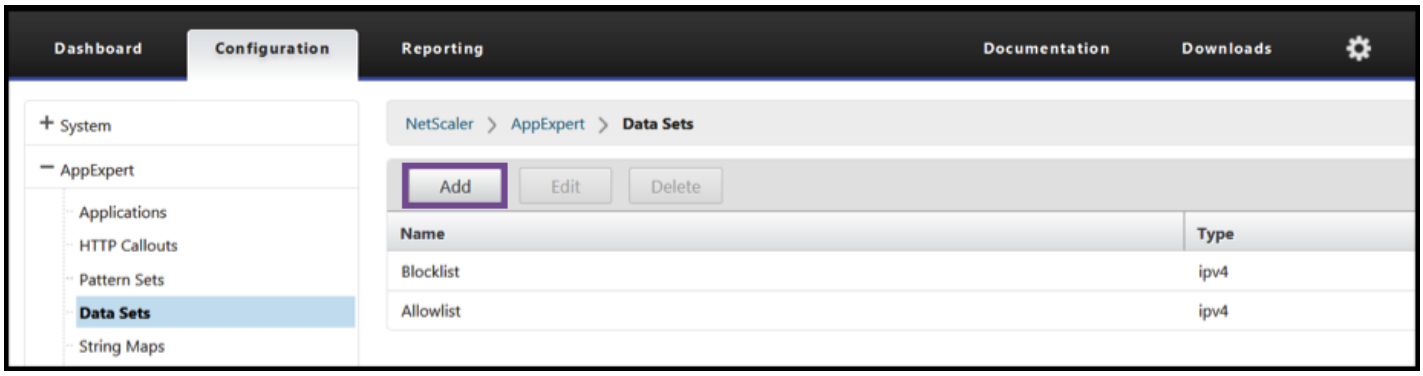


To configure a proxy server by using the configuration utility

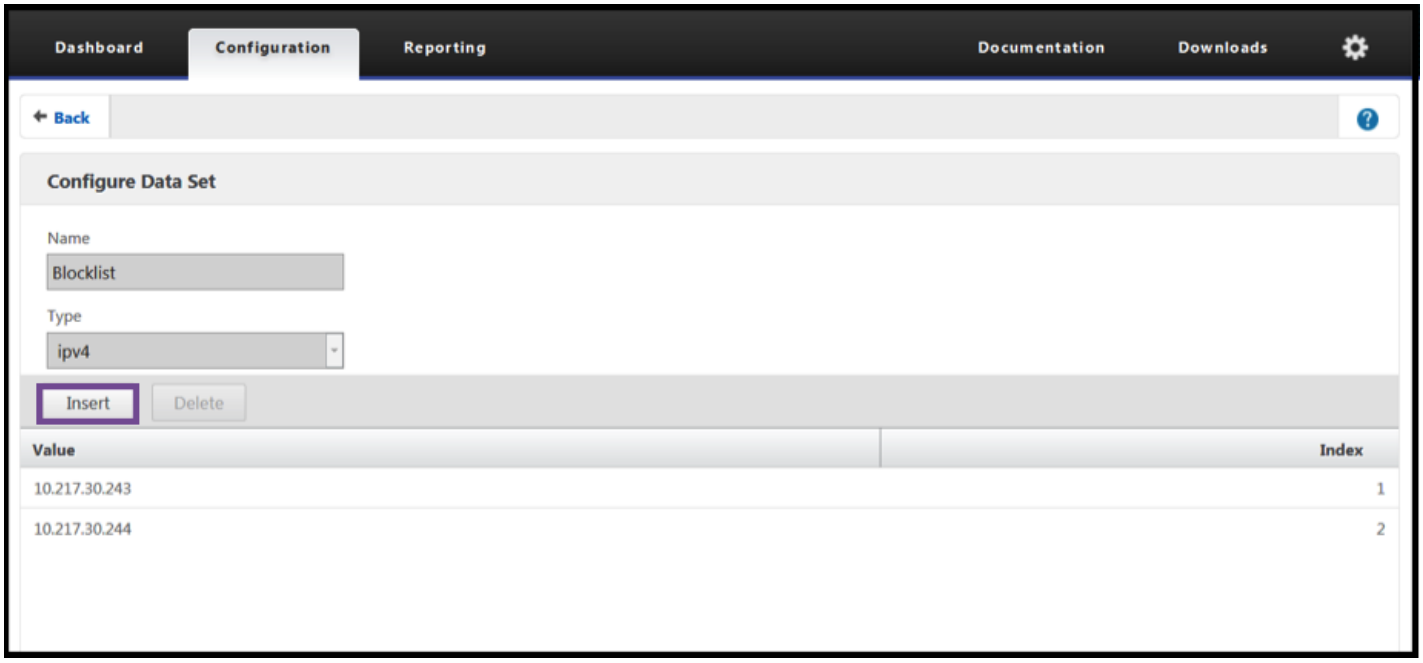
1. On the configuration tab, navigate to **Security** > **Reputation**. Under **Settings**, click **Change Reputation Settings** to configure a proxy server. You can also enable or disable the reputation feature. **Proxy Server** can be an IP address or a fully qualified domain name (FQDN). **Proxy por**t accepts values between [1 – 65535].

To use a dataset to create a whitelist (list of safe IPs) and blacklist (list of unsafe IPs) of Client IP addresses

- On the **Configuration** tab, navigate to **AppExpert** > **Data Sets**.
- Click **Add**.



- In the **Create Data Set** (or **Configure Data set**) pane, provide a meaningful name for the list of the IP addresses. The name should reflect the purpose of the list. For example, you could use a name such as *whitelist* or *Allow_list* when creating a list of IP addresses you would like to exempt from the action taken when the IP Reputation check determines that the source IP matches an IP address designated as a malicious IP in the webroot database. Similarly, use names such as *Block_list* or *Malicious_ip_list* if you are adding a list of IP addresses you want to flag as malicious to supplement the webroot database.
- Select ***Type** as **IPv4**.
- Click **Insert** to add a new entry.



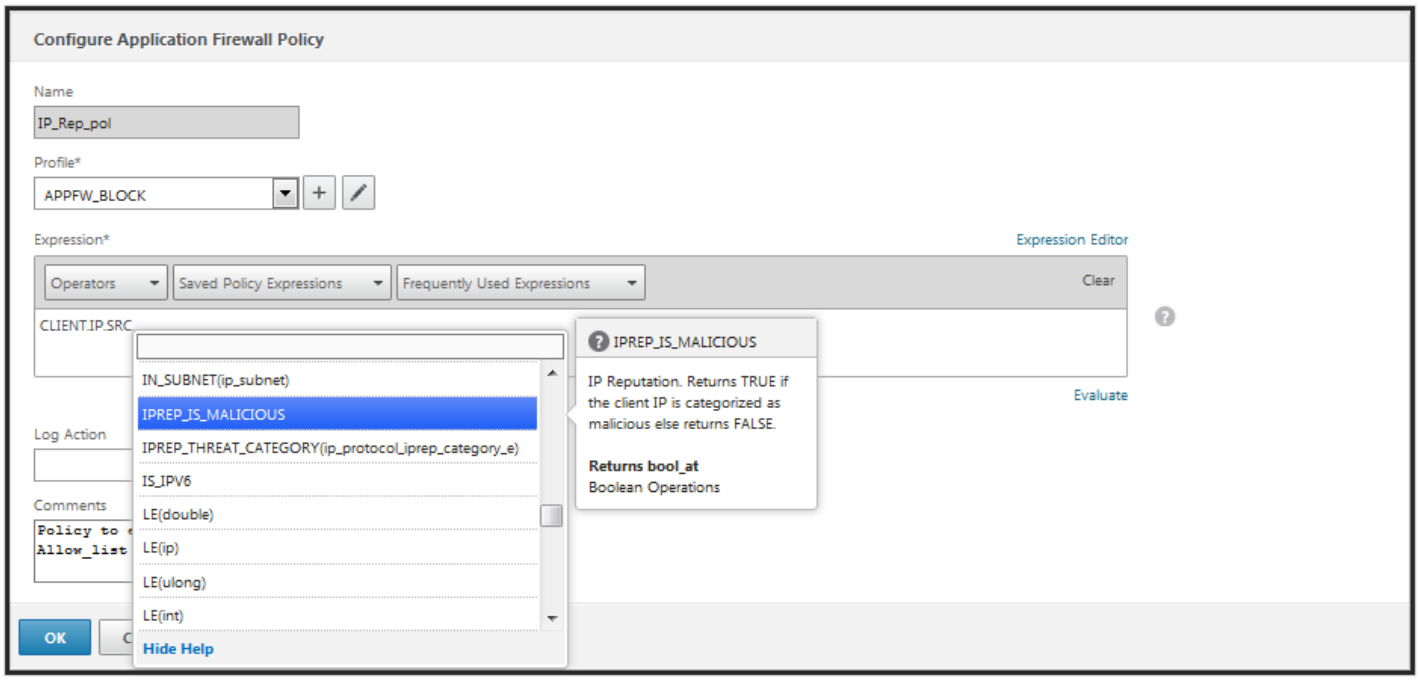
- In the Configure Policy dataset binding pane, add an IPv4 format IP address in the *Value input box.
- Provide an index.
- Add a comment that explains the purpose of the list. This step is optional, but is recommended because a descriptive comment is quite helpful in managing the list.

Similarly, you can create a Block_list and add the IP addresses that are to be considered malicious.

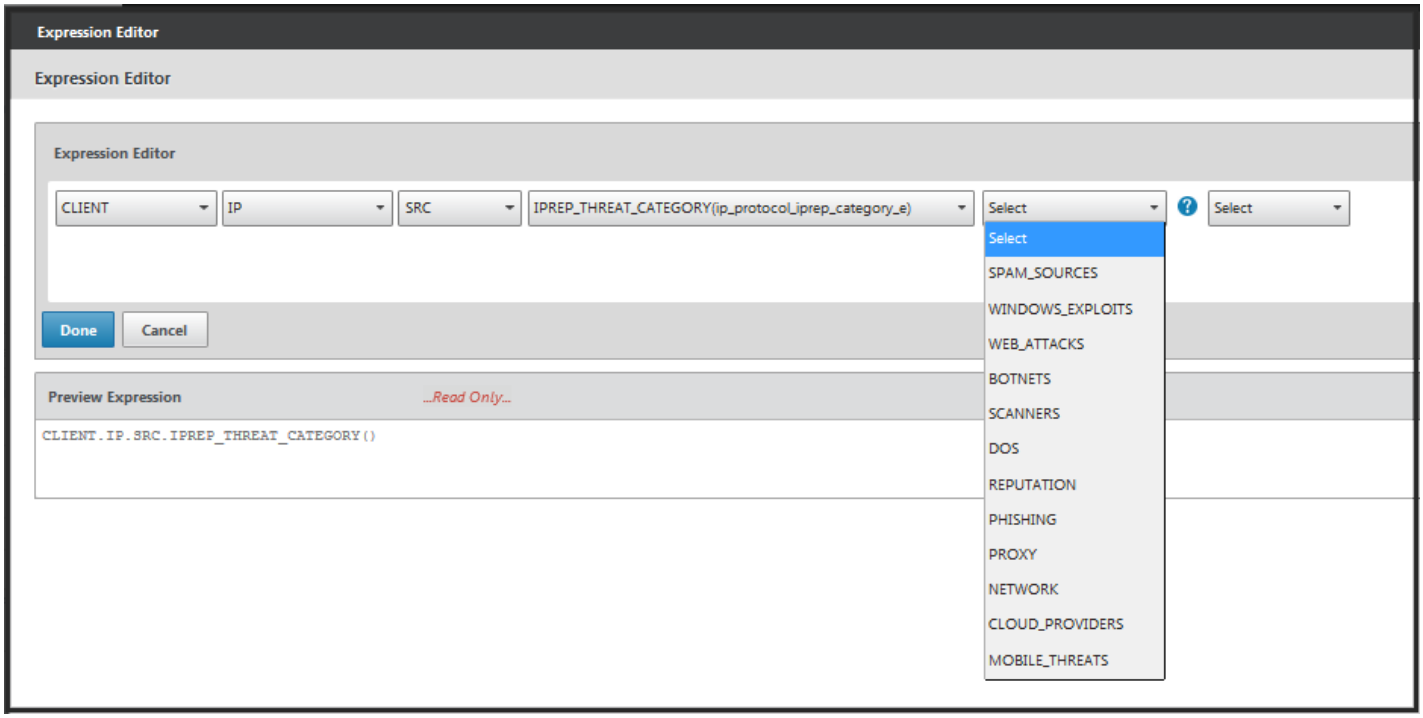
Also see, http://docs.citrix.com/en-us/netscaler/11/appexpert/pattern-sets-data-seta.html for additional details regarding using data sets and configuring default syntax policy expressions.

To configure an application firewall policy by using the configuration utility

1. On the **Configuration** tab, navigate to **Security** > **Application Firewall** > **Policies** > **Firewall**. Click **Add** to add a new policy using the PI expressions to use IP reputation.



You can also use the Expression editor to build your own policy expression. The drop-down menu shows preconfigured options that are quite useful for configuring an expression using the threat categories.



- Quickly and accurately stop bad traffic at the network's edge from known malicious IP addresses posing different types of threats. You can block the request without parsing the body.
- Dynamically configure IP reputation functionality for multiple applications.
- Secure your network against data breach without a performance penalty, and consolidate protections onto a single services fabric using fast and easy deployments.
- You can do IP Reputation checks on source as well as destination IPs.
- You can also inspect the headers to detect malicious IPs.
- IP reputation check is supported in both forward proxy and reverse proxy deployments.
- The iprep process connects with Webroot and updates the database every 5 minutes.
- Each node in the High Availability (HA) or Cluster deployment gets the database from Webroot.
- The IP reputation data is shared across all partitions in admin-partition deployments.
- You can use an AppExpert data set to create lists of IP addresses to add exceptions for IPs blacklisted in the Webroot database. You can also create your own customized blacklist to designate specific IPs as malicious.
- The iprep.db file is created in the /var/nslog/iprep folder. Once created, it is not deleted even if the feature is disabled.
- When the reputation feature is enabled, the NetScaler Webroot database is downloaded. After that, it is updated every 5 minutes.
- The Webroot database major version is currently version: 1.
- The minor version gets updated every day. The update version is incremented after every 5 minutes and is reset back to 1 when the minor version is incremented.
- PI expressions enable you to use IP reputation with other features, such as responder and rewrite.
- The IP addresses in the database are in decimal notation.

- If you cannot see the reputation feature in GUI, verify that you have the right license

- Monitor the messages in /var/log/iprep.log for debugging.
- **Webroot connectivity**: If you see the "ns iprep: Not able to connect/resolve WebRoot" message, make sure that the appliance has internet access and DNS is configured.
- **Proxy server**: If you see the "ns iprep: iprep_curl_download:88 curl_easy_perform failed. Error code: 5 Err msg:couldnt resolve proxy name" message, make sure that the proxy server configuration is accurate.
- **IP Reputation feature not working**: The iprep process takes about five minutes to start after you enable the reputation feature. The IP reputation feature might not work for that duration.

SSL Offload and Acceleration

Mar 28, 2017

A Citrix® NetScaler® appliance configured for SSL acceleration transparently accelerates SSL transactions by offloading SSL processing from the server. To configure SSL offloading, you configure a virtual server to intercept and process SSL transactions, and send the decrypted traffic to the server (unless you configure end-to-end encryption, in which case the traffic is re-encrypted). Upon receiving the response from the server, the appliance completes the secure transaction with the client. From the client's perspective, the transaction seems to be directly with the server. A NetScaler configured for SSL acceleration also performs other configured functions, such as load balancing.

Configuring SSL offloading requires an SSL certificate and key pair, which you must obtain if you do not already have an SSL certificate. Other SSL-related tasks that you might need to perform include managing certificates, managing certificate revocation lists, configuring client authentication, and managing SSL actions and policies.

A non-FIPS NetScaler appliance stores the server's private key on the hard disk. On a FIPS appliance, the key is stored in a cryptographic module known as a hardware security module (HSM). Only the MPX 9700/10500/12500/15500 appliances support a FIPS card, so other NetScaler models cannot be equipped with an HSM.

Beginning with release 10.5, build 52.1115.e, all NetScaler appliances that do not support a FIPS card (including virtual appliances) support the Thales nShield® Connect external HSM. (MPX 9700/10500/12500/15500 appliances do not support an external HSM.)

Note: FIPS-related options for some of the SSL configuration procedures described in this document are specific to a FIPS-enabled NetScaler.

Configuring SSL Offloading

Jun 03, 2015

To configure SSL offloading, you must enable SSL processing on the NetScaler appliance and configure an SSL based virtual server that will intercept SSL traffic, decrypt the traffic, and forward it to a service that is bound to the virtual server. To secure time-sensitive traffic, such as media streaming, you can configure a DTLS virtual server.To enable SSL offloading, you must import a valid certificate and key and bind the pair to the virtual server.

To configure SSL offloading, see the following sections:

- Enabling SSL Processing
- Configuring Services
- Configuring an SSL-Based Virtual Server
- Configuring an HTTPS Virtual Server to accept HTTP Traffic
- Binding Services to the SSL-Based Virtual Server
- Adding or Updating a Certificate-Key Pair
- Binding the Certificate-Key Pair to the SSL-Based Virtual Server
- Configuring an SSL Virtual Server for Secure Hosting of Multiple Sites
- Support for SNI on the Back-End Service
- Configuring a DTLS Virtual Server
- DTLS Profile
- Importing SSL Files from Remote Hosts
- SSL Profiles
- Enabling Stricter Control on Client Certificate Validation
- Graceful Cleanup of SSL Sessions

Enabling SSL Processing

Nov 11, 2013

To process SSL traffic, you must enable SSL processing. You can configure SSL based entities, such as virtual servers and services, without enabling SSL processing, but they will not work until SSL processing is enabled.

At the command prompt, type:

- enable ns feature ssl
- show ns feature

Example

```
> enable ns feature SSL
 Done
> show ns feature

      Feature                Acronym          Status
      -------                -------          ------
1)    Web Logging            WL               OFF
2)    Surge Protection       SP               ON
3)    Load Balancing         LB               ON
.
.
.
9)    SSL Offloading         SSL              ON
.
.
.
24)   NetScaler Push         push             OFF
Done
```

Navigate to System > Settings and, in the Modes and Features group, select Configure Basic Features, and select SSL Offloading.

Configuring Services

Oct 06, 2016

On the NetScaler appliance, a service represents a physical server or an application on a physical server. Once configured, services are in the disabled state until the appliance can reach the physical server on the network and monitor its status.

At the command prompt, type the following commands to add a service and verify the configuration:

- add service <name> (<IP> | <serverName>) <serviceType> <port>
- show service <serviceName>

```
> add service SSL1 192.168.0.12 SSL 443

 Done

> sh service SSL1

        SSL1 (192.168.0.12:443) - SSL

        State: DOWN

        Last state change was at Thu Oct  6 17:15:41 2016

        Time since last state change: 0 days, 00:00:07.990

        Server Name: 192.168.0.12

        Server ID : None        Monitor Threshold : 0

        Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits

        Use Source IP: NO

        Client Keepalive(CKA): NO

        Access Down Service: NO

        TCP Buffering(TCPB): NO
```

```
        TCP Buffering(TCPB): NO

        HTTP Compression(CMP): NO

        Idle timeout: Client: 180 sec   Server: 360 sec

        Client IP: DISABLED

        Cacheable: NO

        SC: OFF

        SP: ON

        Down state flush: ENABLED

        Monitor Connection Close : NONE

        Appflow logging: ENABLED

        Process Local: DISABLED

        Traffic Domain: 0

1)      Monitor Name: tcp-default

                State: DOWN     Weight: 1       Passive: 0

                Probes: 2       Failed [Total: 1 Current: 1]

                Last response: Failure - Time out during TCP connection establishment stage

                Response Time: 0.0 millisec

 Done
```

To modify a service, use the set service command, which is just like using the add service command, except that you enter the name of an existing service. To remove a service, use the rm service command, which accepts only the <name> argument.

Navigate to Traffic Management > Load Balancing > Services, create a service, and specify the protocol as SSL.

Configuring an SSL-Based Virtual Server

Feb 13, 2017

Secure sessions require establishing a connection between the client and an SSL-based virtual server on the NetScaler appliance. The SSL virtual server intercepts SSL traffic, decrypts it and processes it before sending it to services that are bound to the virtual server.

Note: The SSL virtual server is marked as down on the NetScaler appliance until a valid certificate / key pair and at least one service are bound to it. An SSL based virtual server is a load balancing virtual server of protocol type SSL or SSL_TCP. The load balancing feature must be enabled on the NetScaler.

At the command prompt, type the following commands to create an SSL-based virtual server and verify the configuration:

- add lb vserver <name> (serviceType) <IPAddress> <port>
- show lb vserver <name>

Example

```
> add lb vserver vssl  SSL 10.102.29.133 443
 Done
> show ssl vserver vssl

        Advanced SSL configuration for VServer vssl:
        DH: DISABLED
        Ephemeral RSA: ENABLED         Refresh Count: 0
        Session Reuse: ENABLED         Timeout: 120 seconds
        Cipher Redirect: DISABLED
        SSLv2 Redirect: DISABLED
        ClearText Port: 0
        Client Auth: DISABLED
        SSL Redirect: DISABLED
        Non FIPS Ciphers: DISABLED
        SSLv2: DISABLED SSLv3: ENABLED  TLSv1: ENABLED

1)      Cipher Name: DEFAULT
        Description: Predefined Cipher Alias
 Done
```

To modify the load balancing properties of an SSL virtual server, use the set lb vserver command, which is just like using the add lb vserver command, except that you enter the name of an existing vserver. To modify the SSL properties of an SSL-based virtual server, use the set ssl vserver command. For more information, see Customizing the SSL Configuration.

To remove an SSL virtual server, use the rm lb vserver command, which accepts only the <name> argument.

Navigate to Traffic Management > Load Balancing > Virtual Servers, create a virtual server, and specify the protocol as SSL.

Configuring an HTTPS Virtual Server to accept HTTP Traffic

Jun 17, 2016

A user might attempt to access a secure web site by sending an HTTP request. You can drop such requests or redirect the request to the secure web site. In earlier releases, to redirect the request to the secure web site, you were required to do the following:

- Add HTTP and HTTPS virtual servers with the same IP address but different ports.
- Add a responder action that redirects all traffic to the HTTPS virtual server.
- Add a responder policy specifying the above action, and bind the policy to the HTTP virtual server.

From release 11.1, you can configure an HTTPS virtual server to also process all HTTP traffic. That is, if HTTP traffic is received on the HTTPS virtual server, the appliance internally prepends "**https://**" to the incoming URL or redirects the traffic to another HTTPS URL, depending on the option configured.

To achieve this, two new parameters, **-httpsRedirectUrl** and **-redirectFromPort** are added to the "add lb vserver" command.

- **redirectFromPort**: All HTTP traffic received on this port is prefixed with https:// in the URL and redirected.
- **httpsRedirectUrl**: All HTTP traffic received on the port specified in the **-redirectFromPort** parameter is redirected to this URL. For example, all HTTPS traffic received on http://www.example.com is redirected to https://www.sample.com.

To configure HTTP to HTTPS redirect by using the NetScaler command line

At the command prompt, type:

add lb vserver <name> <serviceType> **-redirectFromPort** <port | *> **-httpsRedirectUrl** <URL>

```
> add lbvserver lbvip2 SSL 1.2.1.2 443 -redirectFromPort 80 -httpsRedirectUrl https://www.example.com

 Done
```

To configure HTTP to HTTPS redirect by using the NetScaler GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
2. Add a virtual server of type **SSL** and click **OK**.
3. Edit **Basic Settings**, click **More**, and add values for **Redirect From Port** and **HTTPS Redirect URL**.

Binding Services to the SSL-Based Virtual Server

Feb 13, 2017

For the NetScaler appliance to forward decrypted SSL data to servers in the network, services representing these physical servers must be bound to the virtual server that receives the SSL data.

Because the link between the NetScaler and the physical server is typically secure, data transfer between the appliance and the physical server does not have to be encrypted. However, you can provide end-to end-encryption by encrypting data transfer between the NetScaler and the server. For details, see Use Case 1: Configuring SSL Offloading with End-to-End Encryption.

Note: The Load Balancing feature should be enabled on the NetScaler appliance before you bind services to the SSL based virtual server.

At the command prompt, type the following commands to bind the service to the virtual server and verify the configuration:

- bind lb vserver <name> <serviceName>
- show lb vserver <name>

Example

```
> bind lb vserver vssl ssl1
 Done
> show lb vserver vssl
      vssl (10.102.29.133:443) - SSL  Type: ADDRESS
      State: DOWN[Certkey not bound]
      Last state change was at Thu Nov 12 05:31:17 2009 (+485 ms)
      Time since last state change: 0 days, 00:08:52.130
      Effective State: DOWN
      Client Idle Timeout: 180 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      No. of Bound Services :  1 (Total)       1 (Active)
      Configured Method: LEASTCONNECTION
      Mode: IP
      Persistence: NONE
      Vserver IP and Port insertion: OFF
      Push: DISABLED  Push VServer:
      Push Multi Clients: NO
      Push Label Rule: none

1) ssl1 (10.102.29.252: 80) - HTTP State: UP    Weight: 1
 Done
```

At the command prompt, type the following command:

unbind lb vserver <name> <serviceName>

Example

unbind lb vserver vssl ssl1

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open a virtual server, and click in the Services section to bind a service to the virtual server.

Adding or Updating a Certificate-Key Pair

Mar 28, 2017

For any SSL transaction, the server needs a valid certificate and the corresponding private and public key pair. The SSL data is encrypted with the server's public key, which is available through the server's certificate. Decryption requires the corresponding private key.

Because the NetScaler appliance offloads SSL transactions from the server, the server's certificate and private key must be present on the appliance, and the certificate must be paired with its corresponding private key. This certificate-key pair must then be bound to the virtual server that processes the SSL transactions.
Note: From release 11.0, the default certificate on a NetScaler appliance is 2048-bits. In earlier builds, the default certificate was 512-bits or 1024-bits. After upgrading to release 11.0, you must delete all your old certificate-key pairs starting with "ns-", and then restart the appliance to automatically generate a 2048-bit default certificate.
Both the certificate and the key must be in local storage on the NetScaler appliance before they can be added to the appliance. If your certificate or key file is not on the appliance, upload it to the appliance before you create the pair.
Important: Certificates and keys are stored in the /nsconfig/ssl directory by default. If your certificates or keys are stored in any other location, you must provide the absolute path to the files on the NetScaler appliance. The NetScaler FIPS appliances do not support external keys (non-FIPS keys). On a FIPS appliance, you cannot load keys from a local storage device such as a hard disk or flash memory. The FIPS keys must be present in the Hardware Security Module (HSM) of the appliance.
On a NetScaler MPX appliance and a NetScaler FIPS appliance, only RSA private keys are supported. On a VPX virtual appliance, both RSA and DSA private keys are supported. On an SDX appliance if SSL chips are assigned to an instance, then only RSA private keys are supported. However, if SSL chips are not assigned to an instance, then both RSA and DSA private keys are supported. In all the cases, you can bind a CA certificate with either RSA or DSA keys.

Set the notification period and enable the expiry monitor to issue a prompt before the certificate expires.

The NetScaler appliance supports the following input formats of the certificate and the private-key files:
- PEM - Privacy Enhanced Mail
- DER - Distinguished Encoding Rule
- PFX - Personal Information Exchange

The format is automatically detected by the software. Therefore, you are no longer required to specify the format in the inform parameter. If you do specify the format (correct or incorrect), it is ignored by the software. The format of the certificate and the key file must be the same.
Note: A certificate must be signed by using one of the following hash algorithms:
- MD5
- SHA-1
- SHA-224
- SHA-256
- SHA-384 (supported only on the front end)
- SHA-512 (supported only on the front end)

An MPX appliance supports certificates of 512 or more bits, up to the following sizes:
- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate (includes intermediate and root certificates)
- 4096-bit certificate on the back-end server
- 4096-bit client certificate (if client authentication is enabled on the virtual server)

A VPX virtual appliance supports certificates of 512 or more bits, up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate (includes intermediate and root certificates)
- 2048-bit certificate on the back-end server
- 2048-bit client certificate (if client authentication is enabled on the virtual server)

> **Note**
>
> A NetScaler SDX appliance supports certificates of 512 or more bits. Each NetScaler VPX instance hosted on the appliance supports the certificate sizes listed above for a VPX virtual appliance. However, if an SSL chip is assigned to an instance, that instance supports the certificate sizes supported by an MPX appliance.

At the command prompt, type the following commands to add a certificate-key pair and verify the configuration:

- add ssl certKey <certkeyName> -cert <string>[(-key <string> [-password]) | -fipsKey <string>] [-inform (DER | PEM)] [<passplain>] [-expiryMonitor (ENABLED | DISABLED) [-notificationPeriod <positive_integer>]]
- show ssl certKey [<certkeyName>]

Example

```
> add ssl certKey sslckey -cert server_cert.pem -key server_key.pem -password ssl -expiryMonitor ENABLED -notificationPeriod 30
 Done
Note: For FIPS appliances, replace -key with -fipskey
> show ssl certKey sslckey
      Name: sslckey          Status: Valid,   Days to expiration:8418
      Version: 3
      Serial Number: 01
      Signature Algorithm: md5WithRSAEncryption
      Issuer:  C=US,ST=SJ,L=SJ,O=NS,OU=NSSSL,CN=www.root.com
      Validity
           Not Before: Jul 15 02:25:01 2005 GMT
           Not After : Nov 30 02:25:01 2032 GMT
      Subject:  C=US,ST=SJ,L=SJ,O=NS,OU=NSSSL,CN=www.server.com
      Public Key Algorithm: rsaEncryption
      Public Key size: 2048
 Done
```

To modify the expiry monitor or notification period in a certificate-key pair, use the set ssl certkey command. To replace the certificate or key in a certificate-key pair, use the update ssl certkey command. The update ssl certkey command has an additional parameter for overriding the domain check. For both commands, enter the name of an existing certificate-key pair. To remove an SSL certificate-key pair, use the rm ssl certkey command, which accepts only the <certkeyName> argument.

Navigate to Traffic Management > SSL Files > Certificates, and configure a certificate-key pair.

Binding the Certificate-Key Pair to the SSL-Based Virtual Server

May 23, 2017

An SSL certificate is an integral element of the SSL encryption and decryption process. The certificate is used during an SSL handshake to establish the identity of the SSL server.

The certificate being used for processing SSL transactions must be bound to the virtual server that receives the SSL data. If you have multiple virtual servers receiving SSL data, a valid certificate-key pair must be bound to each of them.

You can use a valid, existing SSL certificate that you have uploaded to the NetScaler appliance. As an alternative for testing purposes, you can create your own SSL certificate on the appliance. Intermediate certificates created by using a FIPS key on the NetScaler cannot be bound to an SSL virtual server.

As a part of the SSL handshake, in the certificate request message during client authentication, the server lists the distinguished names (DNs) of all the certificate authorities (CAs) bound to the server from which it will accept a client certificate. If you do not want the DN name of a specific CA certificate to be sent to the SSL client, set the skipCA flag. This setting indicates that the particular CA certificate's distinguished name should not be sent to the SSL client.

For details on how to create your own certificate, see Managing Certificates.

Note: Citrix recommends that you use only valid SSL certificates that have been issued by a trusted certificate authority.

At the command prompt, type the following commands to bind an SSL certificate-key pair to a virtual server and verify the configuration:

- bind ssl vserver <vServerName> -certkeyName <certificate-KeyPairName> -CA -skipCAName
- show ssl vserver <vServerName>

Example

```
> bind ssl vs vs1 -certkeyName cert2 -CA -skipCAName
Done
> sh ssl vs vs1
Advanced SSL configuration for VServer vs1:
DH: DISABLED
Ephemeral RSA: ENABLED Refresh Count: 0
Session Reuse: ENABLED Timeout: 120 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
ClearText Port: 0
Client Auth: DISABLED
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SNI: DISABLED
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED
```

```
Push Encryption Trigger: Always
Send Close-Notify: YES
1) CertKey Name: cert1 CA Certificate OCSPCheck: Optional CA_Name Sent
2) CertKey Name: cert2 CA Certificate OCSPCheck: Optional CA_Name Skipped
1) Cipher Name: DEFAULT
Description: Predefined Cipher Alias
Done
```

If you try to unbind a certificate-key pair from a virtual server by using the unbind ssl certKey <certkeyName> command, an error message appears because the syntax of the command has changed. At the command prompt, type the following command:

unbind ssl vserver <vServerName> -certkeyName <string>

Example

```
unbind ssl vserver vssl -certkeyName sslckey
```

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open an SSL virtual server and, in Advanced Settings, click SSL Certificate.
3. Bind a server certificate or CA certificate to the virtual server. To add a server certificate as an SNI certificate, select Server Certificate for SNI.

Configuring an SSL Virtual Server for Secure Hosting of Multiple Sites

May 13, 2015

Virtual hosting is used by Web servers to host more than one domain name with the same IP address. The NetScaler supports hosting of multiple secure domains by offloading SSL processing from the Web servers using transparent SSL services or virtual server-based SSL offloading. However, when multiple Web sites are hosted on the same virtual server, the SSL handshake is completed before the expected host name is sent to the virtual server. As a result, the NetScaler cannot determine which certificate to present to the client after a connection is established. This problem is resolved by enabling Server Name Indication (SNI) on the virtual server. SNI is a Transport Layer Security (TLS) extension used by the client to provide the host name during handshake initiation. The NetScaler appliance compares this host name to the common name and, if it does not match, compares it to the subject alternative name (SAN). If the name matches, the appliance presents the corresponding certificate to the client.

A wildcard SSL Certificate helps enable SSL encryption on multiple subdomains if the domains are controlled by the same organization and share the same second-level domain name. For example, a wildcard certificate issued to a sports network using the common name "*.sports.net" can be used to secure domains, such as "login.sports.net" and "help.sports.net" but not "login.ftp.sports.net."

Note: On a NetScaler appliance, only domain name, URL, and email ID DNS entries in the SAN field are compared.
You can bind multiple server certificates to a single SSL virtual server or transparent service using the -SNICert option. These certificates are issued by the virtual server or service if SNI is enabled on the virtual server or service. You can enable SNI at any time.

To bind multiple server certificates to a single SSL virtual server by using the command line interface

At the command prompt, type the following commands to configure SNI and verify the configuration:

- set ssl vserver <vServerName>@ [-SNIEnable (ENABLED | DISABLED)]
- bind ssl vserver <vServerName>@ -certkeyName <string> -SNICert
- show ssl vserver <vServerName>

  To bind multiple server certificates to a transparent service by using the NetScaler command line, replace vserver with service and vservername with servicename in the above commands.

  Note: The SSL service should be created with -clearTextPort 80 option.

Example

```
set ssl vserver v1 -snI ENABLED
bind ssl vserver v1 -certkeyName serverabc -SNICert
sh ssl vserver v1
Advanced SSL configuration for VServer v1:
...
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SNI: ENABLED
```

SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED
1)CertKey Name: servercert Server Certificate
1)CertKey Name: abccert Server Certificate for SNI
2)CertKey Name: xyzcert Server Certificate for SNI
3)CertKey Name: startcert Server Certificate for SNI
1)Cipher Name: DEFAULT
Description: Predefined Cipher Alias
Done

To bind multiple server certificates to a single SSL virtual server or transparent SSL service by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open an SSL virtual server and, in Certificates, click Server Certificate.
3. Add a new certificate or select a certificate from the list, and select Server Certificate for SNI.
4. In Advanced Settings, click SSL Parameters.
5. Select SNI Enable.

Support for SNI on the Back-End Service

May 23, 2017

The NetScaler appliance now supports Server Name Indication (SNI) at the back end. That is, the common name is sent as the server name in the client hello to the back-end server for successful completion of the handshake. In addition to helping meet federal system integrator customer security requirements, this enhancement provides the advantage of using only one port instead of opening hundreds of different IP addresses and ports on a firewall.

Federal system integrator customer security requirements include support for Active Directory Federation Services (ADFS) 3.0 in 2012R2 and WAP servers. This requires supporting SNI at the back end on a NetScaler appliance.

> ## Note
>
> For SNI to work, the server name in the client hello must match the host name configured on the back-end service that is bound to an SSL virtual server. For example, if the host name of a backend server is www.mail.example.com, the SNI-enabled back-end service must be configured with the server name as https://www.mail.example.com, and this host name must match the server name in the client hello.

To configure SNI on the back-end service by using the NetScaler command line

At the command prompt, type:

add service <name> <IP> <serviceType> <port>

add lb vserver <name> <IPAddress> <serviceType> <port>

bind lb vserver <name> <serviceName>

set ssl service <serviceName> -**SNIEnable ENABLED** -**commonName** <string>

Example

COPY

```
add service service_ssl 10.217.193.2 SSL 443

add lb vserver ssl-vs 10.1.1.1 SSL 443

bind lb vserver ssl-vs service_ssl

set ssl service service_ssl -SNIEnable ENABLED –commonName www.example.com
```

To configure SNI on the back-end service by using the NetScaler GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Services**.

2. Select an SSL service, and in **Advanced Settings**, select **SSL Parameters**.
3. Select **SNI Enable**.

Binding a Secure Monitor to an SNI-Enabled Back-End Service

You can also bind secure monitors of type HTTP-ECV or TCP-ECV to the back-end services that support SNI. To do this, the custom header in the monitor must be set to the server name that is sent as the SNI extension in the client hello.

To configure and bind a secure monitor to an SNI-enabled back-end service by using the NetScaler command line

At the command prompt, type:

add lb monitor <monitorName> <type>

set lb monitor <monitorName> <type> -**customHeaders** <string>

bind service <name> -**monitorName** <string>

Example COPY

```
> add monitor https-ecv-mon http-ecv

 Done

> set monitor https-ecv-mon HTTP-ECV -customHeaders "Host: example.com\r\n"

 Done

> bind service ssl_service –monitorName https-ecv
```

To configure and bind a secure monitor to an SNI-enabled back-end service by using the NetScaler GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Monitor**.
2. Add a monitor of type **HTTP-ECV** or **TCP-ECV**, and specify a **Custom Header**.
3. Click **Create**.
4. Navigate to **Traffic Management** > **Load Balancing** > **Services**.
5. Select an SSL service and click **Edit**.
6. In **Monitors**, click **Add Binding**, select the monitor created in step 3, and click **Bind**.

Configuring a DTLS Virtual Server

Nov 08, 2017

> **Note**
>
> DTLS is not supported on a NetScaler FIPS appliance.

The SSL and TLS protocols have traditionally been used to secure streaming traffic. Both of these protocols are based on TCP, which is very slow. In addition, TLS cannot handle lost or reordered packets.

UDP is the preferred protocol for audio and video applications, such as Lync, Skype, iTunes, YouTube, training videos, and flash. However, UDP is not secure or reliable. The DTLS protocol is designed to secure data over UDP and is used for applications such as media streaming, VOIP, and online gaming for communication. In DTLS, each handshake message is assigned a specific sequence number within that handshake. When a peer receives a handshake message, it can quickly determine whether that message is the next one expected. If it is, the peer processes the message. If not, the message is queued for handling after all the previous messages have been received.

You must create a DTLS virtual server and a service of type UDP. By default, a DTLS profile (nsdtls_default_profile) is bound to the virtual server. Optionally, you can create and bind a user-defined DTLS profile to the virtual server.

Note: RC4 ciphers are not supported on a DTLS virtual server.

To create a DTLS configuration by using the command line

At the command prompt, type:

```
add lb vserver <vserver_name> DTLS <IPAddress>  <port>
add service  <service_name>  <IPAddress> UDP 443
bind lb vserver  <vserver_name>  <udp_service_name>
```

The following steps are optional:

```
add dtlsProfile dtls1 -maxretryTime <positive_integer>
set ssl vserver <vserver_name> -dtlsProfileName <dtls_profile_name>
```

To create a DTLS configuration by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Create a virtual server of type DTLS, and bind a UDP service to the virtual server.
3. A default DTLS profile is bound to the DTLS virtual server. To bind a different profile, in SSL Parameters, select a different DTLS profile. To create a new profile, click the plus (+) next to DTLS Profile.

Example

The following example is for an end-to-end DTLS configuration:

```
> enable ns feature SSL LB
> add server s1 10.102.59.190
> add service svc1 s1 UDP 32000
> add lb vserver lb1 DTLS 10.102.59.244 443
> add ssl certKey servercert -cert server_cert.pem -key server_key.pem
> bind ssl vserver lb1 -certkeyname servercert
```

```
> bind lb vserver lb1 svc1

> sh lb vserver lb1
        lb1 (10.102.59.244:443) - DTLS  Type: ADDRESS
        State: UP
        Last state change was at Tue May 20 16:41:27 2014
        Time since last state change: 0 days, 00:01:39.120
        Effective State: UP
        Client Idle Timeout: 120 sec
        Down state flush: ENABLED
        Disable Primary Vserver On Down : DISABLED
        Appflow logging: ENABLED
        No. of Bound Services :  1 (Total)       1 (Active)
        Configured Method: LEASTCONNECTION
        Current Method: Round Robin, Reason: A new service is bound
        Mode: IP
        Persistence: NONE
        L2Conn: OFF
        Skip Persistency: None
        IcmpResponse: PASSIVE
        RHIstate: PASSIVE
        New Service Startup Request Rate: 0 PER_SECOND, Increment Interval: 0
        TD: 0
        Mac mode Retain Vlan: DISABLED
        DBS_LB: DISABLED
        Process Local: DISABLED

        1 bound service:
1) svc1 (10.102.59.190: 32000) - UDP State: UP  Weight: 1
 Done
>
> sh ssl vserver lb1

        Advanced SSL configuration for VServer lb1:
        DH: DISABLED
        Ephemeral RSA: ENABLED         Refresh Count: 0
        Session Reuse: ENABLED         Timeout: 1800 seconds
        Cipher Redirect: DISABLED

        ClearText Port: 0
        Client Auth: DISABLED
        SSL Redirect: DISABLED
        Non FIPS Ciphers: DISABLED
        SNI: DISABLED
        DTLSv1: ENABLED
        Send Close-Notify: YES

        DTLS profile name: nsdtls_default_profile
```

1 bound certificate:

1) CertKey Name: servercert Server Certificate

1 configured cipher:

1) Cipher Name: DEFAULT
Description: Predefined Cipher Alias
Done

> sh dtlsProfile nsdtls_default_profile
1) Name: nsdtls_default_profile
PMTU Discovery: DISABLED
Max Record Size: 1460 bytes
Max Retry Time: 3 sec
Hello Verify Request: DISABLED
Terminate Session: DISABLED
Max Packet Count: 120 bytes
Done

Features not supported by a DTLS virtual server

The following options cannot be enabled on a DTLS virtual server:

- SSLv2
- SSLv3
- TLSv1
- TLSv1.1
- TLSv1.2
- Push encrypt trigger
- SSLv2Redirect
- SSLv2URL
- SNI
- Secure renegotiation

Parameters not used by a DTLS virtual server

The following SSL parameters, even if set, are ignored by a DTLS virtual server:

- Encryption trigger packet count
- PUSH encryption trigger timeout
- SSL quantum size
- Encryption trigger timeout
- Subject/Issuer Name Insertion Format

DTLS Profile

Feb 03, 2015

A DTLS profile with the default settings is automatically bound to a DTLS virtual server. However, you can create a new DTLS profile with specific settings to suit your requirement.

To create a DTLS profile by using the command line

- add ssl dtlsProfile <name>
- show ssl dtlsProfile<name>

Example

```
> add dtlsProfile dtls1 -helloVerifyRequest ENABLED -maxretryTime 4
 Done
> show dtlsProfile dtls1
1)     Name: dtls1
       PMTU Discovery: DISABLED
       Max Record Size: 1460 bytes
       Max Retry Time: 4 sec
       Hello Verify Request: ENABLED
       Terminate Session: DISABLED
       Max Packet Count: 120 bytes

 Done
```

To create a DTLS profile by using the configuration utility

Navigate to System > Profiles > DTLS Profiles and configure a new profile.

Importing SSL Files from Remote Hosts

May 20, 2014

You can now import SSL resources, such as certificates, private keys , CRLs, and DH keys, from remote hosts even if FTP access to these hosts is not available. This is especially helpful in environments where shell access to the remote host is restricted. Default folders are created in /nsconfig/ssl as follows:

- For certificate files: /nsconfig/ssl/certfile
- For private keys: the /nsconfig/ssl/keyfile
- For CRLs: /var/netscaler/ssl/crlfile
- For DH keys: /nsconfig/ssl/dhfile

Imports from both HTTP and HTTPS servers are supported. However, the import fails if the file is on an HTTPS server that requires client certificate authentication for access.

Note: The import command is not stored in the configuration (ns.conf) file, because reimporting the file after a restart might cause an error.

To import a certificate file from a remote host by using the command line

At the command prompt, type:

```
import ssl certFile [<name>] [<src>]
```

Example

```
import ssl certfile my-certfile http://www.example.com/file_1
> show ssl certfile
    Name : my-certfile
    URL : http://www.example.com/file_1
```

To remove a certificate file, use the rm ssl certFile command, which accepts only the <name> argument.

To import a key file from a remote host by using the command line

At the command prompt, type:

```
import ssl keyFile [<name>] [<src>]
```

Example

```
import ssl keyfile my-keyfile http://www.example.com/key_file
> show ssl keyfile
    Name : my-keyfile
    URL : http://www.example.com/key_file
```

To remove a key file, use the rm ssl keyFile command, which accepts only the <name> argument.

To import a CRL file from a remote host by using the command line

At the command prompt, type:

```
import ssl crlFile [<name>] [<src>]
```

Example

```
import ssl crlfile my-crlfile http://www.example.com/crl_file
> show ssl crlfile
    Name : my-crlfile
    URL : http://www.example.com/crl_file
```

To remove a CRL file, use the rm ssl crlFile command, which accepts only the <name> argument.

To import a DH file from a remote host by using the command line

At the command prompt, type:

```
import ssl dhFile [<name>] [<src>]
```

Example

```
import ssl dhfile my-dhfile http://www.example.com/dh_file
> show ssl dhfile
    Name : my-dhfile
    URL : http://www.example.com/dh_file
```

To remove a DH file, use the rm ssl dhFile command, which accepts only the <name> argument.

To import an SSL resource by using the configuration utility

Navigate to Traffic Management > SSL > Imports, and then select the appropriate tab.

SSL Profiles

Oct 23, 2017

> **Note**
>
> Support for cluster is added from release 11.1-54.x.

You can use an SSL profile to specify how a NetScaler ADC processes SSL traffic. The profile is a collection of SSL parameter settings for SSL entities, such as virtual servers, services, and service groups, and offers ease of configuration and flexibility. You are not limited to configuring only one set of global parameters. You can create multiple sets (profiles) of global parameters and assign different sets to different SSL entities. SSL profiles are classified into two categories:

- Front end profiles, containing parameters applicable to the front-end entity. That is, they apply to the entity that receives requests from a client.
- Backend profiles, containing parameters applicable to the back-end entity. That is, they apply to the entity that sends client requests to a server.

Unlike a TCP or HTTP profile, an SSL profile is optional. Therefore, there is no default SSL profile. The same profile can be reused across multiples entities. If an entity does not have a profile attached, the values set at the global level apply. For dynamically learned services, current global values apply.

The following table lists the parameters that are part of each profile.

Front end profile	**Backend profile**
cipherRedirect, cipherURL	denySSLReneg
clearTextPort*	encryptTriggerPktCount
clientAuth, clientCert	nonFipsCiphers
denySSLReneg	pushEncTrigger
dh, dhFile, dhCount	pushEncTriggerTimeout
dropReqWithNoHostHeader	pushFlag
encryptTriggerPktCount	quantumSize
eRSA, eRSACount	serverAuth
insertionEncoding	commonName
nonFipsCiphers	sessReuse, sessTimeout
pushEncTrigger	SNIEnable
pushEncTriggerTimeout	ssl3

Front end profile	Backend profile
pushFlag	sslTriggerTimeout
quantumSize	strictCAChecks
redirectPortRewrite	tls1
sendCloseNotify	
sessReuse, sessTimeout	
SNIEnable	
ssl3	
sslRedirect	
sslTriggerTimeout	
strictCAChecks	
tls1, tls11, tls12	

* The clearTextPort parameter applies only to an SSL virtual server.
An error message appears if you try to set a parameter that is not part of the profile (for example, if you try to set the clientAuth parameter in a backend profile).

Some SSL parameters, such as CRL memory size, OCSP cache size, UndefAction Control, and UndefAction Data, are not part of any of the above profiles, because these parameters are independent of entities.

An SSL profile supports the following operations:

- Add—Creates an SSL profile on the NetScaler ADC. Specify whether the profile is front end or backend. Front end is the default.
- Set—Modifies the settings of an existing profile.
- Unset—Sets the specified parameters to their default values. If you do not specify any parameters, an error message appears. If you unset a profile on an entity, the profile is unbound from the entity.
- Remove—Deletes a profile. A profile that is being used by any entity cannot be deleted. Clearing the configuration deletes all the entities. As a result, the profiles are also deleted.
- Show—Displays all the profiles that are available on the NetScaler ADC . If a profile name is specified, the details of that profile are displayed. If an entity is specified, the profiles associated with that entity are displayed.

To create an SSL profile by using the command line

- To add an SSL profile, type: add ssl profile <name> [-sslProfileType (BackEnd | FrontEnd)]
- To modify an existing profile, type: set ssl profile <name>
- To unset an existing profile, type: unset ssl profile <name> [-dh] [-dhFile] [-dhCount] [-eRSA]…
- To unset an existing profile from an entity, type: unset ssl vserver <vServerName> –sslProfile
- To remove an existing profile, type: rm ssl profile <name>
- To display an existing profile, type: sh ssl profile <name>

Examples

1. Adding a front end (default) profile:

   > add sslprofile p1

   Done

2. Adding a backend profile:

   > add sslprofile p2 -sslprofileType backend -tls1 disabled

   Done

3. Enabling settings on a backend profile:

   > set sslprofile p2 -serverAuth eNABLED

   Done

4. Enabling settings on a frontend profile:

   > set sslprofile p1 -clientauth eNABLED -clientcert optional

   Done

   sh ssl profile p1

   1) Configuration for Front-End SSL profile

      Name: p1

      DH: DISABLED

      Ephemeral RSA: ENABLED Refresh Count: 0

      Session Reuse: ENABLED Timeout: 120 seconds

      Non FIPS Ciphers: DISABLED

      Cipher Redirect: DISABLED

      Client Auth: ENABLED Client Cert Required: Optional

      SSL Redirect: DISABLED

      SNI: DISABLED

      SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.1: DISABLED TLSv1.2: DISABLED

      Push Encryption Trigger: Always

      PUSH encryption trigger timeout: 1 ms

      Send Close-Notify: YES

      Push flag: 0x0 (Auto)

      Deny SSL Renegotiation NO

      SSL quantum size: 8 kB

      Strict CA checks: NO

      Encryption trigger timeout 100 mS

      Encryption trigger packet count: 45

      Subject/Issuer Name Insertion Format: Unicode

      Strict Host Header check for SNI enabled SSL sessions: NO

   Done

5. Settings parameters to their default values:

   > unset sslprofile p1 -clientauth -clientcert

   Done

   > sh ssl profile p1

   1) Configuration for Front-End SSL profile

      Name: p1

      DH: DISABLED

      Ephemeral RSA: ENABLED Refresh Count: 0

      Session Reuse: ENABLED Timeout: 120 seconds

      Non FIPS Ciphers: DISABLED

Cipher Redirect: DISABLED
Client Auth: DISABLED
SSL Redirect: DISABLED
SNI: DISABLED
SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.1: DISABLED TLSv1.2: DISABLED
Push Encryption Trigger: Always
PUSH encryption trigger timeout: 1 ms
Send Close-Notify: YES
Push flag: 0x0 (Auto)
Deny SSL Renegotiation NO
SSL quantum size: 8 kB
Strict CA checks: NO
Encryption trigger timeout 100 mS
Encryption trigger packet count: 45
Subject/Issuer Name Insertion Format: Unicode
Strict Host Header check for SNI enabled SSL sessions: NO
Done

6. Deleting a profile:
   > rm sslprofile p1
   Done
7. Binding a profile to a virtual server:
   > set ssl vserver v1 -sslprofile p3
   Done
8. Unbinding a profile from a virtual server:
   >unset ssl vserver v1 -sslprofile
   Done

To create an SSL profile by using the configuration utility

Navigate to System > Profiles, select the SSL Profiles tab, and create an SSL profile.

Enabling Stricter Control on Client Certificate Validation

Note: This feature is supported from release 10.5 build 57.7 and later.
The NetScaler appliance accepts valid Intermediate-CA certificates if they are issued by a single Root-CA. That is, if only the Root-CA certificate is bound to the virtual server, and any intermediate certificate sent with the client certificate is validated by that Root-CA, the appliance trusts the certificate chain and the handshake is successful.

However, if a client sends a chain of certificates in the handshake, none of the intermediate certificates can be validated by using a CRL or OCSP responder unless that certificate is bound to the SSL virtual server. Therefore, even if one of the intermediate certificates is revoked, the handshake is successful. As part of the handshake, the SSL virtual server sends the list of CA certificates that are bound to it. For stricter control, you can configure the SSL virtual server to accept only a certificate that is signed by one of the CA certificates bound to that virtual server. To do so, you must enable the ClientAuthUseBoundCAChain setting in the SSL profile bound to the virtual server. The handshake fails if the client certificate is not signed by one of the CA certificates bound to the virtual server.

For example, say two client certificates, clientcert1 and clientcert2, are signed by the intermediate certificates Int-CA-A and Int-CA-B, respectively. The intermediate certificates are signed by the root certificate Root-CA. Int-CA-A and Root-CA are bound to the SSL virtual server. In the default case (ClientAuthUseBoundCAChain disabled), both clientcert1 and clientcert2

are accepted. However, if ClientAuthUseBoundCAChain is enabled, only clientcert1 is accepted by the NetScaler appliance

To enable stricter control on client certificate validation by using the command line

At the NetScaler command prompt, type:set ssl profile <name> -ClientAuthUseBoundCAChain Enabled

To enable stricter control on client certificate validation by using the configuration utility

1. Navigate to System > Profiles, select the SSL Profiles tab, and create an SSL profile, or select an existing profile.
2. Select Enable Client Authentication using bound CA Chain.

Enabling Stricter Control on Client Certificate Validation

Jun 19, 2015

The NetScaler appliance accepts valid Intermediate-CA certificates if they are issued by a single Root-CA. That is, if only the Root-CA certificate is bound to the virtual server, and any intermediate certificate sent with the client certificate is validated by that Root-CA, the appliance trusts the certificate chain and the handshake is successful.

However, if a client sends a chain of certificates in the handshake, none of the intermediate certificates can be validated by using a CRL or OCSP responder unless that certificate is bound to the SSL virtual server. Therefore, even if one of the intermediate certificates is revoked, the handshake is successful. As part of the handshake, the SSL virtual server sends the list of CA certificates that are bound to it. For stricter control, you can configure the SSL virtual server to accept only a certificate that is signed by one of the CA certificates bound to that virtual server. To do so, you must enable the ClientAuthUseBoundCAChain setting in the SSL profile bound to the virtual server. The handshake fails if the client certificate is not signed by one of the CA certificates bound to the virtual server.

For example, say two client certificates, clientcert1 and clientcert2, are signed by the intermediate certificates Int-CA-A and Int-CA-B, respectively. The intermediate certificates are signed by the root certificate Root-CA. Int-CA-A and Root-CA are bound to the SSL virtual server. In the default case (ClientAuthUseBoundCAChain disabled), both clientcert1 and clientcert2 are accepted. However, if ClientAuthUseBoundCAChain is enabled, only clientcert1 is accepted by the NetScaler appliance

To enable stricter control on client certificate validation by using the command line

At the NetScaler command prompt, type:

- set ssl profile <name> -ClientAuthUseBoundCAChain Enabled
- set ssl vserver <vServerName> -sslProfile <string>

To enable stricter control on client certificate validation by using the configuration utility

1. Navigate to System > Profiles, select the SSL Profiles tab, and create an SSL profile, or select an existing profile.
2. Select Enable Client Authentication using bound CA Chain.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers, and select an SSL virtual server.
4. In Advanced Settings, select SSL Profiles, and select the profile on which you enabled Enable Client Authentication using bound CA Chain.
5. Click OK, and then click Done.

Graceful Cleanup of SSL Sessions

Dec 16, 2015

Some operations, such as updating a certificate to replace a potentially exposed certificate, using a stronger key (2048-bit instead of 1024-bit), adding or removing a certificate to or from a certificate chain, or changing any of the SSL parameters, should clean the SSL sessions gracefully instead of abruptly terminating the sessions.

From build 64.x, existing SSL connections do not break if you update the SSL certificate, cipher list, or SSL parameters. That is, all existing connections continue using the current settings until the sessions are closed, but all new connections use the new certificate or settings. To clear the sessions immediately after a configuration change, you must disable and reenable each entity.

Important: Connections that are in the middle of a handshake, or sessions that are renegotiating, are terminated. Session reuse is not allowed. Additionally, session multiplexing reuse at the back end is not allowed.

If you change a front-end parameter, such as on an SSL virtual server, only the front end connections are affected. If you change a back-end parameter, such as a parameter on an SSL service or service group, only the back-end connections are affected. Changes such as ciphers and certificates apply to both front-end and back-end connections.

The following configuration commands or changes trigger a graceful session cleanup on all affected SSL entities:

1. set ssl vserver command
2. set ssl service command
3. set ssl servicegroup command
4. set ssl profile command
5. set ssl cipher <cipherGroupName> command
6. Binding, unbinding, and reordering ciphers
7. Binding and unbinding ecccurves
8. Inserting, removing, linking and unlinking a certificate

Enhanced SSL Profiles Infrastructure Overview

Oct 22, 2017

Vulnerabilities in SSLv3 and RC4 implementation have emphasized the need to use the latest ciphers and protocols to negotiate the security settings for a network connection. Implementing any changes to the configuration, such as disabling SSLv3 across thousands of SSL end points, is a cumbersome process. Therefore, settings that were part of the SSL end points configuration have been moved to the SSL profiles, along with the default ciphers. To implement changes in the configuration, including cipher support, you need only modify the profile that is bound to the entities.

The default SSL profiles (default front-end and default back-end) contain all the default ciphers and ECC curves, in addition to the settings that were part of the old profiles. Sample outputs for the default profiles are provided in the appendix. The Enable Default Profile operation automatically binds the default front-end profile to all front-end entities, and the default back-end profile to all back-end entities. You can modify a default profile to suit your deployment. You can also create custom profiles and bind them to SSL entities.

Important

After the upgrade, if you enable the default profiles, you cannot undo the changes. That is, the profiles cannot be disabled. Save the configuration and create a copy of the configuration file (ns.conf) before enabling the profiles. However, if you do not wish to use the features in the default profile, you can continue to use the old SSL profiles. For more information about these profiles, see SSL Profiles.

From 11.1 51.x, in the NetScaler GUI and CLI, a confirmation prompt is added when you enable the default profile so that it is not enabled by mistake.

Command COPY

```
> set ssl parameter -defaultProfile ENABLED

Save your configuration before enabling the Default profile. You cannot undo the changes. Are you sure you want to enable the Default p

Done
```

Note

However, if you are using a script, you can bypass the prompt by adding the following command to your script:

```
> set ssl parameter -defaultProfile ENABLED -force

Done
```

By default, some SSL parameters, called *global parameters*, apply to all the SSL end points. However, if a profile is bound to an SSL end point, the global parameters do not apply. The settings specified in the profile apply instead.

Points to Note

1. A profile can be bound to multiple virtual servers, but a virtual server can have only one profile bound to it.
2. You cannot delete a profile that is bound to a virtual server without first unbinding the profile.
3. A cipher or cipher group can be bound to multiple profiles at different priorities.
4. A profile can have multiple ciphers and cipher groups bound at different priorities.
5. Changes to a cipher group are immediately reflected in all the profiles and in all the virtual servers that one of the profiles is bound to.
6. If a cipher suite is part of a cipher group, you cannot remove the cipher suite from the profile without first editing the cipher group to remove the specific cipher suite.
7. If you do not assign a priority to a cipher suite or cipher group that you attach to a profile, it is assigned the lowest priority within the profile.
8. You can create a custom cipher group (also called a user-defined cipher group) from existing cipher groups and cipher suites. If you create cipher group A and add existing cipher groups X and Y to it, in that order, cipher group Y is assigned at a lower priority than cipher group X. That is, the group that is added first has a higher priority.
9. If a cipher suite is already part of a cipher group that is attached to a profile, and the same cipher suite is part of another cipher group that is also attached to the same profile, the cipher suite is not added again as part of the second cipher group. The cipher suite at the higher priority is in effect when traffic is processed.
10. Cipher groups are not expanded in the profile. As a result, the number of lines in the configuration file (ns.conf) is greatly reduced. For example, if there are a thousand SSL virtual servers to which two cipher groups are bound, and each cipher group contains 15 ciphers, expansion would result in 30*1000 entries related to ciphers in the configuration file. With the new profile, it would have only two entries: one for each cipher group that is bound to a profile.
11. Creating a user defined cipher group from existing ciphers and cipher groups is a copy-paste operation. Any changes in the original group are not reflected in the new group.
12. A user-defined cipher group lists all the profiles that it is a part of.
13. A profile lists all the SSL virtual server, services, and service groups that it is bound to.
14. If the default SSL profile feature is enabled, you must use the profile to set or change any of the attributes of a virtual server, service, service group, or an internal service.

Differences between the Old and the New SSL Profile Infrastructure

Nov 21, 2016

	Old Profile	New Profile
Ciphers and ECC Curves included in the profile	No	Yes
Inserting a cipher or cipher group in the middle of an existing list	Unbind all the ciphers and bind again in the order of the required priority.	Add a cipher and assign it a priority. If a priority is not specified, the cipher is assigned the lowest priority in the list.
Unbinding all the ciphers	> unbind ssl vserver <name> ciphername –ALL	unbind ssl profile –cipherName FlushAllCiphers (Release 11.0 build 64.x or later includes the FlushAllCiphers parameter for unbinding all the ciphers or cipher groups from a profile, because ALL is treated like a cipher group.)
State of SSLv3	n/a	Disabled on the default front-end profile (ns_default_ssl_profile_frontend). Note: Before you enable this profile, SSLv3 is enabled globally. After enabling the profile, SSLv3 is disabled on the front-end default profile.

Enabling the Default Profiles

Apr 27, 2017

Important

Save your configuration before you upgrade the software and enable the default profiles.

From release 11.1 build 51.x, in the NetScaler GUI and CLI, a confirmation prompt appears when you enable the default profile so that it is not enabled by mistake.

Command COPY

```
> set ssl parameter -defaultProfile ENABLED

Save your configuration before enabling the Default profile. You cannot undo the changes. Are you sure you want to enable the Default p

Done
```

Note

However, if you are using a script, you can bypass the prompt by adding the following command to your script:

> **set ssl parameter -defaultProfile ENABLED -force**

Done

Upgrade the software to a build that supports the enhanced profile infrastructure, and then enable the default profiles. You can take one of two approaches depending on your specific deployment. If your deployment has a common SSL configuration across end points, see Use Case 1. If your deployment has a large SSL configuration and the SSL parameters and ciphers are not common among end points, see Use Case 2.

Upgrade the software to a build that supports the enhanced profile infrastructure, and then enable the default profiles. You can take one of two approaches depending on your specific deployment. If your deployment has a common SSL configuration across end points, see Use Case 1. If your deployment has a large SSL configuration and the SSL parameters and ciphers are not common among end points, see Use Case 2.

Note

A single operation (Enable Default Profile or set ssl parameter -defaultProfile ENABLED) enables (binds) both the default front-end

profile and the default back-end profile.

To save the configuration by using the NetScaler command line

At the command prompt, type:

> **save config**

> **shell**

root@ns# **cd /nsconfig**

root@ns# **cp ns.conf** ns.conf.NS<currentreleasenumber><currentbuildnumber>

Example COPY

```
> save config

> shell

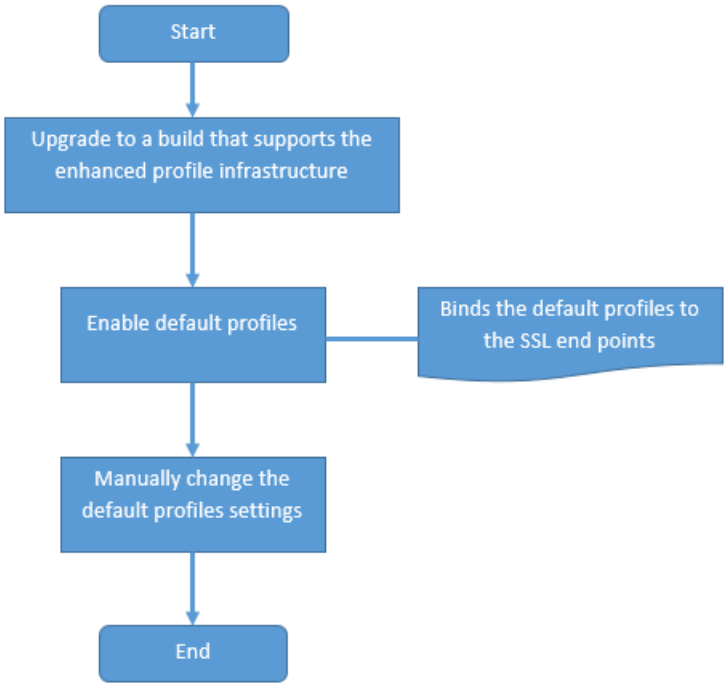
root@ns# cd /nsconfig

root@ns# cp ns.conf ns.conf.NS.12.0.mar.17
```

Use Case 1

After you enable the default profiles, they are bound to all the SSL end points. The default profiles are editable. If your deployment uses most of the default settings and changes only a few parameters, you can edit the default profiles. The changes are immediately reflected across all the end points.

The following flowchart explains the steps that you must perform:



1. For information about upgrading the software, see Upgrading the System Software.

2. Enable the default profiles by using the NetScaler command line or GUI.

- At the command line, type: **set ssl parameter -defaultProfile ENABLED**
- If you prefer to use the GUI, navigate to **Traffic Management** > **SSL** > **Change advanced SSL settings**, scroll down, and select **Enable Default Profile**.

If a profile was not bound to an end point before the upgrade, a default profile is bound to the SSL end point. If a profile was bound to an end point before the upgrade, the same profile is bound after the upgrade, and default ciphers are added to the profile.

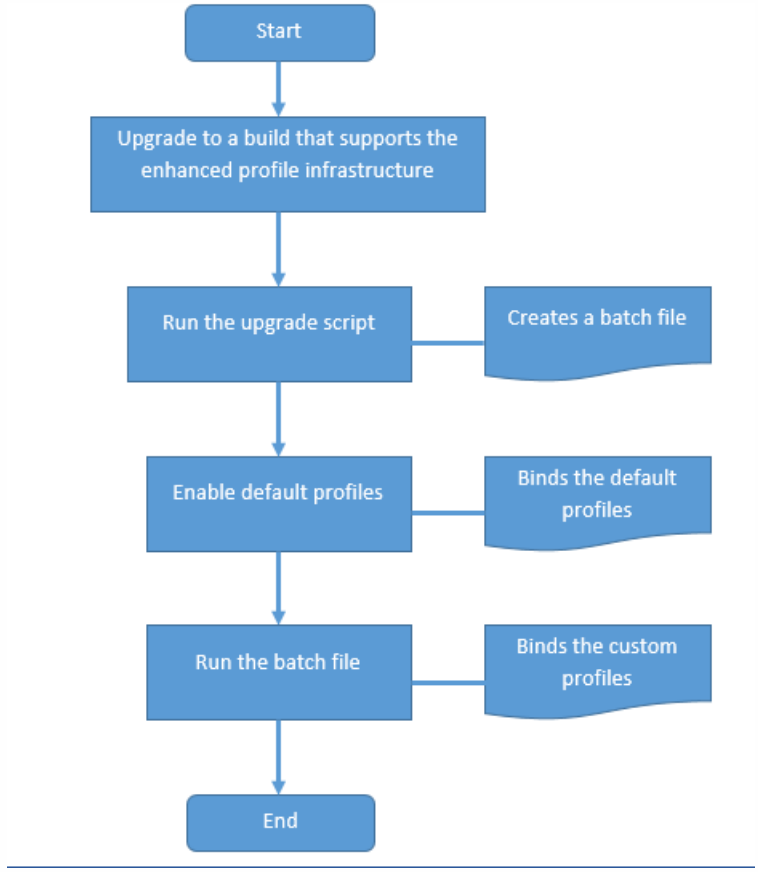
3. (Optional) Manually change any settings in the default profile.

- At the command line, type: **set ssl profile** <name> followed by the parameters to modify.
- If you prefer to use the GUI, navigate to **System** > **Profiles**. In **SSL Profiles**, select a profile and click **Edit**.

Use Case 2

If your deployment uses specific settings for most of the SSL entities, you can run a script that automatically creates custom profiles for each end point and binds them to the end point. Use the procedure detailed in this section to retain the SSL settings for all the SSL end points in your deployment. After upgrading the software, download and run a migration script to capture the SSL-specific changes. The output of running this script is a batch file. Enable the default profiles and then apply the commands in the batch file. See the appendix for a sample migration of the SSL configuration after upgrade.

The following flowchart explains the steps that you must perform:



1. For information about upgrading the software, see Upgrading the System Software.

2. Download and run a script to capture the SSL-specific changes. In addition to other migration activities, the script analyzes the old ns.conf file and moves any special settings (settings other than the default) from an SSL end point configuration to a custom profile. You must enable the default profiles after the upgrade for the configuration changes to apply.

To download the script, log on to https://www.citrix.com/. On the **Downloads** tab, select **NetScaler ADC**, and then select the release (for example, Release 12.0). Within the release, in **Firmware**, select a build (for example, 41.16). The SSL Default Profile Script is available in **Additional Components**.

Note

When running the migration script, you can choose to automatically generate the profile names, or you can prompt the user for the profile names interactively. The migration script checks the following and creates profiles accordingly.

- End points with the default settings and similar ciphers and cipher group settings: The script creates one profile.
- End points with the default settings and with different cipher groups or different priorities for the ciphers/cipher groups: In each case, the script creates a user-defined cipher group, binds it to a profile, and binds each profile to the appropriate end points.
- End points with the default settings and default ciphers: A default profile is bound to the end point.

To run the script, at the command prompt, type:

./default_profile_script /nsconfig/ns.conf -b > <output file name>

> **Note**
>
> You must run this command from the folder in which you store the script.

3. Enable the default profiles by using the NetScaler command line or GUI.

- At the command line, type: **set ssl parameter -defaultProfile ENABLED**
- If you prefer to use the GUI, navigate to **Traffic Management** > **SSL** > **Change advanced SSL settings**, scroll down, and select **Enable Default Profile**.

If a profile was not bound to an end point before the upgrade, a default profile is bound to the SSL end point. If a profile was bound to an end point before the upgrade, the same profile is bound after the upgrade, and default ciphers are added to the profile.

4. Apply the commands in the text file (output of running the migration script) to the configuration. After you apply the commands in the text file, custom profiles are created for end points for which default parameters and ciphers have been changed, and the custom profiles are automatically bound to the end points.

Loading an Old Configuration

Jun 29, 2016

Enabling the default profiles is not reversible. However, if you decide that your deployment does not require the default profiles, you can load an older configuration that you saved before you enabled the default profiles. The changes are effective after you restart the appliance.

To load an old configuration by using the NetScaler command line

At the command prompt, type:

> **shell**

root@ns# **clear config**

root@ns# **cd /nsconfig**

root@ns# **cp ns.conf.NS.**11.0.jun.16 **ns.conf**

root@ns# **reboot**

Appendix A: Sample Migration of the SSL Configuration after Upgrade

Jun 29, 2016

Sample settings on an SSL virtual server, service, and service group are shown below. On the virtual server, client authentication is ENABLED (default is DISABLED), and the AES cipher group is bound to the virtual server. On the service, server authentication is ENABLED (default is DISABLED), and the AES cipher group is bound to the service. The service group has the default settings.

> **sh ssl vserver v1**

Advanced SSL configuration for VServer v1:

DH: DISABLED

Ephemeral RSA: ENABLED Refresh Count: 0

Session Reuse: ENABLED Timeout: 120 seconds

Cipher Redirect: DISABLED

SSLv2 Redirect: DISABLED

ClearText Port: 0

Client Auth: ENABLED Client Cert Required: Mandatory

SSL Redirect: DISABLED

Non FIPS Ciphers: DISABLED

SNI: DISABLED

SSLv2: DISABLED SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.1: DISABLED TLSv1.2: DISABLED

Push Encryption Trigger: Always

Send Close-Notify: YES

ECC Curve: P_256, P_384, P_224, P_521

1) CertKey Name: mycertkey Server Certificate

1) Cipher Name: AES

Description: Predefined Cipher Alias

Done

> **sh ssl service svc1**

Advanced SSL configuration for Back-end SSL Service svc1:

DH: DISABLED

Ephemeral RSA: DISABLED

Session Reuse: ENABLED Timeout: 300 seconds

Cipher Redirect: DISABLED

SSLv2 Redirect: DISABLED

ClearText Port: 0

Server Auth: ENABLED

SSL Redirect: DISABLED

Non FIPS Ciphers: DISABLED

SNI: DISABLED

SSLv2: DISABLED SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.1: DISABLED TLSv1.2: DISABLED

Send Close-Notify: YES

1) Cipher Name: AES

Description: Predefined Cipher Alias

Done

> **sh ssl serviceGroup**

1) Service Group Name: sg1

Session Reuse: ENABLED Timeout: 300 seconds

Server Auth: DISABLED

Non FIPS Ciphers: DISABLED

SSLv3: ENABLED TLSv1.0: ENABLED

Send Close-Notify: YES

Done

The following procedure migrates the above configuration.

1. Save your configuration.

2. Run the migration script. You can redirect the output to a text file if you use the default names for the profiles. Type:

./default_profile_script /nsconfig/ns.conf -b > ssl_config.txt

Use an editor, such as vi, to view the changes. The output cannot be redirected if you provide the profile names interactively. The output is displayed on the console and you must copy and paste it into a text file to apply it to your configuration after the upgrade.

3. After the upgrade, enable the profile.

- At the command line, type: **set ssl parameter -defaultProfile ENABLED**
- In the GUI, navigate to **Traffic Management** > **SSL** > **Change advanced SSL settings**, scroll down and select **Enable Default Profile**.

The interim output for the three new profiles that are created for the virtual server, service, and service group, respectively, is shown below. The default profiles are bound to the end points until you apply the changes in the text file that was created after running the migration script.

> **sh ssl vserver v1**

Advanced SSL configuration for VServer v1:

Profile Name :ns_default_ssl_profile_frontend

1) CertKey Name: mycertkey Server Certificate

Done

>

> **sh ssl service svc1**

Advanced SSL configuration for Back-end SSL Service svc1:

Profile Name :ns_default_ssl_profile_backend

Done

>

> **sh ssl serviceGroup sg1**

Advanced SSL configuration for Back-end SSL Service Group sg1:

Profile Name :ns_default_ssl_profile_backend

Done

4. You must now apply the configuration in ssl_config.txt to the current configuration, so that your non-default settings are applied after the upgrade.

batch -f /<path to the batch file>/ssl_config.txt

5. After applying the configuration, the output changes as follows:

> **show ssl vserver v1**

Advanced SSL configuration for VServer v1:

Profile Name :profile-002

1) CertKey Name: mycertkey Server Certificate

Done

> **show ssl service svc1**

Advanced SSL configuration for Back-end SSL Service svc1:

Profile Name :profile-001

Done

> **show ssl serviceGroup sg1**

Advanced SSL configuration for Back-end SSL Service Group sg1:

Profile Name :profile-003

Done

> **show ssl profile profile-002**

1) Name: profile-002 (Front-End)

SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.1: DISABLED TLSv1.2: DISABLED

Managing Certificates

Jul 20, 2017

An SSL certificate, which is an integral part of any SSL transaction, is a digital data form (X509) that identifies a company (domain) or an individual. The certificate has a public key component that is visible to any client that wants to initiate a secure transaction with the server. The corresponding private key, which resides securely on the NetScaler appliance, is used to complete asymmetric key (or public key) encryption and decryption.

You can obtain an SSL certificate and key in either of the following ways:

- From an authorized certificate authority (CA), such as VeriSign
- By generating a new SSL certificate and key on the NetScaler appliance

Alternately, you can use an existing SSL certificate on the appliance.

Caution: Citrix recommends that you use certificates obtained from authorized CAs, such as VeriSign, for all your SSL transactions. Certificates generated on the NetScaler appliance should be used for testing purposes only, not in any live deployment.

To manage certificates, see the following sections:

- Obtaining a Certificate from a Certificate Authority
- Importing Existing Certificates and Keys
- Generating a Test Certificate
- Generating a Diffie-Hellman (DH) Key
- Adding a Group of SSL Certificates
- Displaying a Certificate Chain
- Generating a Server Test Certificate
- Achieving Perfect Forward Secrecy With DHE
- Modifying and Monitoring Certificates and Keys
- Using Global Site Certificates
- Converting the Format of SSL Certificates for Import or Export
- Enabling Stricter Control on Client Certificate Validation

Obtaining a Certificate from a Certificate Authority

Apr 17, 2017

A certificate authority (CA) is an entity that issues digital certificates for use in public key cryptography. Certificates issued or signed by a CA are automatically trusted by applications, such as web browsers, that conduct SSL transactions. These applications maintain a list of the CAs that they trust. If the certificate being used for the secure transaction is signed by any of the trusted CAs, the application proceeds with the transaction.

To obtain an SSL certificate from an authorized CA, you must create a private key, use that key to create a certificate signing request (CSR), and submit the CSR to the CA. The only special characters allowed in the file names are underscore and dot.

> **Note**
>
> The NetScaler appliance supports certificates of up to 4096 bits.

Creating a Private Key

The private key is the most important part of a digital certificate. By definition, this key is not to be shared with anyone and should be kept securely on the NetScaler appliance. Any data encrypted with the public key can be decrypted only by using the private key.

The appliance supports two encryption algorithms, RSA and DSA, for creating private keys. You can submit either type of private key to the CA. The certificate that you receive from the CA is valid only with the private key that was used to create the CSR, and the key is required for adding the certificate to the NetScaler.

Caution: Be sure to limit access to your private key. Anyone who has access to your private key can decrypt your SSL data. All SSL certificates and keys are stored in the /nsconfig/ssl folder on the appliance. For added security, you can use the Data Encryption Standard (DES) or triple DES (3DES) algorithm to encrypt the private key stored on the appliance.
Note: The length of the SSL key name allowed includes the length of the absolute path name if the path is included in the key name.

To create an RSA private key by using the command line interface

At the command prompt, type the following command:

create ssl rsakey <keyFile> <bits> [-exponent (3 | F4)] [-keyform (DER | PEM)]

Example

```
> create ssl rsakey Key-RSA-1 2048 -exponent F4 -keyform PEM
```

To create a DSA private key by using the command line interface

At the command prompt, type the following command:

create ssl dsakey <keyfile> <bits> [-keyform (DER | PEM)]

Example

> create ssl dsakey Key-DSA-1 2048 -keyform PEM

To create an RSA private key by using the configuration utility

Navigate to **Traffic Management** > **SSL** > **SSL Files** > **Keys** and, select **Create RSA Key**.

To create an DSA private key by using the configuration utility

Navigate to **Traffic Management** > **SSL** > **SSL files** > **Keys** and, select **Create DSA Key**.

Creating a Certificate Signing Request

The certificate signing request (CSR) is a collection of information, including the domain name, other important company details, and the private key to be used to create the certificate. To avoid generating an invalid certificate, make sure that the details you provide are accurate.

The NetScaler appliance supports creating a CSR signed with the SHA1 digest algorithm by default. In earlier releases, to create a CSR signed with the SHA256 digest algorithm, you had to use OpenSSL.

From release 11.1, the appliance supports creating a CSR signed with the SHA256 digest algorithm. The encryption hash algorithm used in SHA256 makes it stronger than SHA1.

To create a certificate signing request by using the NetScaler command line

At the command prompt, type:

create ssl certreq <reqFile> -**keyFile** <input_filename> | -**fipsKeyName** <string>) [-**keyForm** (**DER** | **PEM**) {-PEMPassPhrase }] -**countryName** <string> -**stateName** <string> -**organizationName** <string> -**organizationUnitName** <string> -**localityName** <string> -**commonName** <string> -**emailAddress** <string> {-challengePassword } -**companyName** <string> -**digestMethod** (**SHA1** | **SHA256**)

Example COPY

```
create ssl certreq priv_csr_sha256 -keyfile priv_2048_2 -keyform PEM -countryName IN -stateName Karnataka -localityName Bangalore
```

To create a certificate signing request by using the NetScaler GUI

Navigate to **Traffic Management** > **SSL** > **SSL Files** > **CSRs** and select **Create Certificate Signing Request (CSR).**

Submitting the CSR to the CA

Most CAs accept certificate submissions by email. The CA will return a valid certificate to the email address from which you submit the CSR.

Importing Existing Certificates and Keys

Feb 13, 2017

If you want to use certificates and keys that you already have on other secure servers or applications in your network, you can export them, and then import them to the NetScaler appliance. You might have to convert exported certificates and keys before you can import them to the NetScaler appliance.

For the details of how to export certificates from secure servers or applications in your network, see the documentation of the server or application from which you want to export.

Note: For installation on the NetScaler appliance, key and certificate names cannot contain spaces or special characters other than those supported by the UNIX file system. Follow the appropriate naming convention when you save the exported key and certificate.
A certificate and private key pair is commonly sent in the PKCS#12 format. The NetScaler supports PEM and DER formats for certificates and keys. To convert PKCS#12 to PEM or DER, or PEM or DER to PKCS#12, see Converting the Format of SSL Certificates for Import or Export.

The NetScaler appliance does not support PEM keys in PKCS#8 format. However, you can convert these keys to a supported format by using the OpenSSL interface, which you can access from the NetScaler command line or the configuration utility. Before you convert the key, you need to verify that the private key is in PKCS#8 format. Keys in PKCS#8 format typically start with the following text:

-----BEGIN ENCRYPTED PRIVATE KEY-----

leuSSZQZKgrgUQ==

-----END ENCRYPTED PRIVATE KEY-----

To open the OpenSSL interface from the command line interface

1. Open an SSH connection to the appliance by using an SSH client, such as PuTTY.
2. Log on to the appliance by using the administrator credentials.
3. At the command prompt, type shell.
4. At the shell prompt type openssl.

To open the ssl interface from the configuration utility

Navigate to Traffic Management > SSL and, in the Tools group, select OpenSSL interface.

To convert a non-supported PKCS#8 key format to an encrypted supported key format by using the OpenSSL interface

At the OpenSSL prompt, type one of the following commands, depending on whether the non-supported key format is of type rsa or dsa:

- rsa- in <PKCS#8 Key Filename> -des3 -out <encrypted Key Filename>
- dsa -in <PKCS#8 Key Filename> -des3 -out <encrypted Key Filename>

To convert a non-supported PKCS#8 key format to an unencrypted key format by using the OpenSSL interface

At the OpenSSL prompt, type the following commands, depending on whether the non-supported key format is of type rsa

or dsa:

- rsa -in <PKCS#8 Key Filename> -out <unencrypted Key Filename>
- dsa -in <PKCS#8 Key Filename> -out <unencrypted Key Filename>

Parameters for converting an unsupported key format to a supported key format

<PKCS#8 Key Filename>

The input file name of the incompatible PKCS#8 private key.

<encrypted Key Filename>

The output file name of the compatible encrypted private key in PEM format.

<unencrypted Key Filename>

The output file name of the compatible unencrypted private key in PEM format.

Generating a Test Certificate

Dec 21, 2015

> **Note**
>
> To generate a server test certificate, see Generating a Server Test Certificate.

The NetScaler appliance has a built in CA tools suite that you can use to create self-signed certificates for testing purposes.

Caution: Because these certificates are signed by the NetScaler itself, not by an actual CA, you should not use them in a production environment. If you attempt to use a self-signed certificate in a production environment, users will receive a "certificate invalid" warning each time the virtual server is accessed.
The NetScaler supports creation of the following types of certificates

- Root-CA certificates
- Intermediate-CA certificates
- End-user certificates
  - server certificates
  - client certificates

Before generating a certificate, create a private key and use that to create a certificate signing request (CSR) on the appliance. Then, instead of sending the CSR out to a CA, use the NetScaler CA Tools to generate a certificate.

For details on how to create a private key and a CSR, see Obtaining a Certificate from a Certificate Authority.

To create a certificate by using a wizard

1. Navigate to Traffic Management > SSL.
2. In the details pane, under Getting Started, select the wizard for the type of certificate that you want to create.
3. Follow the instructions on the screen.

To create a Root-CA certificate by using the command line interface

At the command prompt, type the following command:

create ssl cert <certFile> <reqFile> <certType> [-keyFile <input_filename>] [-keyform (**DER** | **PEM**)] [-days <positive_integer>]

Example

In the following example, csreq1 is the CSR and rsa1 is the private key that was created earlier.

```
> create ssl cert cert1 csreq1 ROOT_CERT -keyFile rsa1 -keyForm PEM -days 365
  Done
```

To create an Intermediate-CA certificate certificate by using the command line interface

At the command prompt, type the following command:

create ssl cert <certFile> <reqFile> <certType> [-keyFile <input_filename>] [-keyform (**DER** | **PEM**)] [-days <positive_integer>] [-certForm (**DER** | **PEM**)] [-CAcert <input_filename>] [-CAcertForm (**DER** | **PEM**)] [-CAkey <input_filename>] [-CAkeyForm (**DER** | **PEM**)] [-CAserial <output_filename>]

Example

In the following example, csr1 is the CSR created earlier. Cert1 and rsakey1 are the certificate and corresponding key of the self-signed (root-CA) certificate, and pvtkey1 is the private key of the intermediate-CA certificate.

```
> create ssl cert certsy csr1 INTM_CERT -CAcert cert1 -CAkey rsakey1 -CAserial 23
Done
> create ssl rsakey pvtkey1 2048 -exponent F4 -keyform PEM
```

To create a Root-CA certificate by using the configuration utility

Navigate to Traffic Management > SSL and, in the Getting Started group, select Root-CA Certificate Wizard, and configure a root CA certificate.

To create an Intermediate-CA certificate certificate by using the configuration utility

Navigate to Traffic Management > SSL and, in the Getting Started group, select Intermediate-CA Certificate Wizard, and configure an intermediate CA certificate.

Creating an End-User Certificate

An end-user certificate can be a client certificate or a server certificate. To create a test end-user certificate, specify the Intermediate CA certificate or the self-signed root-CA certificate.

Note: To create an end-user certificate for production use, specify a trusted CA certificate and send the CSR to a certificate authority (CA).

To create a test end-user certificate by using the command line interface

create ssl cert <certFile> <reqFile> <certType> [-keyFile <input_filename>] [-keyform (DER | PEM)] [-days<positive_integer>] [-certForm (DER | PEM)] [-CAcert <input_filename>] [-CAcertForm (DER | PEM)] [-CAkey<input_filename>] [-CAkeyForm (DER | PEM)] [-CAserial <output_filename>]

Example

If there is no intermediate certificate, use the certificate (cert1) and private key (rsakey1) values of the root-CA certificate in CAcert and CAkey.

```
> create ssl cert cert12 csr1 SRVR_CERT -CAcert cert1 -CAkey rsakey1 -CAserial 23
Done
```

If there is an intermediate certificate, use the certificate (certsy) and private key (pvtkey1) values of the intermediate certificate in CAcert and CAkey.

```
> create ssl cert cert12 csr1 SRVR_CERT -CAcert certsy -CAkey pvtkey1 -CAserial 23
Done
```

Generating a Diffie-Hellman (DH) Key

Dec 21, 2015

The Diffie-Hellman (DH) key exchange is a way for two parties involved in an SSL transaction that have no prior knowledge of each other to agree upon a shared secret over an insecure channel. This secret can then be converted into cryptographic keying material for mainly symmetric key cipher algorithms that require such a key exchange.

This feature is disabled by default and should be specifically configured to support ciphers that use DH as the key exchange algorithm.

> **Note**
>
> Generating a 2048-bit DH key may take a long time (up to 30 minutes).

To generate a DH key by using the command line interface

At the command prompt, type the following command:

create ssl dhparam <dhFile> [<bits>] [-gen (2 | 5)]

Example COPY

```
create ssl dhparam Key-DH-1 512 -gen 2
```

To generate a DH key by using the configuration utility

Navigate to **Traffic Management** > **SSL** and, in the **Tools** group, select **Create Diffie-Hellman (DH) key**, and generate a DH key.

Adding a Group of SSL Certificates

Mar 28, 2017

If the server certificate is issued by an intermediate CA that is not recognized by standard web browsers as a trusted CA, the CA certificate(s) must be sent to the client with the server's own certificate. Otherwise, the browser terminates the SSL session because it fails to authenticate the server certificate.

There are two ways to add the server and intermediate certificates:

- Create a certificate set that contains the chain of certificates.
- Create a chain of certificates manually by adding and linking the certificates individually.

Adding and Linking a Certificate Set

Note: This feature is not supported on the NetScaler FIPS platform and in a cluster setup.
Instead of adding and linking individual certificates, you can now group a server certificate and up to nine intermediate certificates in a single file, and then specify the file's name when adding a certificate-key pair. Before you do so, make sure that the following prerequisites are met.

- The certificates in the file are in the following order:
  - Server certificate (should be the first certificate in the file)
  - Optionally, a server key
  - Intermediate certificate 1 (ic1)
  - Intermediate certificate 2 (ic2)
  - Intermediate certificate 3 (ic3), and so on
    Note: Intermediate certificate files are created for each intermediate certificate with the name "<certificatebundlename>.pem_ic<*n*>" where n is between 1 and 9. For example, bundle.pem_ic1, where bundle is the name of the certificate set and ic1 is the first intermediate certificate in the set.
- Bundle option is selected.
- No more than nine intermediate certificates are present in the file.

The file is parsed and the server certificate, intermediate certificates, and server key (if present) are identified. First, the server certificate and key are added. Then, the intermediate certificates are added, in the order in which they were added to the file, and linked accordingly.

An error is reported if any of the following conditions exist:

- A certificate file for one of the intermediate certificates already exists on the appliance.
- The key is placed before the server certificate in the file.
- An intermediate certificate is placed before the server certificate.
- Intermediate certificates are not in placed in the file in the same order as they are created.
- No certificates are present in the file.
- A certificate is not in the proper PEM format.
- The number of intermediate certificates in the file exceeds nine.

To add a certificate set by using the command line interface

At the command prompt, type the following commands to create a certificate set and verify the configuration:

1. add ssl certKey <certkeyName> -cert <string> -key <string> -bundle (YES | NO)
2. show ssl certKey
3. show ssl certlink

Example

In the following example, the certificate set (bundle.pem) contains the following files:

- server certificate (bundle) linked to bundle_ic1
- First intermediate certificate (bundle_ic1) linked to bundle_ic2
- Second intermediate certificate (bundle_ic2) linked to bundle_ic3
- Third intermediate certificate (bundle_ic3)

```
> add ssl certKey bundle -cert bundle.pem -key bundle.pem -bundle yes

> sh ssl certkey

Done

To add a certificate set by using the configuration utility

1. Navigate to **Traffic Management** > **SSL** > **SSL Files** > **Certificates** and, select **Create Certificate**.
2. Click **Create**.

The software automatically detects if it is a certificate bundle.

Creating a Chain of Certificates

Instead of using a set of certificates (a single file), you can create a chain of certificates. The chain links the server certificate to its issuer (the intermediate CA). For this approach to work, the intermediate CA certificate file must already be installed on the NetScaler appliance, and one of the certificates in the chain must be trusted by the client application. For example, link Cert-Intermediate-A to Cert-Intermediate-B, where Cert-Intermediate-B is linked to Cert-Intermediate-C, which is a certificate trusted by the client application.

Note: The NetScaler supports sending a maximum of 10 certificates in the chain of certificates sent to the client (one server certificate and nine CA certificates).

To create a certificate chain by using the command line interface

At the command prompt, type the following commands to create a certificate chain and verify the configuration. (Repeat the first command for each new link in the chain.)

- link ssl certkey <certKeyName> <linkCertKeyName>
- show ssl certlink

Example

```
> link ssl certkey siteAcertkey CAcertkey
 Done

> show ssl certlink

linked certificate:
     1) Cert Name: siteAcertkey CA Cert Name: CAcertkey
 Done
```

To create a certificate chain by using the configuration utility

1. Navigate to **Traffic Management** > **SSL** > **Certificates** > **Server Certificates**.
2. In the **Action** list, select **Link**, and specify a **CA Certificate Name**.

Displaying a Certificate Chain

Jun 18, 2014

A certificate contains the name of the issuing authority and the subject to whom the certificate is issued. To validate a certificate, you must look at the issuer of that certificate and confirm if you trust the issuer. If you do not trust the issuer, you must see who issued the issuer certificate. Go up the chain till you reach the root CA certificate or an issuer that you trust.

As part of the SSL handshake, when a client requests a certificate, the NetScaler appliance presents a certificate and the chain of issuer certificates that are present on the appliance. An administrator can view the certificate chain for the certificates present on the appliance and install any missing certificates.

To view the certificate chain for the certificates present on the appliance by using the command line

At the command prompt, type:

show ssl certchain <cert_name>

Examples

There are 3 certificates: c1, c2, and c3. Certificate c1 is signed by c2, c2 is signed by c3, and c3 is the root CA certificate. The following examples illustrate the output of the show ssl certchain c1 command in different scenarios.

1. Scenario 1:
   - Certificate c2 is linked to c1, and c3 is linked to c2.
   - Certificate c3 is a root CA certificate.

   If you run the following command, the certificate links up to the root CA certificate are displayed.

   ```
   > show ssl certchain c1
   Certificate chain details of certificate name c1 are:
   1) Certificate name: c2          linked; not a root certificate
   2) Certificate name: c3          linked; root certificate
   Done
   ```
2. Scenario 2:
   - Certificate c2 is linked to c1.
   - Certificate c2 is not a root CA certificate.

   If you run the following command, information that certificate c3 is a root CA certificate but is not linked to c2 is displayed.

   ```
   > show ssl certchain c1
   Certificate chain  details of certificate name c1 are:
   1) Certificate Name: c2          linked; not a root certificate
   2) Certificate Name: c3          not linked; root certificate
   Done
   ```
3. Scenario 3:
   - Certificate c1, c2, and c3 are not linked but are present on the appliance.

   If you run the following command, information about all the certificates starting with the issuer of certificate c1 is displayed and it is specified that the certificates are not linked.

   ```
   > show ssl certchain c1
   Certificate chain details of certificate name c1 are:
   1) Certificate Name: c2          not linked; not a root certificate
   ```

2) Certificate Name: c3 not linked; root certificate

Done

4. Scenario 4:
   - Certificate c2 is linked to c1.
   - Certificate c3 is not present on the appliance.

   If you run the following command, information about the certificate linked to c1 is displayed and you are prompted to add a certificate with the subject name specified in c2. In this case, the user is asked to add the root CA certificate c3.

   > show ssl certchain c1

   Certificate chain details of certificate name c1 are:

   1) Certificate Name: c2 linked; not a root certificate

   2) Certificate Name: /C=IN/ST=ka/O=netscaler/CN=test

      Action: Add a certificate with this subject name.

   Done
5. Scenario 5:
   - A certificate is not linked to certificate c1 and the issuer certificate of c1 is not present on the appliance.

   If you run the following command, you are prompted to add a certificate with the subject name in certificate c1.

   > sh ssl certchain c1

   Certificate chain details of certificate name c1 are:

   1) Certificate Name: /ST=KA/C=IN

      Action: Add a certificate with this subject name.

Generating a Server Test Certificate

Mar 28, 2017

The NetScaler appliance allows you to create a test certificate for server authentication by using a GUI wizard in the configuration utility. A server certificate is used to authenticate and identify a server in an SSL handshake. A server certificate is generally issued by a trusted CA and is sent out by the server to a client who uses it to authenticate the server.

For issuing a server test certificate, the appliance operates as a CA. This certificate can be bound to an SSL virtual server for authentication in an SSL handshake with a client. This certificate is for testing purposes only. It should not be used in a production environment.

You can install the server test certificate on any virtual server that uses the SSL or the SSL_TCP protocol.

To generate a server test certificate by using the configuration utility

1. Navigate to **Traffic Management** > **SSL**.
2. In the details pane, under **Getting Started**, select **Create and Install a Server Test Certificate**.

Achieving Perfect Forward Secrecy With DHE

Jun 24, 2015

Generating the DH key is a CPU-intensive operation. In earlier releases, key generation, on a VPX appliance, took a long time because it was done in the software. In earlier releases, key generation is optimized (as defined by NIST in http://csrc.nist.gov/publications/nistpubs/800-56A/SP800-56A_Revision1_Mar08-2007.pdf) by setting the dhKeyExpSizeLimit parameter. You can set this parameter for an SSL virtual server or an SSL profile and then bind the profile to a virtual server.

Additionally, to maintain perfect forward secrecy, DH count must ideally be zero. With this enhancement, you can generate a DH key for each transaction (minimum DHcount is 0) without a significant drop in performance, because the operation is optimized. Earlier, the minimum DH count allowed was 500. That is, you could not regenerate the key for up to 500 transactions.

To optimize DH key generation on a VPX appliance by using the command line

At the command prompt, type commands 1 and 2, or type command 3:

1. add ssl profile <name> [-sslProfileType (BackEnd | FrontEnd)] [-dhCount <positive_integer>] [-dh (ENABLED | DISABLED) -dhFile <string>] [-dhKeyExpSizeLimit (ENABLED | DISABLED)]
2. set ssl vserver <vServerName> [-sslProfile <string>]
3. set ssl vserver <vServerName> [-dh (ENABLED | DISABLED) -dhFile <string>] [-dhCount <positive_integer>] [-dhKeyExpSizeLimit (ENABLED | DISABLED)]

To optimize DH key generation on a VPX appliance by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select Enable DH Key Expire Size Limit.

Modifying and Monitoring Certificates and Keys

Mar 28, 2017

To avoid downtime when replacing a certificate-key pair, you can update an existing certificate. If you want to replace a certificate with a certificate that was issued to a different domain, you must disable domain checks before updating the certificate.

To receive notifications about certificates due to expire, you can enable the expiry monitor.

Updating an Existing Server Certificate

When you remove or unbind a certificate from a configured SSL virtual server, or an SSL service, the virtual server or service becomes inactive until a new valid certificate is bound to it. To avoid downtime, you can use the update feature to replace a certificate-key pair that is bound to an SSL virtual server or an SSL service, without first unbinding the existing certificate.

To update an existing certificate-key pair by using the command line interface

At the command prompt, type the following commands to update an existing certificate-key pair and verify the configuration:

- update ssl certkey <certkeyName> -cert <string> -key <string>
- show ssl certKey <certkeyName>

Example

```
> update ssl certkey siteAcertkey -cert /nsconfig/ssl/cert.pem
     -key /nsconfig/ssl/pkey.pem
 Done

> show ssl certkey siteAcertkey
Name: siteAcertkey       Status: Valid
     Version: 3
     Serial Number: 02
     Signature Algorithm: md5WithRSAEncryption
     Issuer: /C=US/ST=CA/L=Santa Clara/O=siteA/OU=Tech
     Validity
        Not Before: Nov 11 14:58:18 2001 GMT
        Not After: Aug 7 14:58:18 2004 GMT
     Subject: /C=US/ST-CA/L=San Jose/O=CA/OU=Security
     Public Key Algorithm: rsaEncryption
     Public Key size: 2048
 Done
```

To update an existing certificate-key pair by using the configuration utility

1. Navigate to **Traffic Management** > **SSL** > **Certificates**, and select one of the following:
   - Server Certificates
   - Client Certificates

- CA Certificates

2. In the details pane, select the certificate to update, and click **Update**.

Disabling Domain Checks

When an SSL certificate is replaced on the NetScaler, the domain name mentioned on the new certificate should match the domain name of the certificate being replaced. For example, if you have a certificate issued to abc.com, and you are updating it with a certificate issued to def.com, the certificate update fails.

However, if you want the server that has been hosting a particular domain to now host a new domain, you can disable the domain check before updating its certificate.

To disable the domain check for a certificate by using the command line interface

At the command prompt, type the following commands to disable the domain check and verify the configuration:

- update ssl certKey <certkeyName> -noDomainCheck
- show ssl certKey <certkeyName>

Example

```
> update ssl certKey sv -noDomainCheck
 Done
> show ssl certkey sv
 Name: sv
 Cert Path: /nsconfig/ssl/complete/server/server_rsa_512.pem
 Key Path: /nsconfig/ssl/complete/server/server_rsa_512.ky
 Format: PEM
 Status: Valid,   Days to expiration:9349
 Certificate Expiry Monitor: DISABLED
 Done
```

To disable the domain check for a certificate by using the configuration utility

1. Navigate to **Traffic Management** > **SSL** > **Certificates**, and select one of the following:
   - Server Certificates
   - Client Certificates
   - CA Certificates
2. In the details pane, select the certificate to update, and click **Update**.
3. Select **Update the certificate and key**.
4. Select **No Domain Check**.

Enabling the Expiry Monitor

An SSL certificate is valid for a specific period of time. A typical deployment includes multiple virtual servers that process SSL transactions, and the certificates bound to them can expire at different times. An expiry monitor configured on the NetScaler appliance creates entries in the appliance's syslog and nsaudit logs when a certificate configured on the appliance is due to expire.

If you want to create SNMP alerts for certificate expiration, you must configure them separately.

To enable an expiry monitor for a certificate by using the command line interface

At the command prompt, type the following commands to enable an expiry monitor for a certificate and verify the configuration:

- set ssl certKey <certkeyName> [-expiryMonitor (ENABLED | DISABLED) [-notificationPeriod <positive_integer>]]
- show ssl certKey <certkeyName>

Example

```
> set ssl certKey sv -expiryMonitor ENABLED –notificationPeriod 60
 Done

> show ssl certkey sv
Name: sv
 Cert Path: /nsconfig/ssl/complete/server/server_rsa_512.pem
 Key Path: /nsconfig/ssl/complete/server/server_rsa_512.ky
 Format: PEM
 Status: Valid,   Days to expiration:9349
 Certificate Expiry Monitor: ENABLED
 Expiry Notification period: 60 days
 Done
```

To enable an expiry monitor for a certificate by using the configuration utility

1. Navigate to **Traffic Management** > **SSL** > **Certificates**, and select one of the following:
   - Server Certificates
   - Client Certificates
   - CA Certificates
2. In the details pane, select the certificate to update, and click **Update**.
3. Select **Notify When Expires**, and optionally specify a notification period.

Using Global Site Certificates

Feb 13, 2017

A global site certificate is a special-purpose server certificate whose key length is greater than 128 bits. A global site certificate consists of a server certificate and an accompanying intermediate-CA certificate. You must import the global site certificate and its key from the server to the NetScaler appliance.

How Global Site Certificates Work

Export versions of browsers use 40-bit encryption to initiate connections to SSL Web-servers. The server responds to connection requests by sending its certificate. The client and server then decide on an encryption strength based on the server certificate type:

- If the server certificate is a normal certificate and not a global site certificate, the export client and server complete the SSL handshake and uses 40-bit encryption for data transfer.
- If the server certificate is a global site certificate (and if the export client feature is supported by the browser), the export client automatically upgrades to 128-bit encryption for data transfer.

If the server certificate is a global site certificate, the server sends its certificate, along with the accompanying intermediate-CA certificate. The browser first validates the intermediate-CA certificate by using one of the Root-CA certificates that are normally included in web browsers. Upon successful validation of the intermediate-CA certificate, the browser uses the intermediate-CA certificate to validate the server certificate. Once the server is successfully validated, the browser renegotiates (upgrades) the SSL connection to 128-bit encryption.

With Microsoft's Server Gated Cryptography (SGC), if the Microsoft IIS server is configured with an SGC certificate, export clients that receive the certificate renegotiate to use128-bit encryption.

Importing a Global Site Certificate

To import a global site certificate, first export the certificate and server key from the Web server. Global site certificates are generally exported in some binary format, therefore, before importing the global site certificate, convert the certificate and key to the PEM format.

To import a global site certificate

1. Using a text editor, copy the server certificate and the accompanying intermediate-CA certificate into two separate files.

   The individual PEM encoded certificate will begin with the header ----- BEGIN CERTIFICATE----- and end with the trailer -----END CERTIFICATE-----.

2. Use an SFTP client to transfer the server certificate, intermediate-CA certificate, and server-key to the NetScaler.
3. Use the following OpenSSL command to identify the server certificate and intermediate-CA certificate from the two separate files.
   Note: You can launch the OpenSSL interface from the configuration utility. In the navigation pane, click SSL. In the details pane, under Tools, click Open SSL interface.

> openssl x509 -in >path of the CA cert file< ﷯text X509v3 Basic Constraints: **CA:TRUE**

X509v3 Key Usage:

Certificate Sign, CRL Sign

Netscape Cert Type:

SSL CA, S/MIME CA

> openssl x509 -in >path of the server certificate file< -text

X509v3 Basic Constraints:

CA:FALSE

Netscape Cert Type:

SSL Server

4. At the FreeBSD shell prompt, enter the following command:

   openssl x509 -in cert.pem -text | more

   Where **cert.pem** is one of the two certificate files.

   Read the **Subject** field in the command output. For example,

   Subject: C=US, ST=Oregon, L=Portland, O=mycompany, Inc., OU=IT, CN=www.mycompany.com
   If the CN field in the Subject matches the domain-name of your Web site, then this is the server certificate and the other certificate is the accompanying intermediate-CA certificate.

5. Use the server certificate and its private key) to create a certificate key pair on the NetScaler. For details on creating a certificate-key pair on the NetScaler, see Adding a Certificate Key Pair.
6. Add the intermediate-CA certificate on the NetScaler. Use the server certificate you created in step 4 to sign this intermediate certificate. For details on creating an Intermediate-CA certificate on the NetScaler, see Generating a Self-Signed Certificate.

Converting the Format of SSL Certificates for Import or Export

Aug 20, 2013

A NetScaler appliance supports the PEM and DER formats for SSL certificates. Other applications, such as client browsers and some external secure servers, require various public key cryptography standard (PKCS) formats. The NetScaler can convert the PKCS#12 format (the personal information exchange syntax standard) to PEM or DER format for importing a certificate to the appliance, and can convert PEM or DER to PKCS#12 for exporting a certificate. For additional security, conversion of a file for import can include encryption of the private key with the DES or DES3 algorithm.

Note: If you use the configuration utility to import a PKCS#12 certificate, and the password contains a dollar sign ($), backquote (`), or escape (\) character, the import may fail. If it does, the ERROR: Invalid password message appears. If you must use a special character in the password, be sure to prefix it with an escape character (\) unless all imports are performed by using the NetScaler command line.

To convert the format of a certificate by using the command line interface

At the command prompt, type the following command:

Convert ssl pkcs12 <outfile> [-import [-pkcs12File <inputFilename>] [-des | -des3] [-export [-certFile <inputFilename>] [-keyFile <inputFilename>]] During the operation, you are prompted to enter an import password or an export password. For an encrypted file, you are also prompted to enter a passphrase.

Example

```
convert ssl pkcs12 Cert-Import-1.pem -import -pkcs12File Cert-Import-1.pfx -des

convert ssl pkcs12 Cert-Client-1.pfx -export -certFile Cert-Client-1 -keyFile Key-Client-1
```

To convert the format of a certificate by using the configuration utility

Navigate to Traffic Management > SSL and, in the Tools group, select Import PKCS#12 or Export PKCS#12.

Enabling Stricter Control on Client Certificate Validation

May 29, 2016

The NetScaler appliance accepts valid Intermediate-CA certificates if they are issued by a single Root-CA. That is, if only the Root-CA certificate is bound to the virtual server, and any intermediate certificate sent with the client certificate is validated by that Root-CA, the appliance trusts the certificate chain and the handshake is successful.

However, if a client sends a chain of certificates in the handshake, none of the intermediate certificates can be validated by using a CRL or OCSP responder unless that certificate is bound to the SSL virtual server. Therefore, even if one of the intermediate certificates is revoked, the handshake is successful. As part of the handshake, the SSL virtual server sends the list of CA certificates that are bound to it. For stricter control, you can configure the SSL virtual server to accept only a certificate that is signed by one of the CA certificates bound to that virtual server. To do so, you must enable the ClientAuthUseBoundCAChain setting in the SSL profile bound to the virtual server. The handshake fails if the client certificate is not signed by one of the CA certificates bound to the virtual server.

For example, say two client certificates, clientcert1 and clientcert2, are signed by the intermediate certificates Int-CA-A and Int-CA-B, respectively. The intermediate certificates are signed by the root certificate Root-CA. Int-CA-A and Root-CA are bound to the SSL virtual server. In the default case (ClientAuthUseBoundCAChain disabled), both clientcert1 and clientcert2 are accepted. However, if ClientAuthUseBoundCAChain is enabled, only clientcert1 is accepted by the NetScaler appliance

To enable stricter control on client certificate validation by using the command line

At the NetScaler command prompt, type:

set ssl profile <name> -ClientAuthUseBoundCAChain Enabled

To enable stricter control on client certificate validation by using the configuration utility

1. Navigate to **System** > **Profiles**, select the **SSL Profiles** tab, and create an SSL profile, or select an existing profile.
2. Select **Enable Client Authentication using bound CA Chain**.

Managing Certificate Revocation Lists

Feb 13, 2017

A certificate issued by a CA typically remains valid until its expiration date. However, in some circumstances, the CA may revoke the issued certificate before the expiration date (for example, when an owner's private key is compromised, a company's or individual's name changes, or the association between the subject and the CA changes).

A Certificate Revocation List (CRL) identifies invalid certificates by serial number and issuer.

Certificate authorities issue CRLs on a regular basis. You can configure the NetScaler appliance to use a CRL to block client requests that present invalid certificates.

If you already have a CRL file from a CA, add that to the NetScaler. You can configure refresh options. You can also configure the NetScaler to sync the CRL file automatically at a specified interval, from either a web location or an LDAP location. The NetScaler supports CRLs in either the PEM or the DER file format. Be sure to specify the file format of the CRL file being added to the NetScaler.

If you have used the NetScaler as a CA to create certificates that are used in SSL deployments, you can also create a CRL to revoke a particular certificate. This feature can be used, for example, to ensure that self-signed certificates that are created on the NetScaler are not used either in a production environment or beyond a particular date.

Note:
By default, CRLs are stored in the /var/netscaler/ssl directory on the NetScaler appliance.

To manage certificate revocation lists, see the following sections:

- Creating a CRL on the NetScaler
- Adding an Existing CRL to the NetScaler
- Configuring CRL Refresh Parameters
- Synchronizing CRLs
- Performing Client Authentication by using a Certificate Revocation List

Creating a CRL on the NetScaler

Updated: 2013-09-04

Since you can use the NetScaler appliance to act as a certificate authority and create self-signed certificates, you can also revoke certificates that you have created and certificates whose CA certificate you own.

The appliance must revoke invalid certificates before creating a CRL for those certificates. The appliance stores the serial numbers of revoked certificates in an index file and updates the file each time it revokes a certificate. The index file is automatically created the first time a certificate is revoked.

To revoke a certificate or create a CRL by using the command line interface

At the command prompt, type the following command:

create ssl crl <CAcertFile> <CAkeyFile> <indexFile> (-revoke <input_filename> | -genCRL <output_filename>)

Example

```
create ssl crl Cert-CA-1 Key-CA-1 File-Index-1 -revoke Invalid-1

create ssl crl Cert-CA-1 Key-CA-1 File-Index-1 -genCRL CRL-1
```

To revoke a certificate or create a CRL by using the configuration utility

1. Navigate to Traffic Management > SSL and, in the Getting Started group, select CRL Management.
2. Enter the certificate details and, in the Choose Operation list, select Revoke Certificate or Generate CRL.

Adding an Existing CRL to the NetScaler

Updated: 2013-09-05

Before you configure the CRL on the NetScaler appliance, make sure that the CRL file is stored locally on the NetScaler. In the case of an HA setup, the CRL file must be present on both NetScaler appliances, and the directory path to the file must be the same on both appliances.

To add a CRL on the NetScaler by using the command line

At the command prompt, type the following commands to add a CRL on the NetScaler and verify the configuration:

- add ssl crl <crlName> <crlPath> [-inform (DER | PEM)]
- show ssl crl [<crlName>]

Example

```
> add ssl crl crl-one /var/netscaler/ssl/CRL-one -inform PEM
 Done
> show ssl crl crl-one
      Name: crl-one   Status: Valid,  Days to expiration: 29
      CRL Path: /var/netscaler/ssl/CRL-one
```

Format: PEM CAcert: samplecertkey
Refresh: DISABLED
Version: 1
Signature Algorithm: sha1WithRSAEncryption
Issuer: C=US,ST=California,L=Santa Clara,O=NetScaler Inc.,OU=SSL Acceleration,CN=www.ns.com/emailAddress=support@netscaler.com
Last_update:Jun 15 10:53:53 2010 GMT
Next_update:Jul 15 10:53:53 2010 GMT

1) Serial Number: 00
Revocation Date:Jun 15 10:51:16 2010 GMT
Done

To add a CRL on the NetScaler by using the configuration utility

Navigate to Traffic Management > SSL > CRL, and add a CRL.

Configuring CRL Refresh Parameters

Updated: 2014-09-29

A CRL is generated and published by a Certificate Authority periodically or, in some cases, immediately after a particular certificate is revoked. Citrix recommends that you update CRLs on the NetScaler appliance regularly, for protection against clients trying to connect with certificates that are not valid.

The NetScaler can refresh CRLs from a web location or an LDAP directory. When you specify refresh parameters and a web location or an LDAP server, the CRL does not have to be present on the local hard disk drive at the time you execute the command. The first refresh stores a copy on the local hard disk drive, in the path specified by the CRL File parameter. The default path for storing the CRL is /var/netscaler/ssl.
Note: In release 10.0 and later, the method for refreshing a CRL is not included by default. You must explicitly specify an HTTP or LDAP method. If you are upgrading from an earlier release to release 10.0 or later, you must add a method and run the command again.

To configure CRL autorefresh by using the command line

At the command prompt, type the following commands to configure CRL auto refresh and verify the configuration the following commands to configure CRL auto refresh and verify the configuration:

- set ssl crl <crlName> [-refresh (ENABLED | DISABLED)] [-CAcert <string>] [-url <URL | -server <ip_addr|ipv6_addr>] [-method HTTP | (LDAP [-baseDN <string>] [-bindDN <string>] [-scope (Base | One)] [-password <string>] [-binary (YES | NO)])] [-port <port>] [-interval <interval>]
- show ssl crl [<crlName>]

Example

Set CRL crl1 -refresh enabled -method ldap -inform DER -CAcert ca1 -server 10.102.192.192 -port 389 -scope base -baseDN "cn=clnt_rsa4_multicert_der,ou=eng,o=ns,c=in" -time 00:01

set ssl crl crl1 -refresh enabled -method http -cacert ca1 -port 80 -time 00:10 -url http://10.102.192.192/crl/ca1.crl

> sh crl

1) Name: crl1 Status: Valid, Days to expiration: 355
CRL Path: /var/netscaler/ssl/crl1
Format: PEM CAcert: ca1
Refresh: ENABLED Method: HTTP
URL: http://10.102.192.192/crl/ca1.crl Port:80
Refresh Time: 00:10
Last Update: Successful, Date:Tue Jul 6 14:38:13 2010
Done

To configure CRL autorefresh using LDAP or HTTP by using the configuration utility

1. Navigate to Traffic Management > SSL > CRL.
2. Open a CRL, and select Enable CRL Auto Refresh.
   Note: If the new CRL has been refreshed in the external repository before its actual update time as specified by the Last Update time field of the CRL, you should immediately refresh the CRL on the NetScaler.
   To view the last update time, select the CRL, and click Details.

Synchronizing CRLs

Updated: 2013-09-03

The NetScaler appliance uses the most recently distributed CRL to prevent clients with revoked certificates from accessing secure resources.

If CRLs are updated often, the NetScaler needs an automated mechanism to fetch the latest CRLs from the repository. You can configure the NetScaler to update CRLs automatically at a specified refresh interval.

The NetScaler maintains an internal list of CRLs that need to be updated at regular intervals. At these specified intervals, the appliance scans the list for CRLs that need to be updated, connects to the remote LDAP server or HTTP server, retrieves the latest CRLs, and then updates the local CRL list with the new CRLs.

Note: If CRL check is set to mandatory when the CA certificate is bound to the virtual server, and the initial CRL refresh fails, all client-authentication connections with the same issuer

as the CRL are rejected as REVOKED until the CRL is successfully refreshed.
You can specify the interval at which the CRL refresh should be carried out. You can also specify the exact time.

To synchronize CRL autorefresh by using the command line interface

At the command prompt, type the following command:

set ssl crl <crlName> [-interval <interval>] [-day <integer>] [-time <HH:MM>]
Example

```
set ssl crl CRL-1 -refresh ENABLE -interval
MONTHLY -days 10 -time 12:00
```

To synchronize CRL refresh by using the configuration utility

1. Navigate to Traffic Management > SSL > CRL.
2. Open a CRL, select enable CRL Auto Refresh, and specify the interval.

Performing Client Authentication by using a Certificate Revocation List

Updated: 2013-09-03

If a certificate revocation list (CRL) is present on a NetScaler appliance, a CRL check is performed regardless of whether performing the CRL check is set to mandatory or optional. The success or failure of a handshake depends on a combination of the following factors:

- Rule for CRL check
- Rule for client certificate check
- State of the CRL configured for the CA certificate

The following table lists the results of the possible combinations for a handshake involving a revoked certificate.

Table 1. Result of a Handshake with a Client Using a Revoked Certificate

Rule for CRL Check	Rule for Client Certificate Check	State of the CRL Configured for the CA certificate	Result of a Handshake with a Revoked Certificate
Optional	Optional	Missing	Success
Optional	Mandatory	Missing	Success
Optional	Mandatory	Present	Failure
Mandatory	Optional	Missing	Success
Mandatory	Mandatory	Missing	Failure
Mandatory	Optional	Present	Success
Mandatory	Mandatory	Present	Failure
Optional/Mandatory	Optional	Expired	Success
Optional/Mandatory	Mandatory	Expired	Failure

Note:

- The CRL check is optional by default. To change from optional to mandatory or vice-versa, you must first unbind the certificate from the SSL virtual server, and then bind it again after changing the option.
- In the output of the sh ssl vserver command, OCSP check: optional implies that a CRL check is also optional. The CRL check settings are displayed in the output of the sh ssl vserver command only if CRL check is set to mandatory. If CRL check is set to optional, the CRL check details do not appear.

To configure CRL check by using the command line interface

At the command prompt, type the following command:
bind ssl vserver <vServerName> -certkeyName <string> [(-CA -crlCheck (Mandatory | Optional))]
Example

```
bind ssl vs v1 -certkeyName ca -CA -crlCheck mandatory
sh ssl vserver
> sh ssl vs v1

Advanced SSL configuration for VServer v1:

DH: DISABLED
Ephemeral RSA: ENABLED Refresh Count: 0
Session Reuse: ENABLED Timeout: 120 seconds
Cipher Redirect: DISABLED
SSLv2 Redirect: DISABLED
ClearText Port: 0
```

Client Auth: ENABLED Client Cert Required: Mandatory
SSL Redirect: DISABLED
Non FIPS Ciphers: DISABLED
SNI: DISABLED
SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED
Push Encryption Trigger: Always
Send Close-Notify: YES

1) CertKey Name: ca CA Certificate CRLCheck: Mandatory CA_Name Sent

1) Cipher Name: DEFAULT
Description: Predefined Cipher Alias
Done

To configure CRL check by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open an SSL virtual server.
2. Click in the Certificates section.
3. Select a certificate and, in the OCSP and CRL Check list, select CRL Mandatory.

Monitoring Certificate Status with OCSP

Jul 07, 2016

Online Certificate Status Protocol (OCSP) is an Internet protocol that is used to determine the status of a client SSL certificate. NetScaler appliances support OCSP as defined in RFC 2560. OCSP offers significant advantages over certificate revocation lists (CRLs) in terms of timely information. Up-to-date revocation status of a client certificate is especially useful in transactions involving large sums of money and high-value stock trades. It also uses fewer system and network resources. NetScaler implementation of OCSP includes request batching and response caching.

To monitor certificate status with OCSP, see the following sections:

- NetScaler Implementation of OCSP
- OCSP Request Batching
- OCSP Response Caching
- Configuring an OCSP Responder

NetScaler Implementation of OCSP

OCSP validation on a NetScaler appliance begins when the appliance receives a client certificate during an SSL handshake. To validate the certificate, the NetScaler creates an OCSP request and forwards it to the OCSP responder. To do so, the NetScaler uses a locally configured URL. The transaction is in a suspended state until the NetScaler evaluates the response from the server and determines whether to allow the transaction or reject it. If the response from the server is delayed beyond the configured time and no other responders are configured, the NetScaler will allow the transaction or display an error, depending on whether the OCSP check was set to optional or mandatory, respectively.

The NetScaler supports batching of OCSP requests and caching of OCSP responses to reduce the load on the OCSP responder and provide faster responses.

OCSP Request Batching

Each time the NetScaler receives a client certificate, it sends a request to the OCSP responder. To help avoid overloading the OCSP responder, the NetScaler can query the status of more than one client certificate in the same request. For this to work efficiently, a timeout needs to be defined so that processing of a single certificate is not inordinately delayed while waiting to form a batch.

OCSP Response Caching

Caching of responses received from the OCSP responder enables faster responses to the clients and reduces the load on the OCSP responder. Upon receiving the revocation status of a client certificate from the OCSP responder, the NetScaler caches the response locally for a predefined length of time. When a client certificate is received during an SSL handshake, the NetScaler first checks its local cache for an entry for this certificate. If an entry is found that is still valid (within the cache timeout limit), it is evaluated and the client certificate is accepted or rejected. If a certificate is not found, the NetScaler sends a request to the OCSP responder and stores the response in its local cache for a configured length of time.

Configuring an OCSP Responder

Configuring OCSP involves adding an OCSP responder, binding the OCSP responder to a certification authority (CA) certificate, and binding the certificate to an SSL virtual server. If you need to bind a different certificate to an OCSP responder that has already been configured, you need to first unbind the responder and then bind the responder to a different certificate.

To add an OCSP responder by using the command line interface

At the command prompt, type the following commands to configure OCSP and verify the configuration:

- add ssl ocspResponder <name> -url <URL> [-cache (ENABLED | DISABLED)[-cacheTimeout <positive_integer>]] [-batchingDepth <positive_integer>][-batchingDelay <positive_integer>] [-resptimeout <positive_integer>] [-responderCert <string> | -trustResponder] [-producedAtTimeSkew <positive_integer>][-signingCert <string>][-useNonce (YES | NO)][-insertClientCert(YES | NO)]
- bind ssl certKey [<certkeyName>] [-ocspResponder <string>] [-priority <positive_integer>]
- bind ssl vserver <vServerName>@ (-certkeyName <string> (CA [-ocspCheck (Mandatory | Optional)]))
- show ssl ocspResponder [<name>]

Example

```
add ssl ocspResponder ocsp_responder1 -url "http:// www.myCA.org:80/ocsp/" -cache ENABLED -cacheTimeout 30 -batchingDepth 8 -batchingDelay 100 -resptimeout 100 -responderCert responder_ce
bind ssl certKey ca_cert -ocspResponder ocsp_responder1 -priority 1
bind ssl vserver vs1 -certkeyName ca_cert -CA -ocspCheck Mandatory

sh ocspResponder ocsp_responder1
1)Name: ocsp_responder1
URL: http://www.myCA.org:80/ocsp/, IP: 192.128.22.22
Caching: Enabled        Timeout: 30 minutes
Batching: 8 Timeout: 100 mS
HTTP Request Timeout: 100mS
Request Signing Certificate: sign_cert
Response Verification: Full, Certificate: responder_cert
ProducedAt Time Skew: 300 s
Nonce Extension: Enabled
 Client Cert Insertion: Enabled
Done

show certkey ca_cert
Name: ca_cert     Status: Valid,   Days to expiration:8907
Version: 3
…
1)  VServer name: vs1      CA Certificate
1)  OCSP Responder name: ocsp_responder1     Priority: 1
Done

sh ssl vs vs1
Advanced SSL configuration for VServer vs1:
```

DH: DISABLED
...
1) CertKey Name: ca_cert CA Certificate OCSPCheck: Mandatory
1) Cipher Name: DEFAULT
Description: Predefined Cipher Alias
Done

To modify an OCSP responder by using the command line interface

You cannot modify the responder name. All other parameters can be changed using the set ssl ocspResponder command.

At the command prompt, type the following commands to set the parameters and verify the configuration:

- set ssl ocspResponder <name> [-url <URL>] [-cache (ENABLED | DISABLED)] [-cacheTimeout <positive_integer>] [-batchingDepth <positive_integer>] [-batchingDelay <positive_integer>] [-resptimeout <positive_integer>] [-responderCert <string> | -trustResponder][-producedAtTimeSkew <positive_integer>][-signingCert <string>] [-useNonce (YES | NO)]
- unbind ssl certKey [<certkeyName>] [-ocspResponder <string>]
- bind ssl certKey [<certkeyName>] [-ocspResponder <string>] [-priority <positive_integer>]
- show ssl ocspResponder [<name>]

To configure an OCSP responder by using the configuration utility

1. Navigate to Traffic Management > SSL > OCSP Responder, and configure an OCSP responder.
2. Navigate to Traffic Management > SSL > Certificates, select a certificate, and in the Action list, select OCSP Bindings. Bind an OCSP responder.
3. Navigate to Traffic Management > Load Balancing > Virtual Servers, open a virtual server, and click in the Certificates section to bind a CA certificate.
4. Optionally, select select OCSP Mandatory.

Providing the Revocation Status of a Server Certificate to a Client

Jan 09, 2017

The NetScaler implementation of CRL and OCSP reports the revocation status of client certificates only. To check the revocation status of a server certificate received during an SSL handshake, a client must send a request to a certificate authority.

For web sites with heavy traffic, many clients receive the same server certificate. If each client sent a query for the revocation status of the server certificate, the certificate authority would be inundated with OCSP requests to check the validity of the certificate.

OCSP Stapling Solution

To avoid unnecessary congestion, the NetScaler appliance now supports OCSP stapling. That is, the appliance can now send the revocation status of a server certificate to a client, at the time of the SSL handshake, after validating the certificate status from an OCSP responder. The revocation status of a server certificate is "stapled" to the response the appliance sends to the client as part of the SSL handshake. To use the OCSP stapling feature, you must enable it on an SSL virtual server and add an OCSP responder on the appliance.

Note

NetScaler appliances support OCSP stapling as defined in RFC 6066.

OCSP stapling is supported only on the front-end of NetScaler appliances.

Important

NetScaler support for OCSP stapling is limited to handshakes using TLS protocol version 1.0 or higher. This feature is not supported in a cluster setup.

OCSP Response Caching of Server Certificates

During the SSL handshake, when a client requests the revocation status of the server certificate, the NetScaler appliance first checks its local cache for an entry for this certificate. If an entry is found and is still valid, it is evaluated, and the server certificate and its status are presented to the client. If a revocation status entry is not found, the appliance sends the certificate to the client without the status, sends a request for the revocation status of the server certificate to the OCSP responder, and stores the response in its local cache until the nextUpdate time of the OCSP response. If the nextUpdate field is not present, the response is cached for the configured length of time.

The revocation status of a server certificate might not be available when a client initially requests a server certificate, for two reasons. Either the appliance sent a request but is still waiting for a response from the OCSP responder, or the server certificate status information on the appliance has expired and the appliance has to send a fresh request to the OCSP responder.

Configuring OCSP Stapling

Configuring OCSP stapling involves enabling the feature and configuring OCSP. To configure OCSP, you must add an OCSP responder, bind the OCSP responder to a CA certificate, and bind the certificate to an SSL virtual server.

Enabling OCSP Stapling

As soon as you enable OCSP stapling, the NetScaler appliance sends a request to the OCSP responder, for the revocation status of the server certificate that is bound to the SSL virtual server. Upon receiving the response, the appliance caches it until the nextUpdate time of the OCSP response. If the nextUpdate field is not present, the response is cached for a user-specified period. This status is sent to the client during the SSL handshake.

To enable OCSP stapling by using the NetScaler command line

At the command prompt, type:

set ssl vserver <name> -**ocspstapling** [**ENABLED** | **DISABLED**]

Example COPY

```
> set ssl vserver vip1 -ocspStapling ENABLED

Done

> sh ssl vserver vip1

 Advanced SSL configuration for VServer vip1:

 DH: DISABLED

 DH Private-Key Exponent Size Limit: DISABLED Ephemeral RSA: ENABLED Refresh Count: 0

 Session Reuse: ENABLED Timeout: 120 seconds

 Cipher Redirect: DISABLED

 SSLv2 Redirect: DISABLED

 ClearText Port: 0

 Client Auth: DISABLED
```

```
SSL Redirect: DISABLED

Non FIPS Ciphers: DISABLED

SNI: ENABLED

OCSP Stapling: ENABLED

SSLv2: DISABLED SSLv3: DISABLED TLSv1.0: ENABLED  TLSv1.1: ENABLED  TLSv1.2: ENABLED

Push Encryption Trigger: Always

Send Close-Notify: YES

ECC Curve: P_256, P_384, P_224, P_521

1) CertKey Name: server_certificate1 Server Certificate

1) Cipher Name: DEFAULT

 Description: Default cipher list with encryption strength >= 128bit

Done
```

To enable OCSP stapling by using the NetScaler GUI

1. Navigate to **Traffic Management** > **SSL** > **Virtual Server**.
2. Open a virtual server and, in **SSL Parameters**, select **OCSP Stapling**.

Configuring OCSP

An OCSP responder can be dynamically added (in the case of an internal responder) on the basis of the OCSP URL in the server certificate, or an OCSP responder can be manually added from the NetScaler CLI or GUI.

> ## Note
>
> A manually added OCSP responder takes precedence over a dynamically added responder.

To dynamically create an internal OCSP responder, the appliance needs the following:

- Certificate of the issuer of the server certificate (usually the CA certificate).
- Certificate-key pair of the server certificate. This certificate must contain the OCSP URL provided by the CA. The URL is used as the name of the dynamically added internal responder.

An internal OCSP responder cannot be removed (deleted) or unbound from the virtual server. To remove an internal OCSP responder, you must remove the issuer or the server certificate.

> ## Note
>
> Batching depth and batching delay parameters do not apply to server certificates.

To configure OCSP by using the command line interface

At the command prompt, type the following commands to configure OCSP and verify the configuration:

- **add ssl certKey** <certkeyName> (**-cert** <string> [**-password**]) [**-key** <string> | **-fipsKey** <string> | **-hsmKey** <string>] [**-inform** <inform>] [**-expiryMonitor** (**ENABLED** | **DISABLED**) [**-notificationPeriod** <positive_integer>]] [**-bundle** (**YES** | **NO**)]
- **add ssl ocspResponder** <name> **-url** <URL> [**-cache** (**ENABLED** | **DISABLED**)[**-cacheTimeout** <positive_integer>]] [**-resptimeout** <positive_integer>] [**-responderCert** <string> | **-trustResponder**] [**-producedAtTimeSkew** <positive_integer>][**-signingCert** <string>][**-useNonce** (**YES** | **NO**)][**-insertClientCert** (**YES** | **NO**)]
- **bind ssl certKey** [<certkeyName>] [**-ocspResponder** <string>] [**-priority** <positive_integer>]
- **show ssl ocspResponder** [<name>]

Example COPY

```
add ssl certkey root_ca1 –cert root_cacert.pem

add ssl ocspResponder ocsp_responder1 -url "http:// www.myCA.org:80/ocsp/" -cache ENABLED -cacheTimeout 30  -resptimeout 100 -r

bind ssl certKey root_ca1 -ocspResponder ocsp_responder1 -priority 1

sh ocspResponder ocsp_responder1
```

```
1)Name: ocsp_responder1

URL: http://www.myCA.org:80/ocsp/, IP: 192.128.22.22

Caching: Enabled        Timeout: 30 minutes

Batching: 8 Timeout: 100 mS

HTTP Request Timeout: 100mS

Request Signing Certificate: sign_cert

Response Verification: Full, Certificate: responder_cert

ProducedAt Time Skew: 300 s

Nonce Extension: Enabled

 Client Cert Insertion: Enabled

Done

show certkey root_ca1

Name: root_ca1     Status: Valid,   Days to expiration:8907

Version: 3

…

1)  OCSP Responder name: ocsp_responder1     Priority: 1

Done
```

To modify OCSP by using the command line interface

You cannot modify the name of an OCSP responder, but you can use the set ssl ocspResponder command to change any of the other parameters.

At the command prompt, type the following commands to set the parameters and verify the configuration:

- **set ssl ocspResponder** <name> [-**url** <URL>] [-**cache** (**ENABLED** | **DISABLED**)] [-**cacheTimeout** <positive_integer>] [-**resptimeout** <positive_integer>] [-**responderCert** <string> | -**trustResponder**][-**producedAtTimeSkew** <positive_integer>][-**signingCert** <string>] [-**useNonce** (**YES** | **NO**)]
- **unbind ssl certKey** [<certkeyName>] [-**ocspResponder** <string>]
- **bind ssl certKey** [<certkeyName>] [-**ocspResponder** <string>] [-**priority** <positive_integer>]
- **show ssl ocspResponder** [<name>]

To configure OCSP by using the configuration utility

1. Navigate to **Traffic Management** > **SSL** > **OCSP Responder**, and configure an OCSP responder.
2. Navigate to **Traffic Management** > **SSL** > **Certificates**, select a certificate, and in the **Action** list, select **OCSP Bindings**. **Bind an OCSP responder**.
3. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, open a virtual server, and click in the Certificates section to bind a CA certificate.
4. Optionally, select select **OCSP Mandatory**.

Configuring Client Authentication

Feb 13, 2017

In a typical SSL transaction, the client that is connecting to a server over a secure connection checks the validity of the server by checking the server's certificate before initiating the SSL transaction. In some cases, however, you might want to configure the server to authenticate the client that is connecting to it.

With client authentication enabled on an SSL virtual server, the NetScaler appliance asks for the client certificate during the SSL handshake. The appliance checks the certificate presented by the client for normal constraints, such as the issuer signature and expiration date.

Note: For the NetScaler to verify issuer signatures, the certificate of the CA that issued the client certificate must be installed on the NetScaler and bound to the virtual server that the client is transacting with.
If the certificate is valid, the NetScaler allows the client to access all secure resources. But if the certificate is invalid, the NetScaler drops the client request during the SSL handshake.

The NetScaler verifies the client certificate by first forming a chain of certificates, starting with the client certificate and ending with the root CA certificate for the client (for example, VeriSign). The root CA certificate may contain one or more intermediate CA certificates (if the client certificate is not directly issued by the root CA).

Before you enable client authentication on the NetScaler, make sure that a valid client certificate is installed on the client. Then, enable client authentication for the virtual server that will handle the transactions. Finally, bind the certificate of the CA that issued the client certificate to the virtual server on the NetScaler.

Note: A NetScaler MPX appliance supports a certificate-key pair size from 512 to 4096 bits. The certificate must be signed by using one of the following hash algorithms:

- MD5
- SHA-1
- SHA-224
- SHA-256
- SHA-384
- SHA-512

On an SDX appliance, if an SSL chip is assigned to a VPX instance, the certificate-key pair size support of an MPX appliance applies. Otherwise, the normal certificate-key pair size support of a VPX instance applies.

A NetScaler virtual appliance (VPX instance) supports certificates of at least 512 bits, up to the following sizes:

- 4096-bit server certificate on the virtual server
- 4096-bit client certificate on the service
- 4096-bit CA certificate
- 2048-bit certificate on the physical server
- 2048-bit client certificate (if client authentication is enabled on the virtual server)

To configure client authentication, see the following sections:

- Providing the Client Certificate
- Enabling Client-Certificate-Based Authentication
- Binding CA Certificates to the Virtual Server

Providing the Client Certificate

Before you configure client authentication, a valid client certificate must installed on the client. A client certificate includes details about the specific client system that will create secure sessions with the NetScaler appliance. Each client certificate is unique and should be used by only one client system.

Whether you obtain the client certificate from a CA, use an existing client certificate, or generate a client certificate on the NetScaler appliance, you must convert the certificate to the correct format. On the NetScaler, certificates are stored in either the PEM or DER format and must be converted to PKCS#12 format before they are installed on the client system. After converting the certificate and transferring it to the client, system, make sure that it is installed on that system and configured for the client application that will be part of the SSL transactions (for example, the web browser).

For instructions on how to convert a certificate from PEM or DER format to PKCS#12 format, see Converting SSL Certificates for Import or Export.

For instructions on how to generate a client certificate, see Generating a Self-Signed Certificate.

Enabling Client-Certificate-Based Authentication

Updated: 2013-08-20

By default, client authentication is disabled on the NetScaler appliance, and all SSL transactions proceed without authenticating the client. You can configure client authentication to be either optional or mandatory as part of the SSL handshake.

If client authentication is optional, the NetScaler requests the client certificate but proceeds with the SSL transaction even if the client presents an invalid certificate. If client authentication is mandatory, the NetScaler terminates the SSL handshake if the SSL client does not provide a valid certificate.

Caution: Citrix recommends that you define proper access control policies before changing client-certificate-based authentication check to optional.
Note: Client authentication is configured for individual SSL virtual servers, not globally.

To enable client-certificate-based authentication by using the command line interface

At the command prompt, type the following commands to enable the client-certificate-based authentication and verify the configuration:

- set ssl vserver <vServerName> [-clientAuth (ENABLED | DISABLED)] [-clientCert (MANDATORY | OPTIONAL)]
- show ssl vserver <vServerName>

Example

```
> set ssl vserver vssl -clientAuth ENABLED -clientCert Mandatory
 Done
> show ssl vserver vssl

    Advanced SSL configuration for VServer vssl:
    DH: DISABLED
    Ephemeral RSA: ENABLED        Refresh Count: 0
```

```
    Session Reuse: ENABLED        Timeout: 120 seconds
    Cipher Redirect: DISABLED
    SSLv2 Redirect: DISABLED
    ClearText Port: 0
    Client Auth: ENABLED    Client Cert Required: Mandatory
    SSL Redirect: DISABLED
    Non FIPS Ciphers: DISABLED
    SSLv2: DISABLED SSLv3: ENABLED  TLSv1: ENABLED

1)    CertKey Name: sslckey   Server Certificate

1)    Policy Name: client_cert_policy  Priority: 0

1)    Cipher Name: DEFAULT
    Description: Predefined Cipher Alias
Done
```

To enable client-certificate-based authentication by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select Client Authentication, and in the Client Certificate list, select Mandatory.

Binding CA Certificates to the Virtual Server

A CA whose certificate is present on the NetScaler appliance must issue the client certificate used for client authentication. You must bind this certificate to the NetScaler virtual server that will carry out client authentication.

You must bind the CA certificate to the SSL virtual server in such a way that the NetScaler can form a complete certificate chain when it verifies the client certificate. Otherwise, certificate chain formation fails and the client is denied access even if its certificate is valid.

You can bind CA certificates to the SSL virtual server in any order. The NetScaler forms the proper order during client certificate verification.

For example, if the client presents a certificate issued by **CA_A**, where **CA_A** is an intermediate CA whose certificate is issued by **CA_B**, whose certificate is in turn issued by a trusted root CA, **Root_CA**, a chain of certificates that contain all three of these certificates must be bound to the virtual server on the NetScaler.

For instructions on binding one or more certificates to the virtual server, see Binding the Certificate-key Pair to the SSL Based Virtual Server.

For instructions on creating a chain of certificates, see Creating a Chain of Certificates.

Customizing the SSL Configuration

Dec 22, 2016

Once your basic SSL configuration is operational, you can customize some of the parameters that are specific to the certificates being used in SSL transactions. You can also enable and disable session reuse and client authentication, and you can configure redirect responses for cipher and SSLv2 protocol mismatches.

You can also customize SSL settings for two NetScaler appliances in a High Availability configuration, and you can synchronize settings, certificates and keys across those appliances.

These settings will depend on your network deployment and the type of clients you expect will connect to your servers.

To customize the SSL configuration, see the following sections:

- Configuring Diffie-Hellman (DH) Parameters
- Configuring Ephemeral RSA
- Configuring Session Reuse
- Support for TLS Session Ticket Extension
- Secure Implementation of Session Tickets
- Configuring Cipher Redirection
- Configuring SSLv2 Redirection
- Configuring SSL Protocol Settings
- Configuring Close-Notify
- Configuring ECDHE Ciphers
- Leveraging Hardware and Software to Improve ECDHE Cipher Performance
- ECDSA Cipher Suites support on MPX and SDX appliances
- Configuring a Common Name on an SSL Service or Service Group for Server Certificate Authentication
- Configuring Advanced SSL Settings
- Synchronizing Configuration Files in a High Availability Setup
- Managing Server Authentication
- Configuring User-Defined Cipher Groups on the NetScaler Appliance

Configuring Diffie-Hellman (DH) Parameters

Dec 21, 2015

If you are using ciphers on the NetScaler that require a DH key exchange to set up the SSL transaction, enable DH key exchange on the NetScaler and configure other settings based on your network.

To list the ciphers for which DH parameters must be set by using the NetScaler command line, type: sh cipher DH.

To list the ciphers for which DH parameters must be set by using the configuration utility, navigate to Traffic Management > SSL > Cipher Groups, and double-click DH.

For details on how to enable DH key exchange, see Generating a Diffie-Hellman (DH) Key.

To configure DH Parameters by using the command line interface

At the command prompt, type the following commands to configure DH parameters and verify the configuration:

- set ssl vserver <vserverName> -dh <Option> -dhCount <RefreshCountValue> -filepath <string>
- show ssl vserver <vServerName>

Example

```
> set ssl vserver vs-server -dh ENABLED  -dhFile /nsconfig/ssl/ns-server.cert -dhCount 1000
 Done
> show ssl vserver vs-server

      Advanced SSL configuration for VServer vs-server:
      DH: ENABLED
      Ephemeral RSA: ENABLED        Refresh Count: 1000
      Session Reuse: ENABLED        Timeout: 120 seconds
      Cipher Redirect: DISABLED
      SSLv2 Redirect: DISABLED
      ClearText Port: 0
      Client Auth: DISABLED
      SSL Redirect: DISABLED
      Non FIPS Ciphers: DISABLED
      SSLv2: DISABLED SSLv3: ENABLED  TLSv1: ENABLED

1)    Cipher Name: DEFAULT
      Description: Predefined Cipher Alias
 Done
```

To configure DH Parameters by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select Enable DH Param, and specify a refresh count and file path.

Configuring Ephemeral RSA

Aug 20, 2013

Ephemeral RSA allows export clients to communicate with the secure server even if the server certificate does not support export clients (1024-bit certificate). If you want to prevent export clients from accessing the secure web object and/or resource, you need to disable ephemeral RSA key exchange.

By default, this feature is enabled on the NetScaler appliance, with the refresh count set to zero (infinite use).

Note:
The ephemeral RSA key is automatically generated when you bind an export cipher to an SSL or TCP-based SSL virtual server or service. When you remove the export cipher, the eRSA key is not deleted but reused at a later date when another export cipher is bound to an SSL or TCP-based SSL virtual server or service. The eRSA key is deleted when the system restarts.

To configure Ephemeral RSA by using the command line interface

At the command prompt, type the following commands to configure ephemeral RSA and verify the configuration:

- set ssl vserver <vServerName> -eRSA (enabled | disabled) -eRSACount <positive_integer>
- show ssl vserver <vServerName>

Example

```
> set ssl vserver vs-server -eRSA ENABLED -eRSACount 1000
 Done
> show ssl vserver vs-server

        Advanced SSL configuration for VServer vs-server:
        DH: DISABLED
        Ephemeral RSA: ENABLED        Refresh Count: 1000
        Session Reuse: ENABLED        Timeout: 120 seconds
        Cipher Redirect: DISABLED
        SSLv2 Redirect: DISABLED
        ClearText Port: 0
        Client Auth: DISABLED
        SSL Redirect: DISABLED
        Non FIPS Ciphers: DISABLED
        SSLv2: DISABLED SSLv3: ENABLED  TLSv1: ENABLED

1)     Cipher Name: DEFAULT
       Description: Predefined Cipher Alias
 Done
```

To configure Ephemeral RSA by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select Enable Ephemereal RSA, and specify a refresh count.

Configuring Session Reuse

Aug 20, 2013

For SSL transactions, establishing the initial SSL handshake requires CPU-intensive public key encryption operations. Most handshake operations are associated with the exchange of the SSL session key (client key exchange message). When a client session is idle for some time and is then resumed, the SSL handshake is typically conducted all over again. With session reuse enabled, session key exchange is avoided for session resumption requests received from the client.

Session reuse is enabled on the NetScaler appliance by default. Enabling this feature reduces server load, improves response time, and increases the number of SSL transactions per second (TPS) that can be supported by the server.

To configure session reuse by using the command line interface

At the command prompt, type the following commands to configure session reuse and verify the configuration:

- set ssl vserver <vServerName> -sessReuse (ENABLED | DISABLED) -sessTimeout <positive_integer>
- show ssl vserver <vServerName>

Example

```
> set ssl vserver vs-ssl -sessreuse enabled -sesstimeout 600
 Done

> show ssl vserver vs-ssl

      Advanced SSL configuration for VServer vs-ssl:
      DH: DISABLED
      Ephemeral RSA: ENABLED        Refresh Count: 1000
      Session Reuse: ENABLED        Timeout: 600 seconds
      Cipher Redirect: DISABLED
      SSLv2 Redirect: DISABLED
      ClearText Port: 0
      Client Auth: DISABLED
      SSL Redirect: DISABLED
      Non FIPS Ciphers: DISABLED
      SSLv2: DISABLED SSLv3: ENABLED  TLSv1: ENABLED

1)    CertKey Name: Auth-Cert-1      Server Certificate

1)    Cipher Name: DEFAULT
      Description: Predefined Cipher Alias
 Done
```

To configure session reuse by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select Enable Session Reuse, and specify a time for which to keep the session active.

Support for TLS Session Ticket Extension

Feb 13, 2017

> **Note**
>
> This feature was introduced in release 11.1 build 51.x.

An SSL handshake is a CPU-intensive operation. If session reuse is enabled, the server/client key exchange operation is skipped for existing clients. They are allowed to resume their sessions. This improves the response time and increases the number of SSL transactions per second that a server can support. However, the server must store details of each session state, which consumes memory and is difficult to share among multiple servers if requests are load balanced across servers.

NetScaler appliances support the SessionTicket TLS extension. Use of this extension indicates that the session details are stored on the client instead of on the server. The client must indicate that it supports this mechanism by including the session ticket TLS extension in the client Hello message. For new clients, this extension is empty. The server sends a new session ticket in the NewSessionTicket handshake message. The session ticket is encrypted by using a key-pair known only to the server. If a server cannot issue a new ticket at this time, it completes a regular handshake.

This feature is available only in front-end SSL profiles, and only at the front end of communication in which the NetScaler appliance acts as a server and generates session tickets. To learn more about front-end SSL profiles, see http://docs.citrix.com/en-us/netscaler/11-1/ssl/ssl-profiles1.html.

Limitations

- This feature is not supported on a FIPS platform. Support for cluster is added in release 11.1 build 54.x.
- This feature is supported only with TLS versions 1.1 and 1.2.
- SSL session ID persistency is not supported with session tickets.

To enable TLS session ticket extension by using the NetScaler CLI

At the command prompt, type:

set ssl profile <name> -**sessionTicket** (**ENABLED** | **DISABLED**) [-**sessionTicketLifeTime** <positive_integer>

Arguments

sessionTicket

State of TLS session ticket extension. Use of this extension indicates that the session details are stored on the client instead of on the server, as defined in RFC 5077.

Possible values: ENABLED, DISABLED

Default value: DISABLED

sessionTicketLifeTime

Specify a time, in seconds, after which the session ticket expires and a new SSL handshake must be initiated.

Default value: 300

Minimum value: 0

Maximum value: 172800

Example COPY

```
> add ssl profile profile1 -sessionTicket ENABLED -sessionTicketlifeTime 300

 Done
```

To enable TLS session ticket extension by using the NetScaler GUI

1. Navigate to **System** > **Profiles**. Select **SSL Profiles**.
2. Click **Add** and specify a name for the profile.
3. Select **Session ticket**.
4. Optionally, specify **Session Ticket Lifetime (secs)**.

Secure Implementation of Session Tickets

Jan 17, 2018

With TLS session tickets, clients can use abbreviated handshakes for faster reconnection to servers. However, session tickets can pose a security risk if they are not encrypted or not changed for long periods of time. You can secure session tickets by using a symmetric key to encrypt them. Additionally, to achieve forward secrecy, you can specify a time interval at which the session-ticket key is refreshed.

If multiple NetScaler appliances in the same deployment (in a high availability setup, or in a cluster setup) are to decrypt each other's session tickets, you must set (add or load) the same session-ticket key on all the appliances. Session-ticket key data includes the session ticket name, the session AES key used to encrypt or decrypt the ticket, and the session HMAC key used to compute the digest of the ticket.

Session-ticket keys are automatically generated by the appliance. However, the key is different for each appliance. If you need the same key on all the appliances, you must enter the session-ticket key data manually.

> ## Note
>
> If you are entering the session-ticket key data manually, make sure that the configuration across all the NetScaler appliances in an HA setup or in a cluster setup is the same.

In addition to setting the sessionTicketKeyLifeTime parameter to specify how often a session-ticket key is refreshed, you can set the prevSessionTicketKeyLifeTime parameter to specify how long the previous session-ticket key will be maintained for decrypting tickets using that key, after a new key is generated. The prevSessionTicketKeyLifeTime setting extends the time for which a client can use an abbreviated handshake to reconnect. For example, if sessionTicketKeyLifeTime is set to 10 minutes and prevSessionTicketKeyLifeTime to 5 minutes, a new key is generated after 10 minutes and used for all new sessions, but previously connected clients have another 5 minutes for which previously issued tickets will be honored for an abbreviated handshake.

To configure SSL session-ticket data by using the NetScaler command line

At the command prompt, type:

set ssl profile <name> -**sessionTicket ENABLED** -**sessionTicketLifeTime** <positive_integer> -**sessionTicketKeyRefresh** (**ENABLED** | **DISABLED**)] -**sessionTicketKeyLifeTime** <positive_integer> [-**prevSessionTicketKeyLifeTime** <positive_integer>]

Arguments

sessionTicket

Use session tickets as described by RFC 5077. Establishing the initial handshake requires CPU-intensive public key encryption operations. With the ENABLED setting, a server issues a session ticket to a client, which the client can use to perform an abbreviated handshake.

Possible values: ENABLED, DISABLED. Default: DISABLED

sessionTicketLifeTime

Lifetime, in seconds, of the session ticket. After this time expires, clients cannot use this ticket to resume their sessions.

Maximum value: 172800. Minimum value: 0. Default: 300.

sessionTicketKeyRefresh

Regenerate the session-ticket key used to encrypt or decrypt the session tickets when the time specified by the session-ticket key lifetime parameter expires. Automatically enabled if session ticket is enabled. Disabled if the session-ticket data is entered by an administrator.

Possible values: ENABLED, DISABLED. Default: ENABLED

sessionKeyLifeTime

Lifetime, in seconds, of a symmetric key used to encrypt the session tickets issued by a NetScaler appliance.

Maximum value: 86400. Minimum value: 600. Default: 3000

prevSessionKeyLifeTime

Time, in seconds, for which the previous symmetric key used to encrypt session tickets remains valid for existing clients after the session-ticket key lifetime expires. Within this time, existing clients can resume their sessions by using the previous session ticket key. Session tickets for new clients are encrypted by using the new key.

Maximum value: 172800. Minimum value: 0. Default: 0

Example COPY

```
set ssl profile ns_default_ssl_profile_frontend -sessionTicket ENABLED -sessionTicketlifeTime 120 -sessionTicketKeyRefresh ENABLED

Done

show ssl profile ns_default_ssl_profile_frontend

Session Ticket: ENABLED

Session Ticket Lifetime: 120 (secs)

Session Key Auto Refresh: ENABLED

Session Key Lifetime: 100 (secs)

Previous Session Key Lifetime: 60 (secs)
```

To configure SSL session-ticket data by using the NetScaler GUI

1. Navigate to **System** > **Profiles**, and select **SSL Profile**.
2. Select **ns_default_ssl_profile_frontend** and click **Edit**.
3. Edit **Basic Settings** and set the following parameters:
   - Session Ticket
   - Session Ticket Lifetime (secs)
   - Session Ticket Key Auto Refresh
   - Session Ticket Key Lifetime (secs)
   - Previous Session Ticket Key Lifetime (secs)
4. Click **OK**.

To enter SSL session ticket data manually by using the NetScaler command line

At the command prompt, type:

set ssl profile <name> -**sessionTicket ENABLED**

set ssl profile <name> -**sessionTicketKeyData**

show ssl profile ns_default_ssl_profile_frontend

Arguments

sessionTicket

Use of session tickets as described by RFC 5077. Establishing the initial handshake requires CPU-intensive public key encryption operations. With the ENABLED setting, a server issues a session ticket to a client, which the client can use to perform an abbreviated handshake.

Possible values: ENABLED, DISABLED. Default: DISABLED

sessionTicketKeyData

Contains the session ticket name (0-15 bytes), the session AES key used to encrypt or decrypt the session ticket (16-31 bytes), and the session HMAC key used to compute the digest of the ticket (32-47 bytes). Externally generated by an administrator and added to a NetScaler appliance.

Maximum length: 48 bytes

Example COPY

```
set ssl profile ns_default_ssl_profile_frontend -sessionticket ENABLED

Done

set ssl profile ns_default_ssl_profile_frontend -sessionticketkey 1111111111111111111111111111111111111111111111111

Done

show ssl profile ns_default_ssl_profile_frontend

1) Name: ns_default_ssl_profile_frontend (Front-End)

SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.1: ENABLED TLSv1.2: ENABLED

Done
```

To enter SSL session ticket data manually by using the NetScaler GUI

1. Navigate to **System** > **Profiles**, and select **SSL Profile**.
2. Select **ns_default_ssl_profile_frontend** and click **Edit**.
3. Edit **Basic Settings** and set the following parameters
   - Session Ticket
   - Session Ticket Key Data
   - Confirm Session Ticket Key Data
4. Click **OK**.

Configuring Cipher Redirection

Aug 20, 2013

During the SSL handshake, the SSL client (usually a web browser) announces the suite of ciphers that it supports, in the configured order of cipher preference. From that list, the SSL server then selects a cipher that matches its own list of configured ciphers.

If the ciphers announced by the client do not match those configured on the SSL server, the SSL handshake fails, and the failure is announced by a cryptic error message displayed in the browser. These messages rarely mention the exact cause of the error.

With cipher redirection, you can configure an SSL virtual server to deliver accurate, meaningful error messages when an SSL handshake fails. When SSL handshake fails, the NetScaler appliance redirects the user to a previously configured URL or, if no URL is configured, displays an internally generated error page.

To configure cipher redirection by using the command line interface

At the command prompt, type the following commands to configure cipher redirection and verify the configuration:

- set ssl vserver <vServerName> -cipherRedirect < ENABLED | DISABLED> -cipherURL < URL>
- show ssl vserver <vServerName>

Example

```
> set ssl vserver vs-ssl -cipherRedirect ENABLED -cipherURL http://redirectURl
 Done
> show ssl vserver vs-ssl

      Advanced SSL configuration for VServer vs-ssl:
      DH: DISABLED
      Ephemeral RSA: ENABLED        Refresh Count: 1000
      Session Reuse: ENABLED        Timeout: 600 seconds
      Cipher Redirect: ENABLED      Redirect URL: http://redirectURl
      SSLv2 Redirect: DISABLED
      ClearText Port: 0
      Client Auth: DISABLED
      SSL Redirect: DISABLED
      Non FIPS Ciphers: DISABLED
      SSLv2: DISABLED SSLv3: ENABLED  TLSv1: ENABLED

1)    CertKey Name: Auth-Cert-1      Server Certificate

1)    Cipher Name: DEFAULT
      Description: Predefined Cipher Alias
 Done
```

To configure cipher redirection by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.

2. In the SSL Parameters section, select Enable Cipher Redirect, and specify a redirect URL.

Configuring SSLv2 Redirection

Aug 20, 2013

For an SSL transaction to be initiated, and for successful completion of the SSL handshake, the server and the client should agree on an SSL protocol that both of them support. If the SSL protocol version supported by the client is not acceptable to the server, the server does not go ahead with the transaction, and an error message is displayed.

You can configure the server to display a precise error message (user-configured or internally generated) advising the client on the next action to be taken. Configuring the server to display this message requires that you set up SSLv2 redirection.

To configure SSLv2 redirection by using the command line interface

At the command prompt, type the following commands to configure SSLv2 redirection and verify the configuration:

- set ssl vserver <vServerName> [-sslv2Redirect (ENABLED | DISABLED) [-sslv2URL <URL>]]
- show ssl vserver <vServerName>

Example

```
> set ssl vserver vs-ssl -sslv2Redirect ENABLED -sslv2URL http://sslv2URL
 Done
> show ssl vserver vs-ssl

      Advanced SSL configuration for VServer vs-ssl:
      DH: DISABLED
      Ephemeral RSA: ENABLED        Refresh Count: 1000
      Session Reuse: ENABLED        Timeout: 600 seconds
      Cipher Redirect: DISABLED
      SSLv2 Redirect: ENABLED Redirect URL: http://sslv2URL
      ClearText Port: 0
      Client Auth: DISABLED
      SSL Redirect: DISABLED
      Non FIPS Ciphers: DISABLED
      SSLv2: DISABLED SSLv3: ENABLED  TLSv1: ENABLED

1)    CertKey Name: Auth-Cert-1      Server Certificate

1)    Cipher Name: DEFAULT
      Description: Predefined Cipher Alias
 Done
```

To configure SSLv2 redirection by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select SSLv2 Redirect, and specify a URL.

Configuring SSL Protocol Settings

May 20, 2015

The NetScaler appliance supports the SSLv2, SSLv3, TLSv1, TLSv1.1, and TLSv1.2 protocols. Each of these can be set on the appliance as required by your deployment and the type of clients that will connect to the appliance.

TLS protocol versions 1.0, 1.1, and 1.2 are more secure than older versions of the TLS/SSL protocol. However, to support legacy systems, many TLS implementations maintain backward compatibility with the SSLv3 protocol. In an SSL handshake, the highest protocol version common to the client and the SSL virtual server configured on the NetScaler appliance is used.

In the first handshake attempt, a TLS client offers the highest protocol version that it supports. If the handshake fails, the client offers a lower protocol version. For example, if a handshake with TLS version 1.1 is not successful, the client attempts to renegotiate by offering the TLSv1.0 protocol. If that attempt is unsuccessful, the client reattempts with the SSLv3 protocol. A “man in the middle” (MITM) attacker can break the initial handshake and trigger renegotiation with the SSLv3 protocol, and then exploit a vulnerability in SSLv3. To mitigate such attacks, you can disable SSLv3 or not allow renegotiation using a downgraded protocol. However, this might not be practical if your deployment includes legacy systems. An alternative is to recognize a signaling cipher suite value (TLS_FALLBACK_SCSV) in the client request.

A TLS_FALLBACK_SCSV value in a client hello message indicates to the virtual server that the client has previously attempted to connect with a higher protocol version and that the current request is a fallback. If the virtual server detects this value, and it supports a version higher than the one indicated by the client, it rejects the connection with a fatal alert. If a TLS_FALLBACK_SCSV is not included in the client hello message, or if the protocol version in the client hello is the highest protocol version supported by the virtual server, the handshake succeeds.

To configure SSL protocol support by using the command line interface

At the command prompt, type the following commands to configure SSL protocol support and verify the configuration:

- set ssl vserver <vServerName> -ssl2 (ENABLED | DISABLED) -ssl3 (ENABLED | DISABLED) -tls1 (ENABLED | DISABLED) -tls11 (ENABLED | DISABLED) -tls12 (ENABLED | DISABLED)
- show ssl vserver <vServerName>

Example

```
> set ssl vserver vs-ssl -tls11 ENABLED -tls12 ENABLED
 Done
> sh ssl vs vs-ssl

    Advanced SSL configuration for VServer vs-ssl:
    DH: DISABLED
    Ephemeral RSA: ENABLED                Refresh Count: 0
    Session Reuse: ENABLED                Timeout: 120 seconds
    Cipher Redirect: DISABLED
    SSLv2 Redirect: DISABLED
    ClearText Port: 0
    Client Auth: DISABLED
    SSL Redirect: DISABLED
    Non FIPS Ciphers: DISABLED
    SNI: DISABLED
```

```
    SSLv2: DISABLED       SSLv3: ENABLED    TLSv1.0: ENABLED  TLSv1.1: ENABLED  TLSv1.2: ENABLED
    Push Encryption Trigger: Always
    Send Close-Notify: YES

    1 bound certificate:
1)   CertKey Name: mycert  Server Certificate

    1 configured cipher:
1)   Cipher Name: DEFAULT
    Description: Predefined Cipher Alias
Done
```

To configure SSL protocol support by using the configuration Utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select a protocol to enable.

Configuring Close-Notify

Feb 13, 2017

A close-notify is a secure message that indicates the end of SSL data transmission. A close-notify setting is required at the global level. This setting applies to all virtual servers, services, and service groups. For information about the global setting, see Configuring Advanced SSL Settings.

In addition to the global setting, you can set the close-notify parameter at the virtual server, service, or service group level. You therefore have the flexibility of setting the parameter for one entity and unsetting it for another entity. However, make sure that you set this parameter at the global level. Otherwise, the setting at the entity level does not apply.

To configure close-notify at the entity level by using the command line interface

At the command prompt, type any of the following commands to configure close-notify and verify the configuration:

1. To configure close-notify at the virtual server level, type:
   - set ssl vserver <vServerName> -sendCloseNotify (**YES** | **NO**)
   - show ssl vserver <vServerName>
2. To configure close-notify at the service level, type:
   - set ssl service <serviceName> -sendCloseNotify (**YES** | **NO**)
   - show ssl service <serviceName>
3. To configure close-notify at the service group level, type:
   - set ssl serviceGroup <serviceGroupName> -sendCloseNotify (**YES** | **NO**)
   - show ssl serviceGroup <serviceGroupName>

Example

```
> set ssl vserver sslvsvr -sendCloseNotify YES
 Done
```

To configure close-notify at the entity level by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open a virtual server.
2. In the SSL Parameters section, select Send Close-Notify.

Configuring ECDHE Ciphers

Dec 06, 2016

The Citrix NetScaler VPX (only frontend), MPX, SDX, and MPX 9700 series FIPS appliances support the ECDHE cipher group in release 10.5 build 53.9 or later. On an SDX appliance, if an SSL chip is assigned to a VPX instance, the cipher support of an MPX appliance applies. Otherwise, the normal cipher support of a VPX instance applies. For a complete list of ciphers supported by the NetScaler appliance, see Ciphers Supported by the NetScaler Appliance.

For a list of ECDHE ciphers supported on NetScaler appliances, see Cipher/Protocol Support Matrix on the NetScaler Appliance.

ECDHE cipher suites use elliptical curve cryptography (ECC). Because of its smaller key size, ECC is especially useful in a mobile (wireless) environment or an interactive voice response environment, where every millisecond is important. Smaller key sizes save power, memory, bandwidth, and computational cost.

A NetScaler appliance supports the following ECC curves:

- P_256
- P_384
- P_224
- P_521

Note: If you upgrade from a build earlier than release 10.1 build 121.10, you must explicitly bind ECC curves to your existing SSL virtual servers or front end services. The curves are bound by default to any virtual servers or front end services that you create after the upgrade.
You can bind an ECC curve to SSL front-end entities only. By default all four curves are bound, in the following order: P_256, P_384,P_224,P_521. To change the order, you must first unbind all the curves, and then bind them in the desired order.

To unbind ECC curves and bind an ECC curve to an SSL virtual server by using the command line

At the command prompt, type:

- unbind ssl vserver <vServerName> -eccCurveName ALL
- bind ssl vserver <vServerName> -eccCurveName <eccCurveName>

Example

```
unbind ssl vs v1 –eccCurvename ALL
bind ssl vserver  v1 -eccCurveName P_224
> sh ssl vserver v1

 Advanced SSL configuration for VServer v1:
 DH: DISABLED
 Ephemeral RSA: ENABLED  Refresh Count: 0
 Session Reuse: ENABLED  Timeout: 120 seconds
 Cipher Redirect: DISABLED
 SSLv2 Redirect: DISABLED
 ClearText Port: 0
 Client Auth: DISABLED
 SSL Redirect: DISABLED
```

Non FIPS Ciphers: DISABLED
SNI: DISABLED
SSLv2: DISABLED SSLv3: ENABLED TLSv1.0: ENABLED TLSv1.1: DISABLED TLSv1.2: DISABLED
Push Encryption Trigger: Always
Send Close-Notify: YES

ECC Curve: P_224

1) Cipher Name: DEFAULT
Description: Predefined Cipher Alias
Done

Leveraging Hardware and Software to Improve ECDHE Cipher Performance

Dec 21, 2016

> **Note**
>
> This enhancement is applicable only to the following appliances:
>
> - MPX/SDX 11542
> - MPX/SDX 14000
> - MPX 22000, MPX 24000, and MPX 25000 series.

Previously, ECDHE computation on a NetScaler appliance was performed only on the hardware (Cavium chips), which limited the number of SSL sessions at any given time. With this enhancement, some operations are also performed in the software. That is, processing is done both on the Cavium chips and on the CPU cores to improve ECDHE cipher performance.

The processing is first performed in software, up to the configured software crypto threshold. After this threshold is reached, the operations are offloaded to the hardware. Therefore, this hybrid model leverages both hardware and software to improve SSL performance. You can enable the hybrid model by setting the "softwareCryptoThreshold" parameter to suit your requirement. To disable the hybrid model, set this parameter to 0.

Benefits are greatest if the current CPU utilization is not too high, because the CPU threshold is not exclusive to ECDHE computation. For example, if the current workload on the NetScaler appliance consumes 50% of the CPU cycles, and the threshold is set to 80%, ECDHE computation can use an additional 30% of the cycles. After the configured software crypto threshold of 80% is reached, further ECDHE computation is offloaded to the hardware. In that case, actual CPU utilization might exceed 80%, because performing ECDHE computations in hardware consumes some CPU cycles.

To enable the hybrid model by using the NetScaler command line

At the NetScaler command prompt, type:

set ssl parameter -softwareCryptoThreshold <positive_integer>

Synopsis

softwareCryptoThreshold:

NetScaler CPU utilization threshold (as a percentage) beyond which crypto operations are not done in software. A value of zero implies that CPU is not utilized for doing crypto in software.

Default = 0

Min = 0

Max = 100

Example COPY

```
>set ssl parameter - softwareCryptoThreshold 80

Done

>show ssl parameter

Advanced SSL Parameters

SSL quantum size                                : 8 KB

Max CRL memory size                             : 256 MB

Strict CA checks                                : NO

Encryption trigger timeout                      : 100 ms

Send Close-Notify                               : YES

Encryption trigger packet count                 : 45

Deny SSL Renegotiation                          : ALL

Subject/Issuer Name Insertion Format            : Unicode

OCSP cache size                                 : 10 MB

Push flag                                       : 0x0 (Auto)

Strict Host Header check for SNI enabled SSL sessions : NO

PUSH encryption trigger timeout                 : 1 ms

Crypto Device Disable Limit                     : 0

Global undef action for control policies        : CLIENTAUTH

Global undef action for data policies           : NOOP
```

```
Global undef action for data policies          : NOOP

Default profile                                : DISABLED

Disable TLS 1.1/1.2 for SSL_BRIDGE secure monitors    : NO

Disable TLS 1.1/1.2 for dynamic and VPN services      : NO

Software Crypto acceleration CPU Threshold            : 80

Signature and Hash Algorithms supported by TLS1.2     : ALL
```

To enable the hybrid model by using the NetScaler GUI

1. Navigate to **Traffic Management** > **SSL** > **Change advanced SSL settings**.
2. Enter a value for **Software Crypto Threshold (%)**.

ECDSA Cipher Suites support on MPX and SDX appliances

Feb 12, 2018

ECDSA cipher suites use elliptical curve cryptography (ECC). Because of its smaller size, it is particularly helpful in environments where processing power, storage space, bandwidth, and power consumption are constrained.

For the updated content, see https://docs.citrix.com/en-us/netscaler/12/ssl/customize-ssl-config/ecdsa_cipher_suite_support_on_mpx_appliances_with_n3_chips.html.

Important

Starting release 11.1 build 51.x, ECDSA Cipher group support is available on the front end and back end, on MPX and SDX appliances with N3 chips. Use the **show ns hardware** command to find out if your appliance has N3 chips.

Example COPY

```
> sh ns hardware

        Platform: NSMPX-22000 16*CPU+24*IX+12*E1K+2*E1K+4*CVM N3 2200100

        Manufactured on: 8/19/2013

        CPU: 2900MHZ

        Host Id: 1006665862

        Serial no: ENUK6298FT

        Encoded serial no: ENUK6298FT

 Done
```

Configuring a Common Name on an SSL Service or Service Group for Server Certificate Authentication

May 13, 2015

In end-to-end encryption with server authentication enabled, you can include a common name in the configuration of an SSL service or service group. The name that you specify is compared to the common name in the server certificate during an SSL handshake. If the two names match, the handshake is successful. If the common names do not match, the common name specified for the service or service group is compared to values in the subject alternative name (SAN) field in the certificate. If it matches one of those values, the handshake is successful. This configuration is especially useful if there are, for example, two servers behind a firewall and one of the servers spoofs the identity of the other. If the common name is not checked, a certificate presented by either server is accepted if the IP address matches.

Note: Only domain name, URL, and email ID DNS entries in the SAN field are compared.

To configure common-name verification for an SSL service or service group by using the command line interface

At the command prompt, type the following commands to specify server authentication with common-name verification and verify the configuration:

1. To configure common name in a service, type:
   - set ssl service <serviceName> -commonName <string> -serverAuth ENABLED
   - show ssl service <serviceName>
2. To configure common name in a service group, type:
   - set ssl serviceGroup <serviceGroupName> -commonName <string> -serverAuth ENABLED
   - show ssl serviceGroup <serviceGroupName>

Example

```
> set ssl service svc1 -commonName xyz.com -serverAuth ENABLED
 Done
> show ssl service svc1
 Advanced SSL configuration for Back-end SSL Service svc1:
 DH: DISABLED
 Ephemeral RSA: DISABLED
 Session Reuse: ENABLED  Timeout: 300 seconds
 Cipher Redirect: DISABLED
 SSLv2 Redirect: DISABLED
 Server Auth: ENABLED Common Name: www.xyz.com
 SSL Redirect: DISABLED
 Non FIPS Ciphers: DISABLED
 SNI: DISABLED
 SSLv2: DISABLED SSLv3: ENABLED TLSv1: ENABLED

1) CertKey Name: cacert CA Certificate  OCSPCheck: Optional

1) Cipher Name: ALL
 Description: Predefined Cipher Alias
```

Done

To configure common-name verification for an SSL service or service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services or Navigate to Traffic Management > Load Balancing > Service Groups, and open a service or service group.
2. In the SSL Parameters section, select Enable Server Authentication, and specify a common name.

Configuring Advanced SSL Settings

Sep 20, 2013

Advanced customization of your SSL configuration addresses specific issues. You can use the set ssl parameter command or the configuration utility to specify the following:

- Quantum size to be used for SSL transactions.
- CRL memory size.
- OCSP cache size.
- Deny SSL renegotiation.
- Set the PUSH flag for decrypted, encrypted, or all records.
- Drop requests if the client initiates the handshake for one domain and sends an HTTP request for another domain.
- Set the time after which encryption is triggered.
  Note: The time that you specify applies only if you use the set ssl vserver command or the configuration utility to set timer-based encryption.

To configure advanced SSL settings by using the command line interface

At the command prompt, type the following commands to configure advanced SSL settings and verify the configuration:

- set ssl parameter [-quantumSize <quantumSize>] [-crlMemorySizeMB <positive_integer>] [-strictCAChecks (YES | NO)] [-sslTriggerTimeout <positive_integer>] [-sendCloseNotify (YES | NO)] [-encryptTriggerPktCount <positive_integer>] [-denySSLReneg <denySSLReneg>] [-insertionEncoding (Unicode|UTF-8)] [-ocspCacheSize <positive_integer>][- pushFlag <positive_integer>] [- dropReqWithNoHostHeader (YES | NO)] [-pushEncTriggerTimeout <positive_integer>]
- show ssl parameter

Example

```
> set ssl parameter -quantumSize 8 -crlMemorySizeMB 256 -strictCAChecks no -sslt
iggerTimeout 100 -sendClosenotify no -encryptTriggerPktCount 45 -denySSLReneg no
-insertionEncoding unicode -ocspCacheSize 10 -pushFlag 3 -dropReqWithNoHostHeader YES  -pushEncTriggerTimeout 100 ms
 Done

> show ssl parameter
Advanced SSL Parameters
-----------------------
      SSL quantum size:             8 kB
      Max CRL memory size:          256 MB
      Strict CA checks:             NO
      Encryption trigger timeout    100 mS
      Send Close-Notify             NO
      Encryption trigger packet count:      45
      Deny SSL Renegotiation        NO
      Subject/Issuer Name Insertion Format:   Unicode
      OCSP cache size:      10 MB
      Push flag:    0x3 (On every decrypted and encrypted record)
      Strict Host Header check for SNI enabled SSL sessions:        YES
       PUSH encryption trigger timeout 100 ms
 Done
```

To configure advanced SSL settings by using the configuration utility

Navigate to Traffic Management > SSL and, in the Settings group, select Change advanced SSL settings.

PUSH Flag-Based Encryption Trigger Mechanism

The encryption trigger mechanism that is based on the PSH TCP flag now enables you to do the following:

- Merge consecutive packets in which the PSH flag is set into a single SSL record, or ignore the PSH flag.
- Perform timer-based encryption, in which the time-out value is set globally by using the set ssl parameter -pushEncTriggerTimeout <positive_integer> command.

To configure PUSH flag-based encryption by using the command line interface

At the command prompt, type the following commands to configure PUSH flag-based encryption and verify the configuration:

- set ssl vserver <vServerName> [-pushEncTrigger <pushEncTrigger>]
- show ssl vserver

Example

```
Advanced SSL configuration for VServer v1:
        DH: DISABLED
        Ephemeral RSA: ENABLED                  Refresh Count: 0
        Session Reuse: ENABLED                  Timeout: 120 seconds
        Cipher Redirect: DISABLED
        SSLv2 Redirect: DISABLED
        ClearText Port: 0
        Client Auth: DISABLED
        SSL Redirect: DISABLED
        Non FIPS Ciphers: DISABLED
        SNI: DISABLED
        SSLv2: DISABLED         SSLv3: ENABLED          TLSv1: ENABLED
        Push Encryption Trigger: Always
```

To configure PUSH flag-based encryption by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual servers and open an SSL virtual server.
2. In the SSL Parameters section, from the PUSH Encryption Trigger list, select a value.

Synchronizing Configuration Files in a High Availability Setup

Oct 28, 2013

In a high availability (HA) set up, the primary NetScaler appliance in the HA pair automatically synchronizes with the secondary appliance in the pair. In the synchronization process, the secondary copies the primary's /nsconfig/ssl/ directory, which is the default location for storing the certificates and keys for SSL transactions. Synchronization occurs at one-minute intervals and every time a new file is added to the directory.

To synchronize files in a high availability setup by using the command line interface

At the command prompt, type the following command:

sync HA files [<Mode>]

Example

```
sync HA files SSL
```

To synchronize files in a high availability setup by using the configuration utility

Navigate to Traffic Management > SSL and, in the Tools group, select Start SSL certificate, key file synchronization for HA.

Managing Server Authentication

Aug 20, 2013

Since the NetScaler appliance performs SSL offload and acceleration on behalf of a web server, the appliance does not usually authenticate the Web server's certificate. However, you can authenticate the server in deployments that require end-to-end SSL encryption.

In such a situation, the NetScaler becomes the SSL client, carries out a secure transaction with the SSL server, verifies that a CA whose certificate is bound to the SSL service has signed the server certificate, and checks the validity of the server certificate.

To authenticate the server, you must first enable server authentication and then bind the certificate of the CA that signed the server's certificate to the SSL service on the NetScaler. When binding the certificate, you must specify the bind as CA option.

To enable (or disable) server certificate authentication by using the command line interface

At the command prompt, type the following commands to enable server certificate authentication and verify the configuration:

- set ssl service <serviceName> -serverAuth (ENABLED | DISABLED)
- show ssl service <serviceName>

Example

```
> set ssl service ssl-service-1 -serverAuth ENABLED
 Done
> show ssl service ssl-service-1

      Advanced SSL configuration for Back-end SSL Service ssl-service-1:
      DH: DISABLED
      Ephemeral RSA: DISABLED
      Session Reuse: ENABLED        Timeout: 300 seconds
      Cipher Redirect: DISABLED
      SSLv2 Redirect: DISABLED
      Server Auth: ENABLED
      SSL Redirect: DISABLED
      Non FIPS Ciphers: DISABLED
      SSLv2: DISABLED SSLv3: ENABLED  TLSv1: ENABLED

1)    Cipher Name: ALL
      Description: Predefined Cipher Alias
 Done
```

To enable (or disable) server certificate authentication by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Services, and open an SSL service.
2. In the SSL Parameters section, select Enable Server Authentication, and specify a Common Name.
3. In Advanced Settings, select Certificates, and bind a CA certificate to the service.

To bind the CA certificate to the service by using the command line interface

At the command prompt, type the following commands to bind the CA certificate to the service and verify the configuration:

- bind ssl service <serviceName> -certkeyName <string> -CA
- show ssl service <serviceName>

Example

```
> bind ssl service ssl-service-1 -certkeyName samplecertkey -CA
 Done
> show ssl service ssl-service-1

      Advanced SSL configuration for Back-end SSL Service ssl-service-1:
      DH: DISABLED
      Ephemeral RSA: DISABLED
      Session Reuse: ENABLED        Timeout: 300 seconds
      Cipher Redirect: DISABLED
      SSLv2 Redirect: DISABLED
      Server Auth: ENABLED
      SSL Redirect: DISABLED
      Non FIPS Ciphers: DISABLED
      SSLv2: DISABLED SSLv3: ENABLED  TLSv1: ENABLED

1)    CertKey Name: samplecertkey    CA Certificate        CRLCheck: Optional

1)    Cipher Name: ALL
      Description: Predefined Cipher Alias
 Done
```

Configuring User-Defined Cipher Groups on the NetScaler Appliance

Mar 28, 2017

A cipher group is a set of cipher suites that you bind to an SSL virtual server, service, or service group on the NetScaler appliance. A cipher suite comprises a protocol, a key exchange (Kx) algorithm, an authentication (Au) algorithm, an encryption (Enc) algorithm, and a message authentication code (Mac) algorithm. Your appliance ships with a predefined set of cipher groups. When you create a SSL service or SSL service group, the ALL cipher group is automatically bound to it. However, when you create an SSL virtual server or a transparent SSL service, the DEFAULT cipher group is automatically bound to it. In addition, you can create a user-defined cipher group and bind it to an SSL virtual server, service, or service group.

Note: If your MPX appliance does not have any licenses, then only the EXPORT cipher is bound to your SSL virtual server, service, or service group.

To create a user-defined cipher group, first you create a cipher group and then you bind ciphers or cipher groups to this group. If you specify a cipher alias or a cipher group, all the ciphers in the cipher alias or group are added to the user-defined cipher group. You can also add individual ciphers (cipher suites) to a user-defined group. However, you cannot modify a predefined cipher group. Before removing a cipher group, unbind all the cipher suites in the group.

If you bind a cipher group to an SSL virtual server, service, or service group, the ciphers are appended to the existing ciphers that are bound to the entity. To bind a specific cipher group to the entity, you must first unbind the ciphers or cipher group that is bound to the entity and then bind the specific cipher group. For example, to bind only the AES cipher group to an SSL service, you perform the following steps:

1. Unbind the default cipher group ALL that is bound by default to the service when the service is created.
   unbind ssl service <service name> -cipherName ALL

2. Bind the AES cipher group to the service
   bind ssl service <Service name> -cipherName AE

If you want to bind the cipher group DES in addition to AES, at the command prompt, type:

- bind ssl service <service name> -cipherName DES

Note: The free NetScaler virtual appliance supports only the DH cipher group.

To configure a user-defined cipher group by using the command line interface

At the command prompt, type the following commands to add a cipher group, or to add ciphers to a previously created group, and verify the settings:

- add ssl cipher <cipherGroupName>
- bind ssl cipher <cipherGroupName> -cipherName <string>
- show ssl cipher <cipherGroupName>

Example

```
 > add ssl cipher test
 Done
> bind ssl cipher test -cipherName SSLv2
 Done
> show ssl cipher test
```

1) Cipher Name: SSL2-RC2-CBC-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=RC2(128) Mac=MD5
2) Cipher Name: SSL2-RC4-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=RC4(128) Mac=MD5
3) Cipher Name: SSL2-DES-CBC3-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=3DES(168) Mac=MD5
4) Cipher Name: SSL2-DES-CBC-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=DES(56) Mac=MD5
5) Cipher Name: SSL2-RC4-64-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=RC4(64) Mac=MD5
6) Cipher Name: SSL2-EXP-RC4-MD5
Description: SSLv2 Kx=RSA(512) Au=RSA Enc=RC4(40) Mac=MD5 Export
7) Cipher Name: SSL2-EXP-RC2-CBC-MD5
Description: SSLv2 Kx=RSA(512) Au=RSA Enc=RC2(40) Mac=MD5 Export
Done

To unbind ciphers from a cipher group by using the command line interface

At the command prompt, type the following commands to unbind ciphers from a user-defined cipher group, and verify the settings:

- show ssl cipher <cipherGroupName>
- unbind ssl cipher <cipherGroupName> -cipherName <string>
- show ssl cipher <cipherGroupName>

Example

```
> show ssl cipher test
1) Cipher Name: SSL2-RC2-CBC-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=RC2(128) Mac=MD5
2) Cipher Name: SSL2-RC4-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=RC4(128) Mac=MD5
3) Cipher Name: SSL2-DES-CBC3-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=3DES(168) Mac=MD5
4) Cipher Name: SSL2-DES-CBC-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=DES(56) Mac=MD5
5) Cipher Name: SSL2-RC4-64-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=RC4(64) Mac=MD5
6) Cipher Name: SSL2-EXP-RC4-MD5
Description: SSLv2 Kx=RSA(512) Au=RSA Enc=RC4(40) Mac=MD5 Export
7) Cipher Name: SSL2-EXP-RC2-CBC-MD5
Description: SSLv2 Kx=RSA(512) Au=RSA Enc=RC2(40) Mac=MD5 Export
Done

> unbind ssl cipher test -cipherName SSL2-RC2-CBC-MD5

> show ssl cipher test
1) Cipher Name: SSL2-RC4-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=RC4(128) Mac=MD5
2) Cipher Name: SSL2-DES-CBC3-MD5
```

```
Description: SSLv2 Kx=RSA Au=RSA Enc=3DES(168) Mac=MD5
3) Cipher Name: SSL2-DES-CBC-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=DES(56) Mac=MD5
4) Cipher Name: SSL2-RC4-64-MD5
Description: SSLv2 Kx=RSA Au=RSA Enc=RC4(64) Mac=MD5
5) Cipher Name: SSL2-EXP-RC4-MD5
Description: SSLv2 Kx=RSA(512) Au=RSA Enc=RC4(40) Mac=MD5 Export
6) Cipher Name: SSL2-EXP-RC2-CBC-MD5
Description: SSLv2 Kx=RSA(512) Au=RSA Enc=RC2(40) Mac=MD5 Export
Done
```

To remove a cipher group by using the command line interface

Note: You cannot remove a built-in cipher group. Before removing a user-defined cipher group, make sure that the cipher group is empty.
At the command prompt, type the following commands to remove a user-defined cipher group, and verify the configuration:

- rm ssl cipher <userDefCipherGroupName> [<cipherName> ...]
- show ssl cipher <cipherGroupName>

Example

```
> rm ssl cipher test
Done

> sh ssl cipher test
ERROR: No such resource [cipherGroupName, test]
```

To configure a user-defined cipher group by using the configuration utility

Navigate to **Traffic Management** > **SSL** > **Cipher Groups**, and click **Add**.

To bind a cipher group to an SSL virtual server, service, or service group by using the command line interface

At the command prompt, type one of the following:

- bind ssl vserver <vServerName> -cipherName <string>
- bind ssl service <serviceName> -cipherName <string>
- bind ssl serviceGroup <serviceGroupName> -cipherName <string>

Examples

```
> bind ssl vserver ssl_vserver_test -cipherName test
Done
bind ssl service  nshttps -cipherName test
Done
> bind ssl servicegroup  ssl_svc  -cipherName test
Done
```

To bind a cipher group to an SSL virtual server, service, or service group by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers or navigate to Traffic Management > Load Balancing > Services or navigate to Traffic Management > Load Balancing > Service Groups, and open the virtual server, service, or service group.

2. In Advanced Settings, select SSL Ciphers, and bind a cipher group to the virtual server, service, or service group.

Configuring SSL Actions and Policies

Jul 12, 2017

An SSL policy evaluates incoming traffic and applies a predefined action to requests that match a rule (expression). You have to configure the actions before creating the policies, so that you can specify an action when you create a policy. To put a policy into effect, you must either bind it to a virtual server on the appliance, so that it applies only to traffic flowing through that virtual server, or bind it globally, so that it applies to all traffic flowing through the appliance.

SSL actions define SSL settings that you can apply to the selected requests. You associate an action with one or more policies. Data in client connection requests or responses is compared to a rule specified in the policy, and the action is applied to connections that match the rule (expression).

You can configure classic policies with classic expressions and default syntax policies with default syntax expressions for SSL.
Note: Users who are not experienced in configuring policies at the NetScaler command line usually find using the configuration utility to be considerably easier.
You can associate a user-defined action or a built-in action to a default syntax policy. Classic policies allow only user-defined actions. In default syntax policy, you can also group policies under a policy label, in which case they are applied only when invoked from another policy.

Common uses of SSL actions and policies include per-directory client authentication, support for Outlook web access, and SSL-based header insertions. SSL-based header insertions contain SSL settings required by a server whose SSL processing has been offloaded to the NetScaler appliance.

To configure SSL actions and policies, see the following sections:

- Configuring User-Defined Actions for SSL Policies
- Configuring SSL Policies
- Configuring an SSL Default Syntax Policy
- Configuring Built-in Actions for SSL Default Syntax Policies
- Configuring SSL Policy Labels
- Configuring Per-Directory Client Authentication
- Configuring Support for Outlook Web Access
- Configuring SSL-Based Header Insertion
- Binding SSL Policies to a Virtual Server
- Binding SSL Policies Globally

Configuring User-Defined Actions for SSL Policies

Feb 13, 2017

SSL policies require that you create an action before creating a policy, so that you can specify the actions when you create the policies. In SSL default syntax policies, you can also use the built-in actions. For more information about built-in actions, see Configuring Built-in Actions for SSL Default Syntax Policies.

To configure an SSL action by using the command line interface

At the command prompt, type the following commands to configure an action and verify the configuration:

- add SSL action <name> -clientAuth(DOCLIENTAUTH | NOCLIENTAUTH) -clientCert (ENABLED | DISABLED) certHeader <string> -clientHeader <string> -clientCertSerialNumber (ENABLED | DISABLED) -certSerialHeader <string> **-clientCertSubject** (ENABLED | DISABLED) -certSubjectHeader <string> -clientCertHash (ENABLED | DISABLED) -certHashHeader <string> -clientCertIssuer (ENABLED | DISABLED) -certIssuerHeader <string> -sessionID (ENABLED | DISABLED) -sessionIDheader <string> -cipher (ENABLED | DISABLED) -cipherHeader <string> -clientCertNotBefore (ENABLED | DISABLED) **-certNotBeforeHeader** <string> -clientCertNotAfter (ENABLED | DISABLED) -certNotAfterHeader <string> -OWASupport (ENABLED | DISABLED)
- show ssl action [<name>]

Example

```
> add ssl action Action-SSL-ClientCert -clientCert ENABLED -certHeader "X-Client-Cert"
 Done
> show ssl action Action-SSL-ClientCert
1)     Name: Action-SSL-ClientCert
       Data Insertion Action:
      Cert Header: ENABLED          Cert Tag: X-Client-Cert
 Done
```

To configure an SSL action by using the configuration utility

Navigate to Traffic Management > SSL > Policies and, on the Actions tab, click Add.

Configuring SSL Policies

Feb 13, 2017

Policies on the NetScaler help identify specific connections that you want to process. The processing is based on the actions that are configured for that particular policy. Once you create the policy and configure an action for it, you must either bind it to a virtual server on the NetScaler, so that it applies only to traffic flowing through that virtual server, or bind it globally, so that it applies to all traffic flowing through any virtual server configured on the NetScaler.

The NetScaler SSL feature supports both classic policies and default syntax policies . For a complete description of classic and default syntax expressions, how they work, and how to configure them manually, see Policies and Expressions.

Note: Users who are not experienced in configuring policies at the NetScaler command line will usually find using the configuration utility considerably easier.

Configuring an SSL Default Syntax Policy

Sep 25, 2014

An SSL default syntax policy defines a control or a data action to be performed on requests. SSL policies can therefore be categorized as control policies and data policies:

- **Control policy**. A control policy uses a control action, such as forcing client authentication.
  Note: In release 10.5 or later, deny SSL renegotiation (denySSLReneg) is set, by default, to ALL. However, control policies, such as CLIENTAUTH, trigger a renegotiation handshake. If you use such policies, you must set denySSLReneg to NO.
- **Data policy**. A data policy uses a data action, such as inserting some data into the request.

The essential components of a policy are an expression and an action. The expression identifies the requests on which the action is to be performed. SSL policies use the default expression syntax or the classic expression syntax. For information about expressions and how to configure them, see .

You can configure a default syntax policy with a built-in action or a user-defined action. You can configure a policy with a built-in action without creating a separate action. However, to configure a policy with a user-defined action, first configure the action and then configure the policy.

You can specify an additional action, called an UNDEF action, to be performed in the event that applying the expression to a request has an undefined result.

To configure an SSL default syntax policy by using the command line interface

At the command prompt, type:

add ssl policy <name> -rule <expression> -Action <string> [-undefAction <string>] [-comment <string>]

To configure an SSL default syntax policy by using the configuration utility

Navigate to Traffic Management > SSL > Policies and, on the Polices tab, click Add.

Configuring Built-in Actions for SSL Default Syntax Policies

Feb 13, 2017

Unless you need only the built-in actions in your policies, you have to create the actions before creating the policies, so that you can specify the actions when you create the policies. The built-in actions are of two types, control actions and data actions. You use control actions in control policies, and data actions in data policies.

The built-in control actions are:

- CLIENTAUTH—Perform client certificate authentication.
- NOCLIENTAUTH—Do not perform client certificate authentication.

The built-in data actions are:

- RESET—Close the connection by sending a RST packet to the client.
- DROP—Drop all packets from the client. The connection remains open until the client closes it.
- NOOP—Forward the packet without performing any operation on it.

You can create user-defined data actions. For example, if you enable client authentication, you can create an SSL action to insert client-certificate data into the request header before forwarding the request to the web server. For more information about user-defined actions, see Configuring User-Defined Actions for SSL Policies.

If a policy evaluation results in an undefined state, an UNDEF action is performed. For either a data policy or a control policy, you can specify RESET, DROP, or NOOP as the UNDEF action. For a control policy, you also have the option of specifying CLIENTAUTH or NOCLIENTAUTH.

Examples of built-in actions in a policy

In the following example, if the client sends a cipher other than an EXPORT category cipher, the NetScaler appliance requests client authentication. The client has to provide a valid certificate for a successful transaction.

```
add ssl policy pol1 -rule CLIENT.SSL.CIPHER_EXPORTABLE.NOT -reqAction CLIENTAUTH
```

The following examples assume that client authentication is enabled.

If the version in the certificate provided by the user matches the version in the policy, no action is taken and the packet is forwarded:

```
add ssl policy pol1 -rule CLIENT.SSL.CLIENT_CERT.VERSION.EQ(2) -reqAction NOOP
```

If the version in the certificate provided by the user matches the version in the policy, the connection is dropped:

```
add ssl policy pol1 -rule CLIENT.SSL.CLIENT_CERT.VERSION.EQ(2) -reqAction DROP
```

If the version in the certificate provided by the user matches the version in the policy, the connection is reset:

```
add ssl policy pol1 -rule CLIENT.SSL.CLIENT_CERT.VERSION.EQ(2) -reqAction RESET
```

Configuring SSL Policy Labels

Aug 20, 2013

Policy labels are holders for policies. A policy label helps in managing a group of policies, called a policy bank, which can be invoked from another policy. SSL policy labels can be control labels or data labels, depending on the type of policies that are included in the policy label. You can add only data policies in a data policy label and only control policies in a control policy label. To create the policy bank, you bind policies to the label and specify the order of evaluation of each policy relative to others in the bank of policies for the policy label. At the NetScaler command line, you enter two commands to create a policy label and bind policies to the policy label. In the configuration utility, you select options from a dialog box.

To create an SSL policy label and bind policies to the label by using the command line interface

At the command prompt, type:

- add ssl policylabel <labelName> -type (CONTROL | DATA)
- bind ssl policylabel <labelName> <policyName> <priority> [<gotoPriorityExpression>] [-invoke (<labelType> <labelName>)]

Example

```
add ssl policylabel cpl1 -type CONTROL
add ssl policylabel dpl1 -type DATA
bind ssl policylabel cpl1 -policyName ctrlpol -priority 1
bind ssl policylabel dpl1 -policyName datapol -priority 1
```

To configure an SSL policy label and bind policies to the label by using the configuration utility

Navigate to Traffic Management > SSL > Policy Labels, and configure an SSL policy label.

Configuring Per-Directory Client Authentication

Aug 20, 2013

If you create an action specifying client-side authentication on a per-directory basis, a client identified by a policy associated with the action is not authenticated as part of the initial SSL handshake. Instead, authentication is carried out every time the client wants to access a specific directory on the web server.

For example, if you have multiple divisions in the company, where each division has a folder in which all its files are stored, and you want to know the identity of each client that tries to access files from a particular directory, such as the finance directory, you can enable per-directory client authentication for that directory.

To enable per-directory client authentication, first configure client authentication as an SSL action, and then create a policy that identifies the directory that you want to monitor. When you create the policy, specify your client-authentication action as the action associated with the policy. Then, bind the policy to the SSL virtual server that will receive the SSL traffic.

To create an SSL action and a policy to enable client authentication by using the command line interface

At the command prompt, type the following commands to create an SSL action to enable to client authentication and verify the configuration:

- add ssl action <name> [-clientAuth (DOCLIENTAUTH | NOCLIENTAUTH)]
- show ssl action [<name>]
- add ssl policy <name> -rule <expression> [-action <string>] [-undefAction <string>] [-comment <string>]
- show ssl policy [<name>]

Example

```
> add ssl action ssl-action-1 -clientAuth DOCLIENTAUTH
 Done
> show ssl action ssl-action-1
1)     Name: ssl-action-1
       Client Authentication Action: DOCLIENTAUTH
       Hits: 0
       Undef Hits: 0
       Action Reference Count: 1
 Done
> add ssl policy ssl-pol-1 -rule 'REQ.HTTP.METHOD==GET' -reqaction ssl-action-1
> sh ssl policy ssl-pol-1
       Name: ssl-pol-1
       Rule: REQ.HTTP.METHOD == GET
       Action: ssl-action-1
       UndefAction: Use Global
       Hits: 0
       Undef Hits: 0
 Done
```

To create an SSL action to enable client authentication by using the configuration utility

1. Navigate to Traffic Management > SSL > Policies and, on the Actions tab, click Add.
2. In the Client Authentication list, select Enabled.

To create and bind an SSL policy to enable client authentication by using the configuration utility

1. Navigate to Traffic Management > SSL and, on the Polices tab, click Add.
2. Navigate to Traffic Management > Load Balancing > Virtual Servers and open an SSL virtual server.
   In Advanced Settings, select SSL Policy, and bind the policy to the virtual server.

Configuring Support for Outlook Web Access

Aug 20, 2013

If your SSL configuration is offloading SSL transactions from an Outlook Web Access (OWA) server, you must insert a special header field, FRONT-END-HTTPS: ON, in all HTTP requests directed to the OWA servers. This is required for the OWA servers to generate URL links as https:// instead of http://.

When you enable support for OWA on the NetScaler, the header is automatically inserted into the specified HTTP traffic, and you do not need to configure a specific header insertion. Use SSL policies to identify all traffic directed to the OWA server.

Note: You can enable Outlook Web Access support for HTTP-based SSL virtual servers and services only. You cannot apply it to TCP-based SSL virtual servers and services.
To enable OWA support, first configure OWA support as an SSL action, and then create a policy that identifies the virtual servers or services for which you want to enable OWA support. When you create the policy, specify your OWA support action as the action associated with the policy. Then, bind the policy to the SSL virtual server that will receive the SSL traffic.

To create an SSL action and a policy to enable OWA support by using the command line interface

At the command prompt, type the following commands to create an SSL action to enable OWA support and verify the configuration:

- add ssl action <name> -OWASupport (ENABLED | DISABLED)
- show ssl action [<name>]
- add ssl policy <name> -rule <expression> [-action <string>] [-undefAction <string>] [-comment <string>]
- show ssl policy [<name>]

Example

```
> add ssl action ssl-action-2 -OWASupport ENABLED
 Done
> show ssl action ssl-action-2
1)     Name: ssl-action-2

Undef Hits: 0

Done

To create an SSL action to enable OWA support by using the configuration utility

1. Navigate to Traffic Management > SSL > Policies and, on the Actions tab, click Add.
2. In the Outlook Web Access list, select Enabled.
   Note: Outlook Web Access support is applicable only for SSL virtual server based configurations and transparent SSL service based configurations and not for SSL configurations with back-end encryption.

To create and bind an SSL policy to enable OWA support by using the configuration utility

Navigate to Traffic Management > SSL > Policies, and add a policy.
In the Action list, select the action that you created earlier. Specify an undefined action, and an expression.

Configuring SSL-Based Header Insertion

Dec 22, 2016

Because the NetScaler appliance offloads all SSL-related processing from the servers, the servers receive only HTTP traffic. In some circumstances, the server needs certain SSL information. For example, security audits of recent SSL transactions require the client subject name (contained in an X509 certificate) to be logged on the server.

Such data can be sent to the server by inserting it into the HTTP header as a name-value pair. You can insert the entire client certificate, if required, a hash (also known as fingerprint or thumbprint) of the entire client certificate, or only the specific fields from the certificate, such as the subject, serial number, issuer, signature, SSL session ID, cipher suite, or the not-before or not-after date used to determine certificate validity.

You can enable SSL-based insertion for HTTP-based SSL virtual servers and services only. You cannot apply it to TCP-based SSL virtual servers and services. Also, client authentication must be enabled on the SSL virtual server, because the inserted values are taken from the client certificate that is presented to the virtual server for authentication.

To configure SSL-based header insertion, first create an SSL action for each specific set of information to be inserted, and then create policies that identify the connections for which you want to insert the information. As you create each policy, specify the action that you want associated with the policy. Then, bind the policies to the SSL virtual servers that will receive the SSL traffic.

The following example uses default syntax policies. In the following example, a control policy (ctrlpol) is created to perform client authentication if a request is received for the URL /testsite/file5.html. A data policy (datapol) is created to perform an action (act1) if client authentication is successful, and an SSL action (act1) is added to insert the certificate details and issuer's name in the request before forwarding the request. For other URLs, client authentication is disabled. The policies are then bound to an SSL virtual server (ssl_vserver) that receives the SSL traffic.

Command-line example of configuring SSL-based header insertion

Example

```
> add ssl action act1 -clientCert ENABLED -certHeader mycert -clientcertissuer ENABLED -certIssuerHeader myissuer
> add ssl policy datapol -rule HTTP.REQ.URL.EQ(\"/testsite/file5.html\") -action act1
> add ssl policy ctrlpol -rule HTTP.REQ.URL.EQ(\"/testsite/file5.html\") -action CLIENTAUTH
> bind ssl vserver ssl_vserver -policyName ctrlpol -priority 1
> bind ssl vserver ssl_vserver -policyName datapol -priority 1
 Done
```

To configure SSL-based header insertion by using the configuration utility

1. Navigate to Traffic Management > SSL > Policies.
2. In the details pane, on the Actions tab, click Add.
3. In the Create SSL Action dialog box, set the following parameters:
   - Name*
   - Client Certificate
   - Certificate Tag
   - Client Certificate Issuer
   - Issuer Tag

   * A required parameter
4. Click Create, and then click Close.
5. On the tab, click Add to create a control policy.

6. In the Create SSL Policy dialog box, set the following parameters:
   - Name*
   - Expression
   - Request Action

   * A required parameter
7. Click Create, and then click Close.
8. Create a data policy by repeating steps 5 through 7.
9. In the navigation pane, expand SSL Offload, and then click Virtual Servers.
10. In the details pane, from the list of virtual servers, select the virtual server to which you want to bind the SSL policies, and then click Open.
11. In the Configure Virtual Server (SSL Offload) dialog box, click SSL Settings, and then click SSL Policies.
12. In the Bind/Unbind SSL Policies dialog box, click Insert Policy. Under Policy Name, select the policy that you created in steps 5 through 7.
13. Click OK, and then click Close. A message appears in the status bar, stating that the policy has been bound successfully.
14. Repeat steps 12 and 13 and select the policy that you created in step 8.

Configuring an SSL Policy Action for Inserting Client Certificate Thumbprint in the HTTP Header

NetScaler appliances now support inserting the thumbprint (also called a fingerprint) of a certificate into the header of a request sent to a back-end server. If client authentication is enabled, the appliance computes the thumbprint of the certificate, and uses an SSL policy action to insert the thumbprint into the request. The server searches for the thumbprint, and grants secure access if there is a match.

You must configure an SSL action to enable client certificate fingerprint, specify a header name to insert the client certificate fingerprint, and a digest (hash value) to compute the fingerprint value. The NetScaler appliance supports SHA1 and SHA2 (SHA224, SHA256, SHA384, SHA512) digests. The appliance derives the fingerprint value by computing the specified digest of the DER-encoding of the client certificate. Then, create an SSL policy specifying this action, and bind the policy to an SSL virtual server.

To configure an SSL action for inserting client certificate thumbprint by using the NetScaler CLI

At the command prompt type:

add ssl action <name> -**clientCertFingerprint** (**ENABLED** | **DISABLED**) -**certFingerprintHeader** <string> -**certFingerprintDigest** <certFingerprintDigest>

Arguments

clientCertFingerprint

Insert the certificate's fingerprint into the HTTP header of the request being sent to the web server. The fingerprint is derived by computing the specified hash value (SHA256, for example) of the DER-encoding of the client certificate.

certFingerprintHeader

Name of the header into which to insert the client certificate fingerprint.

certFingerprintDigest

Digest algorithm used to compute the fingerprint of the client certificate.

Possible values: SHA1, SHA224, SHA256, SHA384, SHA512

Example COPY

```
> add ssl action act1 -clientcertfingerprint ENABLED -certfingerprintdigest SHA1 -certfingerprintheader example

Done

> sh ssl action act1

1)      Name: act1

        Type: Data Insertion

        Cert Fingerprint Header: ENABLED

        Cert-Fingerprint Tag: example

        Cert-Fingerprint Digest Algorithm: SHA1

        Hits: 0

        Undef Hits: 0

        Action Reference Count: 0

Done

>

> add ssl policy pol1 -rule true -action act1

Done

> bind ssl vserver v1 -policyName pol1 -priority 10

Done
```

```
> sh ssl vserver v1

        Advanced SSL configuration for VServer v1:

        DH: DISABLED

        DH Private-Key Exponent Size Limit: DISABLED    Ephemeral RSA: ENABLED        Refresh Count: 0

        Session Reuse: ENABLED        Timeout: 120 seconds

        Cipher Redirect: DISABLED

        SSLv2 Redirect: DISABLED

        ClearText Port: 0

        Client Auth: ENABLED    Client Cert Required: Mandatory

        SSL Redirect: DISABLED

        Non FIPS Ciphers: DISABLED

        SNI: DISABLED

        OCSP Stapling: DISABLED

        SSLv2: DISABLED SSLv3: DISABLED TLSv1.0: DISABLED  TLSv1.1: ENABLED  TLSv1.2: DISABLED

        Push Encryption Trigger: Always

        Send Close-Notify: YES

        ECC Curve: P_256, P_384, P_224, P_521
```

```
1)    CertKey Name: intca6    CA Certificate        CRLCheck: Mandatory        CA_Name Sent

2)    CertKey Name: intca5    CA Certificate        CRLCheck: Mandatory        CA_Name Sent

3)    CertKey Name: intca4    CA Certificate        CRLCheck: Mandatory        CA_Name Sent

4)    CertKey Name: intca3    CA Certificate        CRLCheck: Mandatory        CA_Name Sent

5)    CertKey Name: intca2    CA Certificate        CRLCheck: Mandatory        CA_Name Sent

6)    CertKey Name: intca1    CA Certificate        CRLCheck: Mandatory        CA_Name Sent

      Data policy

1)    Policy Name: pol1       Priority: 10

1)    Cipher Name: DEFAULT

      Description: Default cipher list with encryption strength >= 128bit

Done
```

To configure an SSL action for inserting client certificate thumbprint by using the NetScaler GUI

1. Navigate to **Traffic Management** > **SSL** > **Policies**.
2. In the details pane, select the **SSL Actions** tab, and click **Add**.
3. In the **Create SSL Action** dialog box, set the following parameters:
   - Name*
   - Client Certificate Finger Print
   - FingerPrint Tag
   - FingerPrint Digest

     *A required parameter
4. Click **Create**.
5. Select the **SSL Policies** tab, and click **Add**.
6. In the **Create SSL Policy** dialog box, set the following parameters:
   - Name*

- Action
- Expression

*A required parameter

7. Click **Create**.
8. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**.
9. In the details pane, from the list of SSL virtual servers, select the virtual server to which you want to bind the SSL policy, and then click **Edit**.
10. In **Advanced Settings**, click **SSL Policies**.
11. Click below SSL Policy, and in **Policy Binding** dialog box, select the policy created earlier and assign a priority.
12. Click **Bind**.

Binding SSL Policies to a Virtual Server

Aug 20, 2013

The SSL policies that are configured on the NetScaler appliance need to be bound to a virtual server that intercepts traffic directed to the virtual server. If the incoming data matches any of the rules configured in the SSL policy, the policy is triggered and the action associated with it is carried out.

You can also bind SSL policies globally or to custom bind points on the NetScaler appliance. For more information about binding policies on the appliance, see .

To bind an SSL policy to a virtual server by using the command line interface

At the command prompt, type the following command to bind an SSL policy to a virtual server and verify the configuration:

- bind ssl vserver <vServerName> -policyName <string> [-priority <positive_integer>]
- show ssl vserver <vServerName>

Example

```
> bind ssl vserver vs-server -policyName ssl-policy-1 -priority 10
 Done
> show ssl vserver vs-server

      Advanced SSL configuration for VServer vs-server:
      DH: DISABLED
      Ephemeral RSA: ENABLED        Refresh Count: 1000
      Session Reuse: ENABLED        Timeout: 120 seconds
      Cipher Redirect: DISABLED
      SSLv2 Redirect: DISABLED
      ClearText Port: 80
      Client Auth: DISABLED
      SSL Redirect: ENABLED
      SSL-REDIRECT Port Rewrite: ENABLED
      Non FIPS Ciphers: DISABLED
      SSLv2: DISABLED SSLv3: ENABLED  TLSv1: ENABLED

1)    Policy Name: ssl-policy-1       Priority: 10

1)    Cipher Name: DEFAULT
      Description: Predefined Cipher Alias
 Done
```

To bind an SSL policy to a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers, and open an SSL virtual server.
2. In Advanced Settings, select SSL Policy, Click in the SSL Policy section to bind to the virtual server.

Binding SSL Policies Globally

Aug 20, 2013

Globally bound policies are evaluated after all policies bound to services, virtual servers, or other NetScaler bind points are evaluated.

To globally bind an SSL policy by using the command line interface

At the command prompt, type the following command to bind a global SSL policy and verify the configuration:

- bind ssl global - policyName <string> [- priority <positive_integer>]
- show ssl global

Example

```
> bind ssl global -policyName Policy-SSL-2 -priority 90
Done
> sh ssl global
1) Name: Policy-SSL-2 Priority: 90
2) Name: Policy-SSL-1 Priority: 100
Done
```

To bind a global SSL policy by using the configuration utility

1. Navigate to Traffic Management > SSL > Policies.
2. In the details pane, click Global Bindings.
3. In the Bind/Unbind SSL Policies to Global dialog box, click Insert Policy.
4. In the Policy Name drop-down list, select a policy.
5. Optionally, drag the entry to a new position in the policy bank to automatically update the priority level.
6. Click OK. A message appears in the status bar, stating that the policy has been bound successfully.

Use Case 1: Configuring SSL Offloading with End-to-End Encryption

Aug 09, 2017

A simple SSL offloading setup terminates SSL traffic (HTTPS), decrypts the SSL records, and forwards the clear text (HTTP) traffic to the back-end web servers. However, the clear text traffic is vulnerable to being spoofed, read, stolen, or compromised by individuals who succeed in gaining access to the back-end network devices or web servers.

You can, therefore, configure SSL offloading with end-to-end security by re-encrypting the clear text data and using secure SSL sessions to communicate with the back-end Web servers.

Additionally, you can configure the back-end SSL transactions so that the NetScaler appliance uses SSL session multiplexing to reuse existing SSL sessions with the back-end web servers, thus avoiding CPU-intensive key exchange (full handshake) operations. This reduces the overall number of SSL sessions on the server, and therefore accelerates the SSL transaction while maintaining end-to-end security.

To configure SSL Offloading with end-to-end encryption, add SSL based services that represent secure servers with which the NetScaler appliance will carry out end-to-end encryption. Then create an SSL based virtual server, and create and bind a valid certificate-key pair to the virtual server. Bind the SSL services to the virtual server to complete the configuration.

For details on adding SSL based services, see Configuring Services.

For details on adding an SSL virtual server, see Configuring an SSL Based Virtual Server.

For details on creating a certificate-key pair, see Adding a Certificate-Key Pair.

For details on binding a certificate-key pair to a virtual server, see Binding the Certificate Key Pair to the SSL Based Virtual Server.

For details on binding services to a virtual server, see Binding Services to the SSL Based Virtual Server.

To configure an end-to-end encryption deployment, perform the following steps:

- Create SSL services
- Create an SSL virtual server
- Add a certificate-key pair
- Bind the certificate-key pair to the SSL virtual server
- Bind the services to the SSL virtual server

Sample values used in the configuration are listed in the table.

Entity	Name	IP Address	Port
SSL service	service-ssl-1	198.51.100.5	443
SSL service	service-ssl-2	198.51.100.10	443
SSL virtual server	vserver-ssl	203.0.113.5	443
SSL certificate-key pair	certkey-1	-	-

Use Case 2: Configuring Transparent SSL Acceleration

Feb 13, 2017

Note: You need to enable L2 mode on the NetScaler appliance for transparent SSL acceleration to work.
Transparent SSL acceleration is useful for running multiple applications on a secure server with the same public IP, and also for SSL acceleration without using an additional public IP.

In a transparent SSL acceleration setup, the NetScaler appliance is transparent to the client, because the IP address at which the appliance receives requests is the same as the Web server's IP address.

The NetScaler offloads SSL traffic processing from the Web server and sends either clear text or encrypted traffic (depending on the configuration) to the web server. All other traffic is transparent to the NetScaler and is bridged to the Web server. Therefore, other applications running on the server are unaffected.

There are three modes of transparent SSL acceleration available on the NetScaler:

- Service-based transparent access, where the service type can be SSL or SSL_TCP.
- Virtual server-based transparent access with a wildcard IP address (*:443).
- SSL VIP-based transparent access with end-to-end encryption.

Note: An SSL_TCP service is used for non-HTTPS services (for example SMTPS and IMAPS).

Service-based Transparent SSL Acceleration

To enable transparent SSL acceleration using the SSL service mode, configure an SSL or an SSL_TCP service with the IP address of the actual back-end Web server. Instead of a virtual server intercepting SSL traffic and passing it on to the service, the traffic is now directly passed on to the service, which decrypts the SSL traffic and sends clear text data to the back-end server.

The service-based mode allows you to configure individual services with a different certificate, or with a different clear text port. Also, you can also select individual services for SSL acceleration.

You can apply service-based transparent SSL acceleration to data that uses different protocols, by setting the clear text port of the SSL service to the port on which the data transfer between the SSL service and the back-end server occurs.

To configure service-based transparent SSL acceleration, first enable both the SSL and the load balancing features. Then create an SSL based service and configure its clear text port. After the service is created, create and bind a certificate-key pair to this service.

For details on configuring the clear text port for an SSL based service, see "Configuring Advanced SSL Settings."

For details on creating a certificate-key pair and binding a certificate-key pair to a service, see "Adding or Updating a Certificate-Key Pair."

Example

Enable SSL offloading and load balancing.

Create an SSL based service, Service-SSL-1 with the IP address 10.102.20.30 using port 443 and configure its clear text port.

Next, create a certificate-key pair, CertKey-1 and bind it to the SSL service.

Table 1. Entities in the Service-based Transparent SSL Acceleration

Entity	Name	Value
SSL Service	Service-SSL-1	102.20.30
Certificate - Key Pair	Certkey-1	

Virtual Server-based Acceleration with a Wildcard IP Address (*:443)

You can use an SSL virtual server in the wildcard IP address mode if when you want to enable SSL acceleration for multiple servers that host the secure content of a Web site. In this mode, a single-digital certificate is enough for the entire secure Web site, instead of one certificate per virtual server. This results in significant cost savings on SSL certificates and renewals. The wildcard IP address mode also enables centralized certificate management.

To configure global transparent SSL acceleration on the NetScaler appliance, create a *:443 virtual server, which is a virtual server that accepts any IP address associated with port 443. Then, bind a valid certificate to this virtual server, and also bind all services to which the virtual server is to transfer. Such a virtual server can use the SSL protocol for HTTP-based data or the SSL_TCP protocol for non-HTTP-based data.

To configure virtual server-based acceleration with a wildcard IP address

1. Enable SSL, as described in "Enabling SSL Processing."
2. Enable load balancing, as described in "Load Balancing."
3. Add an SSL based virtual server (see "Configuring an SSL-Based Virtual Server" for the basic settings), and set the clearTextPort parameter (described in "Configuring Advanced SSL Settings)."
4. Add a certificate-key pair, as described in "Adding a Certificate-Key Pair."
   Note: The wildcard server will automatically learn the servers configured on the NetScaler, so you do not need to configure services for a wildcard virtual server.

Example

After enabling SSL offloading and load balancing, create an SSL based wildcard virtual server with IP address set to * and port number 443, and configure its clear text port (optional).

If you specify the clear text port, decrypted data will be sent to the backend server on that particular port. Otherwise, encrypted data will be sent to port 443.

Next, create an SSL certificate key pair, CertKey-1 and bind it to the SSL virtual server.

Table 2. Entities in the Virtual Server-based Acceleration with a Wildcard IP Address Example

Entity	Name	IP Address	Port
SSL Based Virtual Server	Vserver-SSL-Wildcard	*	443
Certificate - Key Pair	Certkey-1		

SSL VIP-based Transparent Access with End-To-End Encryption

You can use an SSL virtual server for transparent access with end-to-end encryption if you have no clear text port specified. In such a configuration, the NetScaler terminates and offloads all SSL processing, initiates a secure SSL session, and sends the encrypted data, instead of clear text data, to the web servers on the port that is configured on the wildcard virtual server.

Note: In this case, the SSL acceleration feature runs at the back-end, using the default configuration, with all 34 ciphers available.
To configure SSL VIP based transparent access with end-to-end encryption, Follow instructions for Configuring a Virtual Server-based Acceleration with a Wildcard IP Address (*:443), but do not configure a clear text port on the virtual server.

Use Case 3: Configuring SSL Acceleration with HTTP on the Front End and SSL on the Back End

Feb 13, 2017

In certain deployments, you might be concerned about network vulnerabilities between the NetScaler appliance and the backend servers, or you might need complete end-to-end security and interaction with certain devices that can communicate only in clear text (for example, caching devices).

In such cases, you can set up an HTTP virtual server that receives data from clients that connect to it at the front end and hands the data off to a secure service, which securely transfers the data to the web server.

To implement this type of configuration, you configure an HTTP virtual server on the NetScaler and bind SSL based services to the virtual server. The NetScaler receives HTTP requests from the client on the configured HTTP virtual server, encrypts the data, and sends the encrypted data to the web servers in a secure SSL session.

To configure SSL acceleration with HTTP on the front-end and SSL on the back-end, first enable the load balancing and SSL features on the NetScaler. Then, add SSL based services that represent secure servers to which the NetScaler appliance will send encrypted data. Finally, add an HTTP based virtual server and bind the SSL services to this virtual server.

Example

Enable load balancing and SSL acceleration on the NetScaler.

After enabling load balancing and SSL acceleration, create two SSL based services, Service-SSL-1 and Service-SSL-2, with IP addresses 10.102.20.30 and 10.102.20.31, and both using port 443.

Then create an HTTP based virtual server, Vserver-HTTP-1, with an IP address of 10.102.10.20.

Bind the SSL services to the virtual server to complete the configuration.

Table 1. Entities in the SSL Acceleration with HTTP on the Front End and SSL on the Back End Example

Entity	Name	Value
SSL Service	Service-SSL-1	10.102.20.30
	Service-SSL-2	10.102.20.31
HTTP Based Virtual Server	Vserver-HTTP-1	10.102.10.20

Example COPY

```
en feature lb ssl

add lb vserver vserver-HTTP-1 SSL 10.102.10.20 80

add service Service-SSL-1 10.102.20.30 SSL 443

add service Service-SSL-2 10.102.20.31 SSL 443
```

Use Case 4: SSL Offloading with Other TCP Protocols

Feb 13, 2017

In addition to the secure HTTP (HTTPS) protocol, NetScaler appliances support SSL acceleration for other TCP-based secure protocols. However, only simple requests and response-based TCP application protocols are supported. Applications such as FTPS, that insert the server's IP address and port information in their payloads, are not currently supported.

Note: The STARTTLS feature for SMTP is currently not supported.
The NetScaler supports SSL acceleration for Other TCP protocols with and without end-to-end encryption.

To configure SSL offloading with Other TCP protocols, create a virtual server of type SSL_TCP, bind a certificate-key pair and TCP based services to the virtual server, and configure SSL actions and policies based on the type of traffic expected and the acceleration to be provided.

Follow the instructions in Configuring SSL Offloading, but create an SSL_TCP virtual server instead of an SSL virtual server, and configure TCP services instead of HTTP services.

SSL_TCP Based Offloading with End-to-End Encryption

To configure SSL_TCP-based offloading with end-to-end encryption, both the virtual server that intercepts secure traffic and the services that it forwards the traffic to must be of type SSL_TCP.

Configure SSL_TCP-based offloading as described in Configuring SSL Offloading with End-to-End Encryption, but create an SSL_TCP virtual server instead of an SSL virtual server.

Backend Encryption for TCP Based Data

Some deployments might require the NetScaler appliance to encrypt TCP data received as clear text and send the data securely to the back end servers.

To provide SSL acceleration with back-end encryption for clear text TCP traffic arriving from the client, create a TCP based virtual server and bind it to SSL_TCP based services.

To configure end-to-end encryption for TCP-based data, follow the procedure described in Configuring the SSL feature with HTTP on the Front-End and SSL on the Back-End, but create a TCP virtual server instead of an HTTP virtual server.

Use Case 5: Configuring SSL Bridging

May 26, 2015

An SSL bridge configured on the NetScaler appliance enables the appliance to bridge all secure traffic between the SSL client and the SSL server. The appliance does not offload or accelerate the bridged traffic, nor does it perform encryption or decryption. Only load balancing is done by the appliance. The SSL server must handle all SSL-related processing. Features such as content switching, SureConnect, and cache redirection do not work, because the traffic passing through the appliance is encrypted.

Because the appliance does not carry out any SSL processing in an SSL bridging setup, there is no need for SSL certificates.

Citrix recommends that you use this configuration only if an acceleration unit (for example, a PCI-based SSL accelerator card) is installed in the web server to handle the SSL processing overhead.

Before you configure SSL bridging, first enable SSL and load balancing on the appliance. Then, create SSL_Bridge services and bind them to an SSL_Bridge virtual server. Configure the load balancing feature to maintain server persistency for secure requests.

Example

After enabling SSL and load balancing, create two servers, s1 and s2. Create two SSL_Bridge services, sc1 and src2. Create an SSL_Bridge virtual server and bind the SSL_Bridge services to the virtual server to complete the configuration. At the command line, type:

```
enable ns feature SSL LB
add server s1 10.102.1.101
add server s2 10.102.1.102
add service src1 s1 SSL_BRIDGE 443
add service src2 s2 SSL_BRIDGE 443
add lb vserver ssl_bridge_vip SSL_BRIDGE 10.102.1.200 443
bind lb vserver ssl_bridge_vip src1
bind lb vserver ssl_bridge_vip src2
```

Use Case 6: Configuring SSL Monitoring when Client Authentication is Enabled on the Backend Service

May 26, 2015

Consider a scenario in which you need to load balance servers that require SSL client certificates to validate clients. For this deployment, you need to create an SSL service on the NetScaler appliance, add an HTTPS monitor, add a certificate-key pair, bind this certificate-key pair to the SSL service, and then bind the https monitor to this service. You can use this https monitor to perform health checks on the backend services.

To configure SSL monitoring with client certificate

1. Open an SSH connection to the appliance by using an SSH client, such as PuTTY.
2. Log on the appliance by using the administrator credentials.
3. Add an SSL service. At the command prompt, type:
   add service <name> <serverName> <serviceType> <port>
4. Add an https monitor. At the command prompt, type:
   add lb monitor <name> <type>
5. Add the certificate-key pair that is going to be used as the client cert for that SSL service. At the command prompt, type:
   add ssl certKey <certkeyName> -cert <string> -key <string>
6. Bind this certkey to the SSL service. At the command prompt, type:
   bind ssl service <serviceName> -certkeyName <string>
7. Bind the https monitor to the SSL service. At the command prompt, type:
   bind lb monitor <monitorName> <serviceName>

Now, when the appliance tries to probe the backend service on which client authentication is enabled, the backend service will request a certificate as part of the SSL handshake. When the appliance returns the certificate-key bound in step 6 above, the monitor probe will succeed.

Example

```
add service svc_k 10.102.145.30 SSL 443
add lb monitor sslmon HTTP -respCode 200 -httpRequest "GET /testsite/file5.html" -secure YES
add ssl certKey ctest -cert client_rsa_2048.pem -key client_rsa_2048.ky
bind ssl service svc_k -certkeyName ctest
bind lb monitor sslmon svc_k
> show service svc_k
    svc_k (10.102.145.30:443) - SSL
    State: UP
    Last state change was at Tue Jan 10 13:12:24 2012
    Time since last state change: 0 days, 00:09:37.890
    Server Name: 10.102.145.30
    Server ID : 0 Monitor Threshold : 0
    Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
```

```
    Use Source IP: NO
    Client Keepalive(CKA): NO
    Access Down Service: NO
    TCP Buffering(TCPB): NO
    HTTP Compression(CMP): NO

Use Case 7: Configuring a Secure Content Switching Server

May 26, 2015

An SSL-based content switching virtual server first decrypts the secure data and then redirects the data to appropriately configured servers as determined by the type of content and the configured content switching policies. The packets sent to the server have a mapped IP address as the source IP address.

The following example shows the steps to configure two address-based virtual servers to perform load balancing on the HTTP services. One virtual server, Vserver-LB-HTML, load balances the dynamic content (cgi, asp), and the other, Vserver-LB-Image, load balances the static content (gif, jpeg). The load-balancing method used is the default, LEASTCONNECTION. A content switching SSL virtual server, Vserver-CS-SSL, is then configured to perform SSL acceleration and switching of HTTPS requests on the basis of configured content switching policies.

Example

```
> enable ns feature lb cs ssl
> add lb vserver Vserver-LB-HTML http 10.1.1.2 80
> add lb vserver Vserver-LB-Image http 10.1.1.3 80
> add service s1 10.1.1.4 http 80
> add service s2 10.1.1.5 http 80
> add service s3 10.1.1.6 http 80
> add service s4 10.1.1.7 http 80
> bind lb vserver Vserver-LB-HTML s1
> bind lb vserver Vserver-LB-HTML s2
> bind lb vserver Vserver-LB-Image s3
> bind lb vserver Vserver-LB-Image s4
> add cs vserver Vserver-CS-SSL ssl 10.1.1.1 443
> add cs policy pol1 -url "*.cgi"
> add cs policy pol2 -url "*.asp"
> add cs policy pol3 -url "*.gif"
> add cs policy pol4 -url "*.jpeg"
> bind cs vserver Vserver-CS-SSL -policyName pol1 Vserver-LB-HTML
> bind cs vserver Vserver-CS-SSL -policyName pol2 Vserver-LB-HTML
> bind cs vserver Vserver-CS-SSL -policyName pol3 Vserver-LB-Image
> bind cs vserver Vserver-CS-SSL -policyName pol4 Vserver-LB-Image
> add certkey mykey -cert /nsconfig/ssl/ns-root.cert -key /nsconfig/ssl/ns-root.key
> bind certkey Vserver-CS-SSL mykey
>
> show cs vserver Vserver-CS-SSL
      Vserver-CS-SSL (10.1.1.1:443) - SSL Type: CONTENT
      State: UP
      Last state change was at Tue Jul 13 02:11:37 2010
      Time since last state change: 0 days, 00:02:12.440
      Client Idle Timeout: 180 sec
      Down state flush: ENABLED
```

Disable Primary Vserver On Down : DISABLED
State Update: DISABLED

Vserver IP and Port insertion: OFF
Case Sensitivity: ON
Push: DISABLED Push VServer:
Push Label Rule: none

Ciphers Supported by the NetScaler Appliance

Feb 13, 2017

There is cipher parity between software releases 11.1 and 12.0 except for CHACHA-POLY ciphers. To see the complete list of ciphers supported on your appliance, at the NetScaler CLI, type: **show ciphers**

For the updated list of ciphers supported on a NetScaler appliance, see http://docs.citrix.com/en-us/netscaler/12/ssl/supported-ciphers-list-release-11.html.

FIPS Approved Ciphers

Apr 27, 2017

For the updated list of FIPS-approved ciphers, see http://docs.citrix.com/en-us/netscaler/12/ssl/fips-approved-ciphers.html.

Cipher/Protocol Support Matrix on the NetScaler Appliance

Apr 27, 2017

From release 10.5 build 56.22, NetScaler MPX appliances support full hardware optimization for all ciphers. In earlier releases, part of ECDHE/DHE cipher optimization was done in software.

For the updated cipher/protocol support matrix, see http://docs.citrix.com/en-us/netscaler/12/ssl/cipher_protocl_support_matrix.html.

Server Certificate Support Matrix on the NetScaler Appliance

Apr 27, 2017

For information about the server certificate support matrix, see http://docs.citrix.com/en-us/netscaler/12/ssl/ssl-server-cert-support-matrix.html.

Support for MPX 5900 and MPX/SDX 8900 Platforms

Feb 19, 2018

The MPX 5900 and MPX/SDX 8900 appliances ship with Intel Coleto chips. Use the 'show hardware' command to identify whether your appliance has Coleto (COL) chips.

Code COPY

```
> sh hardware

    Platform: NSMPX-8900 8*CPU+4*F1X+6*E1K+1*E1K+1*COL 8955 30010

    Manufactured on: 10/18/2016

    CPU: 2100MHZ

    Host Id: 0

    Serial no: CRAC5CR8UA

    Encoded serial no: CRAC5CR8UA

 Done

>
```

Limitations:

- DTLS is not supported.
- DH 512 cipher is not supported.
- SSLv2 and SSLv3 protocols are not supported.
- GnuTLS is not supported.
- ECDSA certificates with ECC curves P_224 and P521 are not supported (Not supported on platforms with Cavium chips also.)
- DNSSEC offload is not supported. (DNSSEC is supported in software but offload to hardware is not supported.)

Configuring the MPX 9700/10500/12500/15500 FIPS Appliances

Jan 06, 2017

The Federal Information Processing Standard (FIPS), issued by the US National Institute of Standards and Technologies, specifies the security requirements for a cryptographic module used in a security system. The NetScaler FIPS appliance complies with the second version of this standard, FIPS-140-2.

Note: Henceforth, all references to FIPS imply FIPS-140-2.
The FIPS appliance is equipped with a tamper-proof (tamper-evident) cryptographic module—and a Cavium CN1620-NFBE3-2.0-G on the MPX 9700/10500/12500/15500 FIPS appliances—designed to comply with the FIPS 140-2 Level-2 specifications. The Critical Security Parameters (CSPs), primarily the server's private-key, are securely stored and generated inside the cryptographic module, also referred to as the Hardware Security Module (HSM). The CSPs are never accessed outside the boundaries of the HSM. Only the superuser (nsroot) can perform operations on the keys stored inside the HSM.

The following table summarizes the differences between standard NetScaler and NetScaler FIPS appliances.

Setting	NetScaler appliance	NetScaler FIPS appliance
Key storage	On the hard disk	On the FIPS card
Cipher support	All ciphers	FIPS approved ciphers
Accessing keys	From the hard disk	Not accessible

Configuring a FIPS appliance involves configuring the HSM immediately after completing the generic configuration process. You then create or import a FIPS key. After creating a FIPS key, you should export it for backup. You might also need to export a FIPS key so that you can import it to another appliance. For example, configuring FIPS appliances in a high availability (HA) setup requires transferring the FIPS key from the primary node to the secondary node immediately after completing the standard HA setup.

You can upgrade the firmware version on the FIPS card from version 4.6.0 to 4.6.1, and you can reset an HSM that has been locked to prevent unauthorized logon. Only FIPS approved ciphers are supported on a NetScaler FIPS appliance.

This section includes the following details:

- Configuring the HSM
- Creating and Transferring FIPS Keys
- Configuring FIPS Appliances in a High Availability Setup
- Resetting a Locked HSM
- FIPS Approved Algorithms and Ciphers

Configuring the HSM

Aug 30, 2016

Before you can configure the HSM of your NetScaler FIPS appliance, you must complete the initial hardware configuration. For more information, see Initial Configuration.

Configuring the HSM of your NetScaler FIPS appliance erases all existing data on the HSM. To configure the HSM, you must be logged on to the appliance as the superuser (nsroot account). The HSM is preconfigured with default values for the Security Officer (SO) password and User password, which you use to configure the HSM or reset a locked HSM. The maximum length allowed for the password is 14 alphanumeric characters. Symbols are not allowed.
Important: Do not perform the set ssl fips command without first resetting the FIPS card and restarting the MPX FIPS appliance.
Although the FIPS appliance can be used with the default password values, you should modify them before using it. The HSM can be configured only when you log on to the appliance as the superuser and specify the SO and User passwords.

Important: Due to security constraints, the appliance does not provide a means for retrieving the SO password. Store a copy of the password safely. Should you need to reinitialize the HSM, you will need to specify this password as the old SO password.
Before initializing the HSM, you can upgrade to the latest build of the software. To upgrade to the latest build, see Upgrading or Downgrading the System Software.

After upgrading, verify that the /nsconfig/fips directory has been successfully created on the appliance.

To configure the HSM on an MPX 9700/10500/12500/15500 FIPS appliances by using the command line interface

After logging on to the appliance as the superuser and completing the initial configuration, at the command prompt, type the following commands to configure the HSM and verify the configuration:

1. show ssl fips
2. reset ssl fips
3. reboot
4. set ssl fips -initHSM Level-2 <newSOpassword> <oldSOpassword> <userPassword> [-hsmLabel <string>]
5. save ns config
6. reboot
7. show ssl fips

Example

```
show fips
FIPS Card is not configured
Done
reset fips
reboot
Are you sure you want to restart NetScaler (Y/N)? [N]:y
set ssl fips -initHSM Level-2 sopin12345 so12345 user123 -hsmLabel cavium
This command will erase all data on the FIPS card. You must save the configuration
(saveconfig) after executing this command.

Do you want to continue?(Y/N)y
Done
save ns config
reboot
Are you sure you want to restart NetScaler (Y/N)? [N]:y
show fips
    FIPS HSM Info:
```

```
HSM Label           : NetScaler FIPS
Initialization      : FIPS-140-2 Level-2

Free SRAM Memory    : 50524
Total Crypto Cores  : 3
Enabled Crypto Cores : 3
Done
```

To configure the HSM on an MPX 9700/10500/12500/15500 FIPS appliances by using the configuration utility

1. Navigate to Traffic Management > SSL > FIPS.
2. In the details pane, on the FIPS Infotab, click Reset FIPS.
3. In the navigation pane, click System.
4. In the details pane, click Reboot.
5. In the details pane, on the FIPS Info tab, click Initialize HSM.
6. In the Initialize HSM dialog box, specify values for the following parameters:
   - Security Officer (SO) Password*—new SO password
   - Old SO Password*—old SO password
   - User Password*—user password
   - Level—initHSM (Currently set to Level2 and cannot be changed)
   - HSM Label—hsmLabel

   *A required parameter
7. Click OK.
8. In the details pane, click Save.
9. In the navigation pane, click System.
10. In the details pane, click Reboot.
11. Under FIPS HSM Info, verify that the information displayed for the FIPS HSM that you just configured is correct.

Creating and Transferring FIPS Keys

Nov 04, 2016

After configuring the HSM of your FIPS appliance, you are ready to create a FIPS key. The FIPS key is created in the appliance's HSM. You can then export the FIPS key to the appliance's CompactFlash card as a secured backup. Exporting the key also enables you to transfer it by copying it to the /flash of another appliance and then importing it into the HSM of that appliance. You must enable SIM between two standalone nodes before you export and transfer the keys. In an HA setup, if one of the nodes is replaced with a new appliance, you must enable SIM between this new appliance and the existing appliance of the HA setup before you export or import FIPS keys.

Instead of creating a FIPS key, you can import an existing FIPS key or import an external key as a FIPS key. If you are adding a certificate-key pair of 2048 bits on the MPX 9700/10500/12500/15500 FIPS appliances, make sure that you have the correct certificate and key pair.

Note: If you are planning an HA setup, make sure that the FIPS appliances are configured in an HA setup before creating a FIPS key.

Creating a FIPS Key

Before creating a FIPS key, make sure that the HSM is configured.

To create a FIPS key by using the configuration utility

1. Navigate to Traffic Management > SSL > FIPS.
2. In the details pane, on the FIPS Keys tab, click Add.
3. In the Create FIPS Key dialog box, specify values for the following parameters:
   - FIPS Key Name*—fipsKeyName
   - Modulus*—modulus
   - Exponent*—exponent

   *A required parameter
4. Click Create, and then click Close.
5. On the FIPS Keys tab, verify that the settings displayed for the FIPS key that you just created are correct.

To create a FIPS key by using the command line interface

At the command prompt, type the following commands to create a FIPS key and verify the settings:

- create ssl fipsKey <fipsKeyName> -modulus <positive_integer> [-exponent (3 | F4)]
- show ssl fipsKey [<fipsKeyName>]

Example

```
create fipskey Key-FIPS-1 -modulus 2048 -exponent 3
show ssl fipsKey Key-FIPS-1
FIPS Key Name: Key-FIPS-1 Modulus: 2048   Public Exponent: 3 (Hex: 0x3)
```

Exporting a FIPS Key

Citrix recommends that you create a backup of any key created in the FIPS HSM. If a key in the HSM is deleted, there is no way to create the same key again, and all the certificates associated with it are rendered useless.

In addition to exporting a key as a backup, you might need to export a key for transfer to another appliance.

The following procedure provides instructions on exporting a FIPS key to the /nsconfig/ssl folder on the appliance's

CompactFlash and securing the exported key by using a strong asymmetric key encryption method.

To export a FIPS key by using the command line interface

At the command prompt, type:
export ssl fipsKey <fipsKeyName> -key <string>
Example

export fipskey Key-FIPS-1 -key Key-FIPS-1.key

To export a FIPS key by using the configuration utility

1. Navigate to Traffic Management > SSL > FIPS
2. In the details pane, on the FIPS Keys tab, click Export.
3. In the Export FIPS key to a file dialog box, specify values for the following parameters:
   - FIPS Key Name*—fipsKeyName
   - File Name*—key (To put the file in a location other than the default, you can either specify the complete path or click the Browse button and navigate to a location.)

   *A required parameter
4. Click Export, and then click Close.

Importing an Existing FIPS Key

To use an existing FIPS key with your FIPS appliance, you need to transfer the FIPS key from the hard disk of the appliance into its HSM.

Note: To avoid errors when importing a FIPS key, make sure that the name of the key imported is the same as the original key name when it was created.

To import a FIPS key on the MPX 9700/10500/12500/15500 FIPS appliances by using the command line interface

At the command prompt, type the following commands to import a FIPS key and verify the settings:
- import ssl fipsKey <fipsKeyName> -key <string> -inform SIM -exponent (F4 | 3)
- show ssl fipskey <fipsKeyName>

Example
import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform SIM -exponent F4
show ssl fipskey key-FIPS-2
FIPS Key Name: Key-FIPS-2 Modulus: 2048 Public Exponent: F4 (Hex value 0x10001)

To import a FIPS key by using the configuration utility

1. Navigate to Traffic Management > SSL > FIPS
2. In the details pane, on the FIPS Keys tab, click Import.
3. In the Import as a FIPS Key dialog box, select FIPS key file and set values for the following parameters:
   - FIPS Key Name*
   - Key File Name*—To put the file in a location other than the default, you can either specify the complete path or click Browse and navigate to a location.
   - Exponent*

   *A required parameter

4. Click Import, and then click Close.
5. On the FIPS Keys tab, verify that the settings displayed for the FIPS key that you just imported are correct.

Importing External Keys

In addition to transferring FIPS keys that are created within the NetScaler appliance's HSM, you can transfer external private keys (such as those created on a standard NetScaler, Apache, or IIS) to a FIPS NetScaler appliance. External keys are created outside the HSM, by using a tool such as OpenSSL. Before importing an external key into the HSM, copy it to the appliance's flash drive under /nsconfig/ssl.

Importing an external key as a FIPS key on the MPX 9700/10500/12500/15500 FIPS appliances by using the command line interface

On the MPX 9700/10500/12500/15500 FIPS appliances, the -exponent parameter in the import ssl fipskey command is not required while importing an external key. The correct public exponent is detected automatically when the key is imported, and the value of the -exponent parameter is ignored.

The NetScaler FIPS appliance does not support external keys with a public exponent other than 3 or F4.

You do not need a wrap key on the MPX 9700/10500/12500/15500 FIPS appliances.

You cannot import an external, encrypted FIPS key directly to an MPX 9700/10500/12500/15500 FIPS appliance. To import the key you need to first decrypt the key, and then import it. To decrypt the key, at the shell prompt, type:

openssl rsa -in <EncryptedKey.key> > <DecryptedKey.out>

To import an external key as a FIPS key to an MPX 9700/10500/12500/15500 FIPS appliance by using the command line interface

1. Copy the external key to the appliance's flash drive.
2. If the key is in .pfx format, you must first convert it to PEM format. At the command prompt, type:
   - convert ssl pkcs12 <output file> -import -pkcs12File <input .pfx file name> -password <password>
3. At the command prompt, type the following commands to import the external key as a FIPS key and verify the settings:
   - import ssl fipsKey <fipsKeyName> -key <string> -informPEM
   - show ssl fipskey<fipsKeyName>

Example

```
convert ssl pkcs12 iis.pem -password 123456 -import -pkcs12File iis.pfx
import fipskey Key-FIPS-2 -key iis.pem -inform PEM
show ssl fipskey key-FIPS-2
FIPS Key Name: Key-FIPS-2 Modulus: 0   Public Exponent: F4 (Hex value 0x10001)
```

Note: The modulus is incorrectly displayed as zero in the above example. The discrepancy does not affect SSL functionality.

To import an external key as a FIPS key to an MPX 9700/10500/12500/15500 FIPS appliance by using the configuration utility

1. If the key is in .pfx format, you must first convert it to PEM format.
   1. Navigate to Traffic Management > SSL.
   2. In the details pane, under Tools, click Import PKCS#12.
   3. In the Import PKCS12 File dialog box, set the following parameters:
      - Output File Name*

- PKCS12 File Name*—Specify the .pfx file name.
- Import Password*
- Encoding Format

*A required parameter

2. Navigate to Traffic Management > SSL > FIPS
3. In the details pane, on the FIPS Keys tab, click Import.
4. In the Import as a FIPS Key dialog box, select PEM file, and set values for the following parameters:
   - FIPS Key Name*
   - Key File Name*—To put the file in a location other than the default, you can either specify the complete path or click Browse and navigate to a location.

   *A required parameter
5. Click Import, and then click Close.
6. On the FIPS Keys tab, verify that the settings displayed for the FIPS key that you just imported are correct.

Configuring FIPS Appliances in a High Availability Setup

Feb 13, 2017

You can configure two appliances in a high availability (HA) pair as FIPS appliances. For information about configuring an HA setup, see High Availability.

Note: Citrix recommends that you use the configuration utility (GUI) for this procedure. If you use the command line (CLI), make sure that you carefully follow the steps as listed in the procedure. Changing the order of steps or specifying an incorrect input file might cause inconsistency that requires that the appliance be restarted. In addition, if you use the CLI, the create ssl fipskey command is not propagated to the secondary node. When you execute the command with the same input values for modulus size and exponent on two different FIPS appliances, the keys generated are not identical. You have to create the FIPS key on one of the nodes and then transfer it to the other node. But if you use the configuration utility to configure FIPS appliances in an HA setup, the FIPS key that you create is automatically transferred to the secondary node. The process of managing and transferring the FIPS keys is known as secure information management (SIM).
Important: On the MPX 9700/10500/12500/15500 FIPS appliances, the HA setup should be completed within six minutes. If the process takes longer than six minutes, the internal timer of the FIPS card expires and the following error message appears:
ERROR: Operation timed out or repeated, please wait for 10 mins and redo the SIM/HA configuration steps.

If this message appears, restart the appliance or wait for 10 minutes, and then repeat the HA setup procedure.

In the following procedure, appliance A is the primary node and appliance B is the secondary node.

To configure FIPS appliances in a high availability setup by using the command line interface

1. **On appliance A**, open an SSH connection to the appliance by using an SSH client, such as PuTTY.
2. Log on to the appliance, using the administrator credentials.
3. Initialize appliance A as the source appliance. At the command prompt, type:
   init ssl fipsSIMsource <certFile>
4. Copy this <certFile> file to appliance B, in the /nconfig/ssl folder.
5. **On appliance B**, open an SSH connection to the appliance by using an SSH client, such as PuTTY.
6. Log on to the appliance, using the administrator credentials.
7. Initialize appliance B as the target appliance. At the command prompt, type:
   init ssl fipsSIMtarget <certFile> <keyVector> <targetSecret>
8. Copy this <targetSecret> file to appliance A.
9. **On appliance A**, enable appliance A as the source appliance. At the command prompt, type:
   enable ssl fipsSIMSource <targetSecret> <sourceSecret>
10. Copy this <sourceSecret> file to appliance B.
11. **On appliance B**, enable appliance B as the target appliance. At the command prompt, type:
    enable ssl fipsSIMtarget <keyVector> <sourceSecret>
12. **On appliance A**, create a FIPS key, as described in Creating a FIPS Key.
13. Export the FIPS key to the appliance's hard disk, as described in Exporting a FIPS Key.

14. Copy the FIPS key to the hard disk of the secondary appliance by using a secure file transfer utility, such as SCP.
15. **On appliance B**, import the FIPS key from the hard disk into the HSM of the appliance, as described in Importing an Existing FIPS Key.

To configure FIPS appliances in a high availability setup by using the configuration utility

1. On the appliance to be configured as the source appliance, navigate to Traffic Management > SSL > FIPS.
2. In the details pane, on the FIPS Info tab, click Enable SIM.
3. In the Enable HA Pair for SIM dialog box, in the Certificate File Name text box, type the file name, with the path to the location at which the FIPS certificate should be stored on the source appliance.
4. In the Key Vector File Name text box, type the file name, with the path to the location at which the FIPS key vector should be stored on the source appliance.
5. In the Target Secret File Name text box, type the location for storing the secret data on the target appliance.
6. In the Source Secret File Name text box, type the location for storing the secret data on the source appliance.
7. Click OK. The FIPS appliances are now configured in HA mode.
8. Create a FIPS key, as described in Creating a FIPS Key. The FIPS key is automatically transferred from the primary to the secondary.

Example

In the following example, source.cert is the certificate on the source appliance, stored in the default directory, /nsconfig/ssl. This certificate must be transferred to the same location (/nsconfig/ssl) on the target appliance. The file target.secret is created on the target appliance and copied to the source appliance. The file source.secret is created on the source appliance and copied to the target appliance.

On the source appliance

```
init fipsSIMsource /nsconfig/ssl/source.cert
```

On the target appliance

```
init fipsSIMtarget /nsconfig/ssl/source.cert /nsconfig/ssl/target.key /nsconfig/ssl/target.secret
```

On the source appliance

```
enable fipsSIMsource /nsconfig/ssl/target.secret /nsconfig/ssl/source.secret
```

On the target appliance

```
enable fipsSIMtarget /nsconfig/ssl/target.key /nsconfig/ssl/source.secret
```

On the source appliance

```
create ssl fipskey fips1 -modulus 2048 -exponent f4
export fipskey fips1 -key /nsconfig/ssl/fips1.key
```

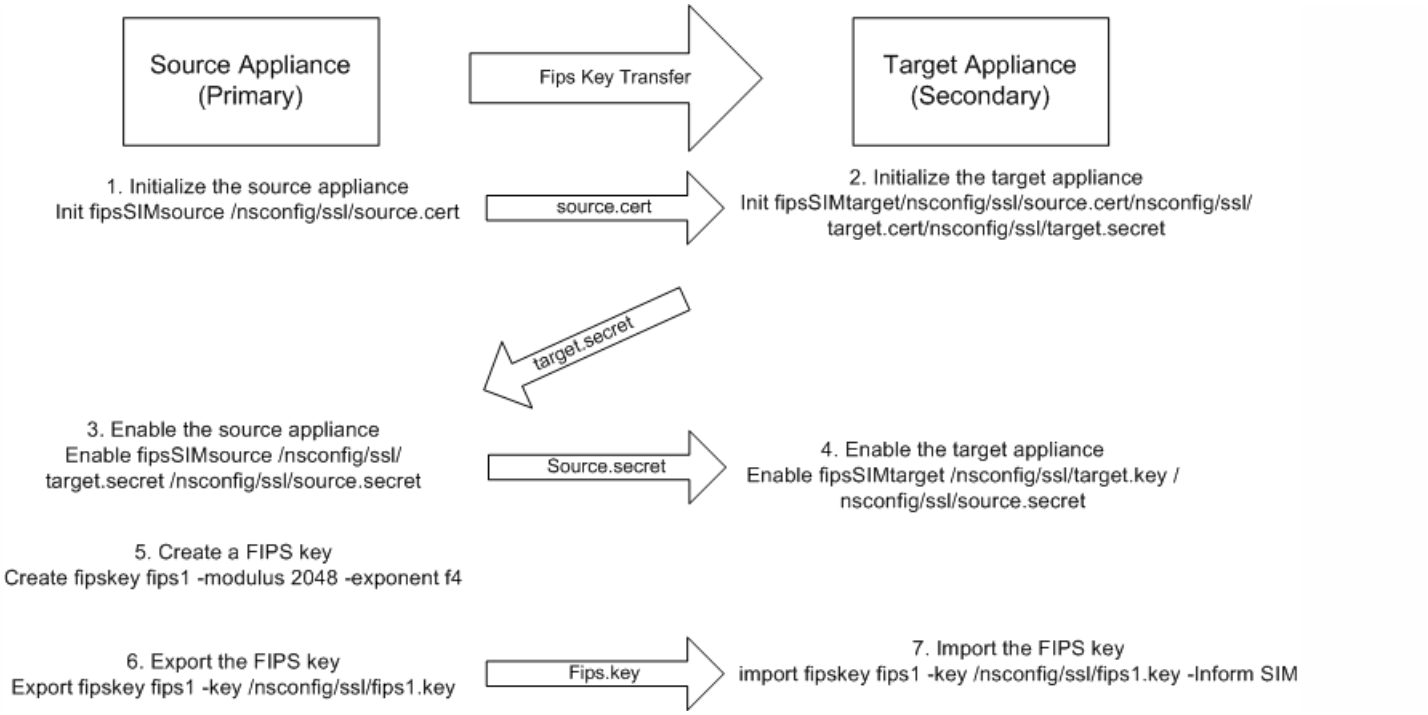
Copy this key into the hard disk of the target appliance.

On the target appliance

```
import fipskey fips1 -key /nsconfig/ssl/fips1.key
```

The following diagram summarizes the transfer process.

Figure 1. Transferring the FIPS Key-Summary



Updating the Firmware to Version 2.2 on a FIPS Card

Apr 25, 2017

FIPS firmware version 2.2 supports TLS protocol versions 1.1 and 1.2. From the command line, you can update the firmware version of the FIPS card of a NetScaler MPX 9700/10500/12500/15500 FIPS appliance from version 1.1 to version 2.2.

For successful SIM key propagation from primary to secondary in a high availability (HA) pair, the Cavium firmware version on each appliance should be identical. Perform the firmware update on the secondary appliance first. If executed on the primary appliance first, the long-running update process causes a failover.

Limitations

- Secure renegotiation is supported only on SSL virtual servers and front-end SSL services.
- Creating a certificate signing request by using a key that was created on firmware version 1.1 and updated to firmware version 2.2 fails.
- You cannot create a 1024-bit RSA key on firmware version 2.2. However, if you have imported or created a 1024-bit FIPS key on firmware version 1.1 and you then update to firmware version 2.2, you can use that FIPS key on firmware version 2.2.
- 1024-bit RSA keys are not supported.
- Secure renegotiation using SSLv3 protocol is not supported.
- After you upgrade the firmware, TLSv1.1 and TLSv1.2 are disabled by default on the existing virtual server, internal, front end, and backend services. To use TLS 1.1/1.2, you must explicitly enable these protocols, on the SSL entities, after the upgrade.
- FIPS keys that are created in firmware version 2.2 are not available if you downgrade the firmware to version 1.1.

Prerequisites

Download the following files from the download page on www.citrix.com. The files must be stored in the /var/nsinstall directory on the appliance.

- FW 2.2 File: FW-2.2-130013
- FW 2.2 Signature File: FW-2.2-130013.sign

FW-2.2-130013 is the recommended firmware version. It includes fixes to improve DRBG.

To update the FIPS firmware to version 2.2 on a standalone appliance

1. Log on to the appliance by using the administrator credentials.
2. At the prompt, type the following command to confirm that the FIPS card is initialized.
   show fips

   ```
   FIPS HSM Info:
    HSM Label  : NetScaler FIPS
    Initialization  : FIPS-140-2 Level-2
    HSM Serial Number : 3.0G1235-ICM000264
    HSM State  : 2
    HSM Model  : NITROX XL CN1620-NFBE

    Hardware Version : 2.0-G
    Firmware Version : 1.1
    Firmware Release Date : Jun04,2010

    Max FIPS Key Memory : 3996
    Free FIPS Key Memory : 3992
    Total SRAM Memory : 467348
    Free SRAM Memory : 62512
    Total Crypto Cores : 3
    Enabled Crypto Cores : 1
    Done
   ```
3. Save the configuration. At the prompt, type:
   save config
4. Perform the update. At the prompt, type:
   update ssl fips -fipsFW <path to the extracted contents>/CN16XX-NFBE-FW-2.2-1300013

   and press Y when the following prompt appears:
   This command will update compatible version of the FIPS firmware. You must save the current configuration (saveconfig) before executing this command. You must reboot the system after execution o
   Done
   Note: You only need to specify the firmware file, because the firmware signature file is placed in the same location.
   The update takes up to ten seconds. The update command is blocking, which means that no other actions are executed until the command finishes. The command prompt reappears when execution of the command is completed.
5. Restart the appliance. At the prompt, type:
   reboot

   ```
   Are you sure you want to restart NetScaler (Y/N)? [N]:Y
   ```
6. Verify that the update is successful. At the prompt, type:
   show fips

   The firmware version displayed in the output should be 2.2. For example:

   ```
   > sh fips
    FIPS HSM Info:
     HSM Label  : NetScaler FIPS
     Initialization  : FIPS-140-2 Level-2
   ```

```
HSM Serial Number : 2.1G1207-IC002429
HSM State  : 2
HSM Model  : NITROX XL CN1620-NFBE

Hardware Version : 2.0-G
Firmware Version : 2.2
Firmware Build      : NFBE-FW-2.2-130013
Max FIPS Key Memory : 3996
Free FIPS Key Memory : 3982
Total SRAM Memory : 467348
Free SRAM Memory : 50472
Total Crypto Cores : 3
Enabled Crypto Cores : 1
Done
```

To update the FIPS firmware to version 2.2 on appliances in a high availability pair

1. Log on to the secondary node and perform the update as described in To update the FIPS firmware to version 2.2 on a standalone NetScaler.
   Force the secondary node to become primary. At the prompt, type:

   force failover

   and press **Y** at the confirmation prompt.
2. Log on to the new secondary node (old primary) and perform the update as described in To update the FIPS firmware to version 2.2 on a standalone NetScaler.
3. Force the new secondary node to become primary again. At the prompt, type:
   force failover

   and press **Y** at the confirmation prompt.

To update the FIPS firmware to version 1.1 on a standalone appliance

1. Download the nfb_firmware-r1235_100604 and nfb_firmware-r1235_100604.sign files, to the same directory on the appliance, from the download page on www.citrix.com.
2. Log on to the appliance by using the administrator credentials.
3. At the prompt, type:

   update ssl fips -fipsFW /<full path to the file>/nfb_firmware-r1235_100604

Resetting a Locked HSM

Feb 13, 2017

The HSM becomes locked (no longer operational) if you change the SO password, restart the appliance without saving the configuration, and make three unsuccessful attempts to change the password. This is a security measure for preventing unauthorized access attempts and changes to the HSM settings.

Important: To avoid this situation, save the configuration after initializing the HSM.
If the HSM is locked, you must reset the HSM and restart the appliance to restore the default passwords. You can then use the default passwords to access the HSM and configure it with new passwords. When finished, you must save the configuration and restart the appliance.

Caution: Do not reset the HSM unless it has become locked.

To reset a locked HSM by using the command line interface

At the command prompt, type the following commands to reset and re-initialize a locked HSM:

- reset ssl fips
- reboot -warm
- set ssl fips -initHSM Level-2 <new SO password> <old SO password> <user password> [-hsmLabel <string>]
- save ns config
- reboot -warm

Example

```
reset fips
reboot -warm
set fips -initHSM Level-2 newsopin123 sopin123 userpin123 -hsmLabel NSFIPS
saveconfig
reboot -warm
```

Note: By default the HSM passwords are preconfigured. The <Old_SO_Password> = so12345, <User_Password> = user123, <New_SO_Password> = sopin12345, <New_User_Password> = userpin123.

To reset a locked HSM by using the configuration utility

1. Navigate to Traffic Management > SSL > FIPS
2. In the details pane, on the FIPS Info tab, click Reset FIPS.
3. Configure the HSM, as described in Configuring the HSM.
4. In the details pane, click Save.

FIPS Approved Algorithms and Ciphers

Feb 13, 2017

For the updated list of ciphers supported on all FIPS appliances, see FIPS Approved CIphers.

For information about the Cipher/Protocol support matrix, see Cipher/Protocol Support Matrix.

Configuring the MPX 14000 FIPS Appliance

Jan 04, 2018

> **Note**
>
> This platform is supported in release 11.1 build 51.x and later.

> **Important**
>
> Configuration steps for NetScaler MPX 14000 FIPS and NetScaler MPX 9700/10500/12500/15500 FIPS appliances are different.

A FIPS appliance is equipped with a tamper-proof (tamper-evident) cryptographic module—a Cavium CNN3560-NFBE-G—designed to comply with the FIPS 140-2 Level-3 specifications (from release 11.1 build 56.x). The Critical Security Parameters (CSPs), primarily the server's private-key, are securely stored and generated inside the cryptographic module, also referred to as the Hardware Security Module (HSM). The CSPs are never accessed outside the boundaries of the HSM. Only the superuser (nsroot) can perform operations on the keys stored inside the HSM.

Before configuring a FIPS appliance, you must check the state of the FIPS card and then initialize the card. Create a FIPS key and server certificate, and add any additional SSL configuration.

For information about the FIPS ciphers supported, see FIPS Approved Algorithms and Ciphers. The cipher/protocol matrix is available here.

For information about configuring FIPS appliances in a high availability setup, see Configuring FIPS Appliances in a High Availability Setup.

Limitations

1. SSL renegotiation using the SSLv3 protocol is not supported on the back end of an MPX FIPS appliance.
2. 1024-bit and 4096-bit keys and exponent value of 3 are not supported.

Configuring the HSM on the MPX 14000 FIPS Appliance

Jan 04, 2018

Before configuring the HSM on an MPX 14000 FIPS appliance, you must check the state of your FIPS card to verify that the driver loaded correctly, and then initialize the card.

At the command prompt, type:

> show fips

FIPS Card is not configured

Done

The message “ERROR: Operation not permitted - no FIPS card present in the system” appears if the driver is not loaded correctly.

The appliance must be restarted three times for proper initialization of the FIPS card.

Important

- Verify that the /nsconfig/fips directory has been successfully created on the appliance.
- Do not save the configuration before you restart the appliance for the 3rd time.

Perform the following steps to initialize the FIPS card:

1. Reset the FIPS card.
2. Restart the appliance.
3. Set the security officer password for partitions 0 and 1, and the user password for partition 1.
   Note: The set or reset command takes more than 60 seconds to run.
4. Save the configuration.
5. Verify that the password encrypted key for the master partition (master_pek.key) has been created in the /nsconfig/fips/ directory.
6. Restart the appliance.
7. Verify that the password encrypted key for the default partition (master_pek.key) has been created in the /nsconfig/fips/ directory.
8. Restart the appliance.
9. Verify that the FIPS card is UP.

Note

From release 11.1 build 56.x, the following message appears when you run the **set fips** command:

> This command will erase all data on the FIPS card. You must save the configuration (saveconfig) after executing this command. [Note: On MPX/SDX 14xxx FIPS platform, the FIPS security is at Level-3 by default, and the -initHSM Level-2 option is internally converted to Level-3] Do you want to continue?(Y/N)y

To initialize the FIPS card by using the NetScaler command line

At the command prompt, type the following commands:

> **reset fips**

Done

> **reboot**

> **set fips -initHSM Level-2** so12345 so12345 user123 **-hsmLabel** NSFIPS

This command will erase all data on the FIPS card. You must save the configuration (saveconfig) after executing this command. [Note: On MPX/SDX 14xxx FIPS platform, the FIPS security is at Level-3 by default, and the -initHSM Level-2 option is internally converted to Level-3] Do you want to continue?(Y/N)y

Done

> **saveconfig**

Done

> **reboot**

> **reboot**

> **show fips**

FIPS HSM Info:

HSM Label : NSFIPS

Initialization : FIPS-140-2 Level-3

HSM Serial Number : 3.0G1501-ICM000083

HSM State : 2

HSM Model : NITROX-III CNN35XX-NFBE

Hardware Version : 0.0-G

Firmware Version : 1.0

Firmware Build : NFBE-FW-1.0-48

Max FIPS Key Memory : 102235

Free FIPS Key Memory : 102233

```
        Total SRAM Memory     : 557396
        Free SRAM Memory      : 255456
        Total Crypto Cores    : 63
        Enabled Crypto Cores  : 63
Done
```

Creating FIPS Keys on the MPX 14000 FIPS Appliance

Jan 18, 2017

You can create a FIPS key on your MPX 14000 FIPS appliance or import an existing FIPS key to the appliance. The MPX 14000 FIPS appliance supports only 2048-bit and 3072-bit keys and an exponent value of F4. For PEM keys, an exponent is not required. Verify that the FIPS key is created correctly. Create a certificate signing request and a server certificate. Finally, add the certificate-key pair to your appliance.

> **Note**
>
> 1024-bit and 4096-bit keys and an exponent value of 3 are not supported.

To create a FIPS key by using the NetScaler command line

At the command prompt, type:

create ssl fipsKey <fipsKeyName> **-modulus** <positive_integer> **-exponent F4**

```
> create fipsKey  f1 -modulus 2048 -exponent F4

Done
```

To import a FIPS key by using the NetScaler command line

At the command prompt, type:

import ssl fipsKey <fipsKeyName> **-key** <string> [**-inform** <inform>] [**-wrapKeyName** <string>] [**-iv**<string>] **-exponent F4**]

```
>import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform SIM -exponent F4

Done

>import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform PEM

Done
```

Verify that the FIPS key is created or imported correctly by running the **show fipskey** command.

```
> show fipskey

1)      FIPS Key Name: Key-FIPS-2

Done
```

To create a certificate signing request by using the NetScaler command line

At the command prompt, type:

create ssl certReq <reqFile> (**-keyFile** <input_filename> | **-fipsKeyName** <string>) [**-keyform** (DER | **PEM**) {-**PEMPassPhrase** }] -**countryName** <string> -**stateName** <string> -**organizationName**<string> [-**organizationUnitName** <string>] [-**localityName** <string>] [-**commonName** <string>] [-**emailAddress** <string>] {-**challengePassword** } [-**companyName** <string>] [-**digestMethod** (SHA1 | SHA256)]

```
>create certreq f1.req –fipsKeyName  f1 -countryName US  -stateName CA -organizationName Citrix -companyName Citrix -commonNar

Done
```

To create a server certificate by using the NetScaler command line

At the command prompt, type:

create ssl cert <certFile> <reqFile> <certType> [**-keyFile**

<input_filename>] [**-keyform** (**DER** | **PEM**) {**-PEMPassPhrase** }] [**-days**

<positive_integer>] [**-certForm** (**DER** | **PEM**)] [**-CAcert**

<input_filename>] [**-CAcertForm** (**DER** | **PEM**)] [**-CAkey** <input_filename>]

[**-CAkeyForm** (**DER** | **PEM**)] [**-CAserial** <output_filename>]

```
> create cert f1.cert f1.req SRVR_CERT -CAcert ns-root.cert -CAkey ns-root.key -CAserial ns-root.srl -days 1000

Done
```

The above example creates a server certificate using a local root CA on the appliance.

To add a certificate-key pair by using the NetScaler command line

At the command prompt, type:

add ssl certKey <certkeyName> (**-cert** <string> [**-password**]) [**-key**

<string> | **-fipsKey** <string> | **-hsmKey** <string>] [**-inform** <inform>]

[**-expiryMonitor** (**ENABLED** | **DISABLED**) [**-notificationPeriod**

<positive_integer>]] [**-bundle** (**YES** | **NO**)]

```
> add certkey cert1 -cert f1.cert -fipsKey f1

Done
```

After creating the FIPS key and server certificate, you can add the generic SSL configuration. Enable the features that are required for your deployment. Add servers, services, and SSL virtual servers. Bind the certificate-key pair and the service to the SSL virtual server. Save the configuration.

```
>enable ns feature SSL LB

Done

>add server s1 10.217.2.5

Done

>add service sr1 s1 HTTP 80

Done

>add lb vserver v1 SSL 10.217.2.172 443

Done

>bind ssl vserver v1 –certkeyName cert1

Done

>bind lb vserver v1 sr1

Done

> saveconfig

Done
```

The basic configuration of your MPX 14000 FIPS appliance is now complete.

For information about configuring secure HTTPS, click here.

For information about configuring secure RPC, click here.

Configuring an SDX 14000 FIPS Appliance

Jan 04, 2018

> **Note**
>
> This platform is supported in release 11.1 build 52.x and later.

A Citrix NetScaler SDX appliance is a multitenant platform on which you can provision and manage multiple virtual NetScaler instances. The SDX appliance addresses cloud computing and multitenancy requirements by allowing a single administrator to configure and manage the appliance and delegate the administration of each hosted instance to tenants.

A NetScaler SDX 14030/14060/14080 FIPS appliance provides the capabilities of an SDX appliance with FIPS functionality. It is equipped with a tamper-proof (tamper-evident) cryptographic module—a Cavium CNN3560-NFBE-G—designed to comply with the FIPS 140-2 Level-3 specifications (from release 11.1 build 56.x). The Critical Security Parameters (CSPs), primarily the server's private-key, are securely stored and generated inside the cryptographic module, also referred to as the Hardware Security Module (HSM). The CSPs are never accessed outside the boundaries of the HSM. Only the superuser (nsroot) can perform operations on the keys stored inside the HSM.

A NetScaler SDX 14030/14060/14080 FIPS appliance contains one FIPS HSM module with 63 cores. The FIPS HSM module can be partitioned up to a maximum of 32 partitions. The SDX administrator can assign dedicated key storage, cryptographic resources, and number of crypto SSL FIPS cores to each partition. Keys and resources allocated to a partition are dedicated and secure and cannot be accessed or shared by another partition.

The FIPS HSM partition that you create can be assigned or attached to a VPX instance at the time of provisioning the instance, or later by editing the instance. The FIPS partition created and attached to an instance acts like a virtual HSM module for that particular instance.

The VPX instances on an SDX 14030/14060/14080 FIPS appliance are assigned a FIPS virtual function (VF) partition, which is treated as an isolated FIPS virtual card or HSM. Therefore, the steps to configure a FIPS partition inside a VPX instance are similar to the steps to configure an MPX FIPS appliance. For compliance details, see the security policy details on the U.S. National Institute of Standards and Technology (NIST) website.

> **Important**
>
> Each key includes a private and a public key. As a result, it occupies two key spaces. Therefore, the maximum number of keys is limited to one less than half the key store size.

Limitations

Feb 16, 2017

1. SSL renegotiation using the SSLv3 protocol is not supported on the back end of an SDX FIPS appliance.
2. 1024-bit and 4096-bit keys and an exponent value of 3 are not supported.
3. Backup and restore is not supported.
4. Cluster and administrative domains are not supported.

Terminology

Feb 16, 2017

Zeroize: Reset the HSM. All the data on the HSM is deleted. This is a mandatory step before the HSM is initialized.

Initialize: Set the HSM capabilities. The NetScaler SDX FIPS appliance complies with FIPS-140-2 level 2. You can create partitions after you initialize the chip.

Key store size: Number of keys that can be stored on a partition. A maximum of 102235 keys can be specified. The maximum number of keys that can be stored is one less than half the number specified. For example, if you specify 100, you can create only 49 keys because one of the keys is the RSA key pair that consumes 2 key stores.

Crypto Core Capacity: Number of crypto cores assigned to a partition. A maximum of 63 cores are available.

SSL Context: Number of concurrent SSL connections that can be created on a partition.

Initializing the HSM

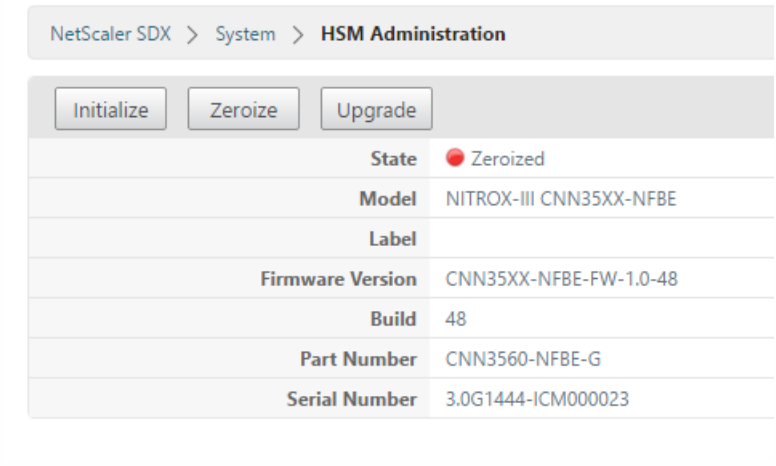
Oct 05, 2016

Before initializing the HSM, you must first zeroize it.

To zeroize the HSM by using the Management Service

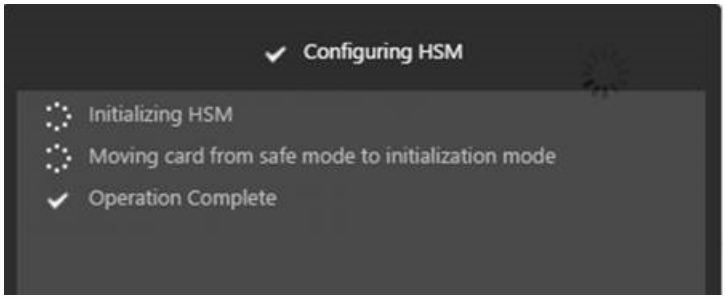
1. Open a browser and log on to the appliance.
2. On the **Configuration** tab, navigate to **System** > **HSM Administration**, and in the details plane, click **Zeroize**.

All data is wiped from the FIPS chip, and the state appears as "Zeroized." Any HSM partitions created earlier are deleted.

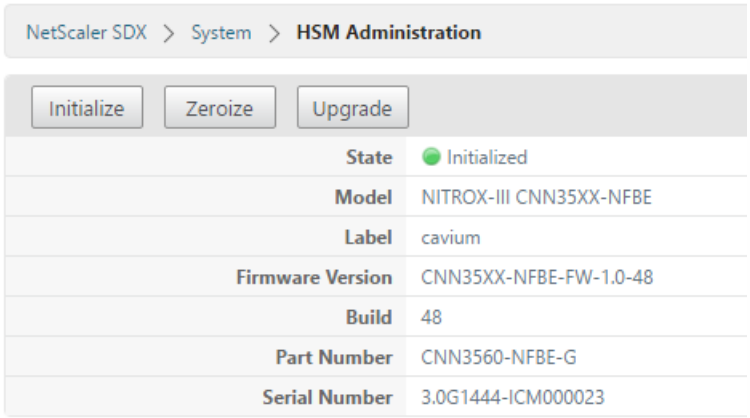


To initialize the HSM by using the Management Service

1. On the **Configuration** tab, navigate to **System** > **HSM Administration**, and in the details plane, click **Initialize**.
2. Type a new user name, specify a password, and click **OK**.



The card state appears as "Initialized."



Creating Partitions

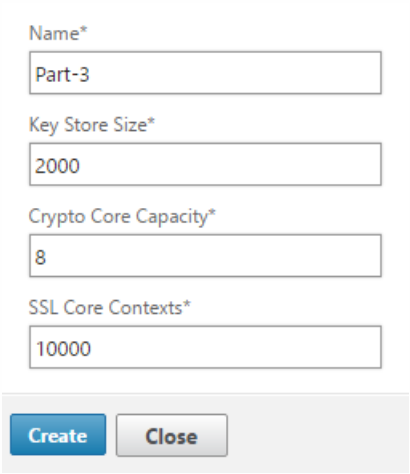
Oct 05, 2016

Create partitions for different tenants and specify the cryptographic resources for each partition. Each instance is assigned one partition, and a partition can be assigned to only one instance. Deleting an instance deletes the partition assigned to the instance. As a result, the partition data is also deleted and not left unsecured or accessible later. Number of keys and SSL context assignment depends on your application. For information about number of cores to assign, see the NetScaler datasheet.

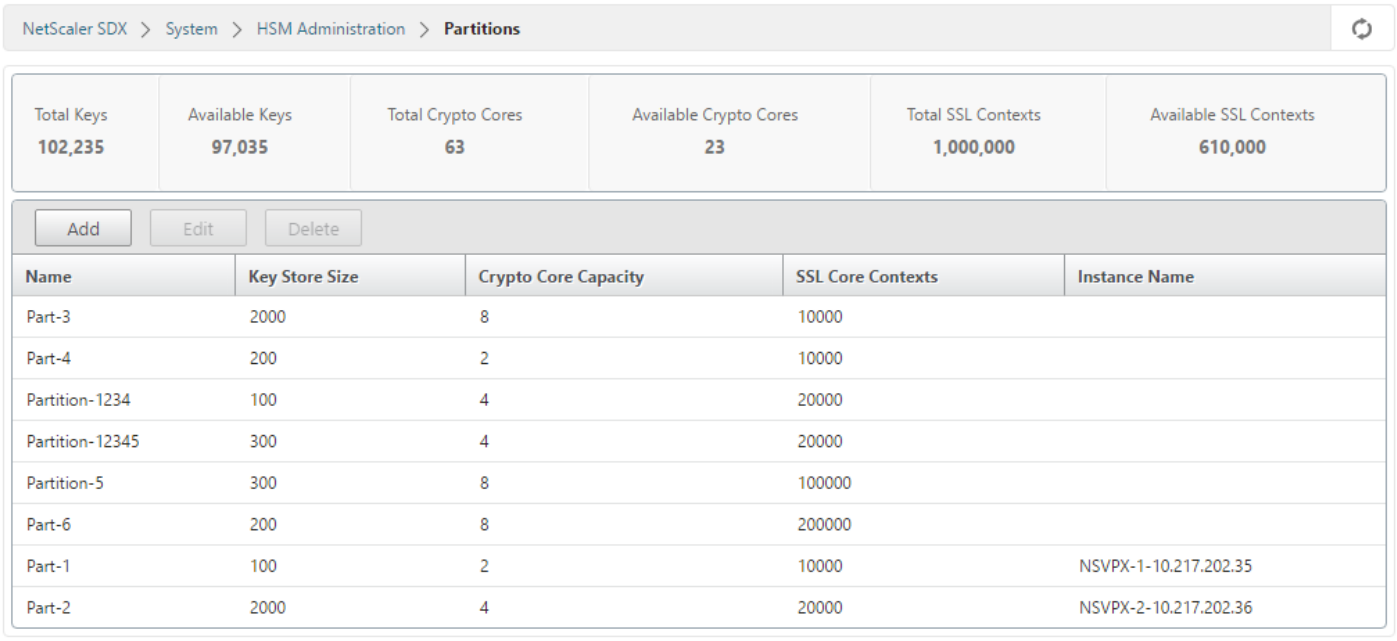
> ## Important
>
> After you assign a key store size and cores to an HSM partition, you cannot change them at run time. You must first detach the partition from the instance.

To create a partition by using the Management Service

1. On the Configuration tab, navigate to **System** > **HSM Administration** > **Partitions**, and in the details plane, click **Add**.
2. Specify a name for the partition, and the resources to be assigned to this partition.
3. Click **OK**.



The summary page displays all the partitions that were created. Some partitions are assigned an instance while some are free partitions.



Provisioning a New Instance or Modifying an Existing Instance and Assigning a Partition

Oct 05, 2016

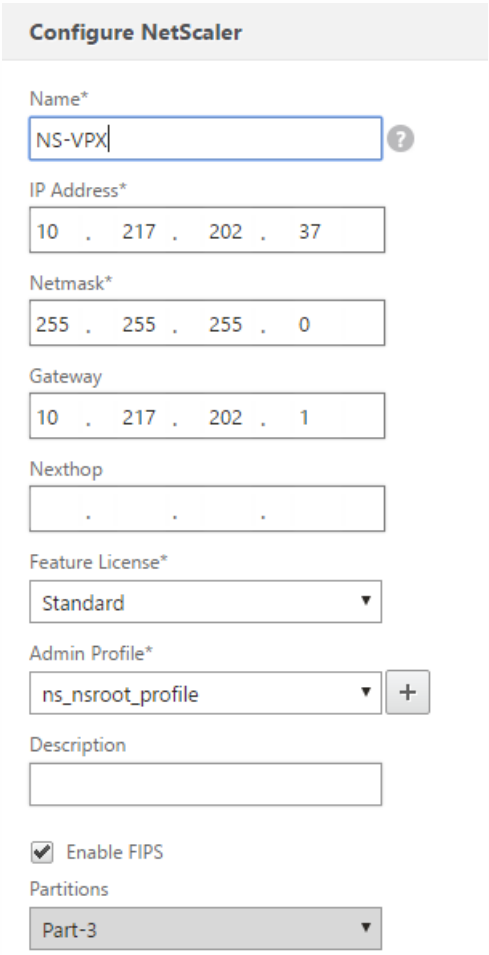
After creating the partitions, you must assign them to instances.

Important

- You can attach only one FIPS partition to an instance.
- An instance with a FIPS partition can be assigned only one CPU core.
- You can assign either a FIPS partition or an SSL core to an instance, but not both.

To provision a new instance or modify an existing instance

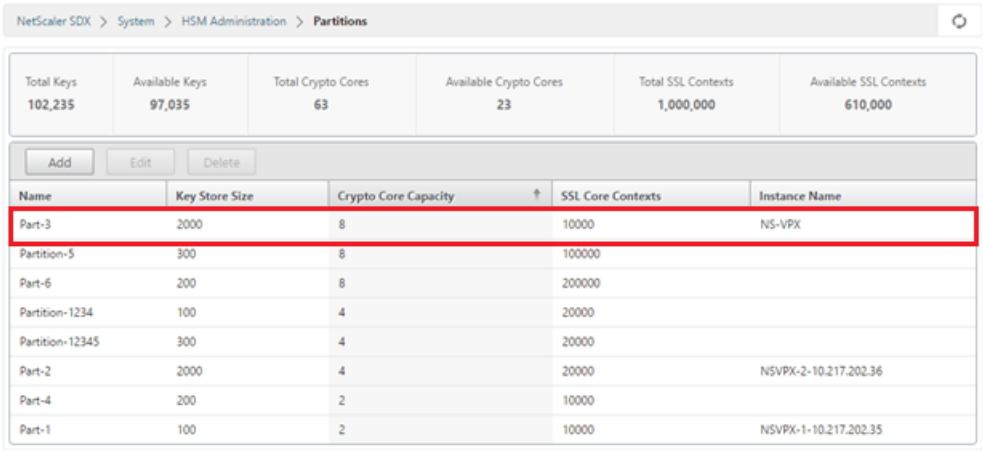
1. On the Configuration tab, navigate to **NetScaler** > **Instances**, and add or modify an instance.
2. Select **Enable FIPS**, and from the **Partitions** list, select a partition to attach to this instance.



You can verify that the partition is attached to an instance by using either the GUI or the CLI.

In the GUI, navigate to **System** > **HSM Administration** > **Partitions**. The instance name attached to the partition is

displayed.



To unassign a FIPS partition¸ navigate to **NetScaler** > **Instances**. Edit the instance and clear the **Enable FIPS** check box.

In the CLI, at the command prompt, type the following commands:

> **show fips**

FIPS Card is not configured

Done

>

If you see the following output, see the troubleshooting section for debugging.

ERROR: Operation not permitted - no FIPS card present in the system

Configuring the HSM for an Instance on an SDX 14030/14060/14080 FIPS Appliance

Jan 04, 2018

You must first check the state of your FIPS card to verify that the driver loaded correctly, and then initialize the card.

At the command prompt, type:

> show fips

FIPS Card is not configured

Done

If the driver is not loaded correctly, the message “ERROR: Operation not permitted - no FIPS card present in the system” appears.

Initializing the FIPS Card

> ### Important
>
> Verify that the /nsconfig/fips directory has successfully been created on the appliance.

Do not save the configuration before you restart the appliance for the third time.

Perform the following steps to initialize the FIPS card:

1. Reset the FIPS card.
2. Restart the appliance.
3. Set the security officer password for partitions 0 and 1, and the user password for partition 1.
   Note: The set or reset command takes more than 60 seconds to run.
4. Save the configuration.
5. Verify that the password encrypted key for the master partition (master_pek.key) has been created in the /nsconfig/fips/ directory.
6. Restart the appliance.
7. Verify that the FIPS card is UP.

Note: From release 11.1 build 56.x, the following message appears when you run the **set fips** command:

This command will erase all data on the FIPS card. You must save the configuration (saveconfig) after executing this command. [Note: On MPX/SDX 14xxx FIPS platform, the FIPS security is at Level-3 by default, and the -initHSM Level-2 option is internally converted to Level-3] Do you want to continue?(Y/N)y

To initialize the FIPS card by using the NetScaler CLI

At the command prompt, type the following commands:

> reset fips

> reboot

> set fips -initHSM Level-2 <soPassword> <oldsoPassword> <userPassword> -hsmLabel <string>

This command will erase all data on the FIPS card. You must save the configuration (saveconfig) after executing this command. [Note: On MPX/SDX 14xxx FIPS platform, the FIPS security is at Level-3 by default, and the -initHSM Level-2 option is internally converted to Level-3] Do you want to continue?(Y/N)y

> saveconfig

> reboot

> show fips

```
> reset fips

 Done

> reboot

> set fips -initHSM Level-2 so12345 so12345 user123 -hsmLabel NSFIPS

This command will erase all data on the FIPS card. You must save the configuration (saveconfig) after executing this command. Do you w

Creating a FIPS Key for an Instance on an SDX 14030/14060/14080 FIPS Appliance

Feb 16, 2017

You can create a FIPS key on your instance or import an existing FIPS key into the instance. An SDX 14030/14060/14080 FIPS appliance supports only 2048-bit and 3072-bit keys and an exponent value of F4. For PEM keys, an exponent is not required. Verify that the FIPS key is created correctly. Create a certificate signing request and a server certificate. Finally, add the certificate-key pair to your instance.

> **Note**
>
> 1024-bit and 4096-bit keys and an exponent value of 3 are not supported.

To create a FIPS key by using the NetScaler command line

At the command prompt, type:

create ssl fipsKey <fipsKeyName> -modulus <positive_integer> [-exponent F4]

```
> create fipsKey  f1 -modulus 2048 -exponent F4

Done
```

To import a FIPS key by using the NetScaler command line

At the command prompt, type:

import ssl fipsKey <fipsKeyName> -key <string> [-inform <inform>] [-wrapKeyName <string>] [-iv<string>] [-exponent F4]

```
>import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform SIM -exponent F4

Done

>import fipskey Key-FIPS-2 -key Key-FIPS-2.key -inform PEM

Done
```

Verify that the FIPS key is created or imported correctly by running the **show fipskey** command.

```
> show fipskey

1)      FIPS Key Name: Key-FIPS-2

Done
```

To create a certificate signing request by using the NetScaler command line

At the command prompt, type:

create ssl certReq <reqFile> (-keyFile <input_filename> | -fipsKeyName <string>) [-keyform (DER | PEM) {-PEMPassPhrase }] -countryName <string> -stateName <string> -organizationName<string> [-organizationUnitName <string>] [-localityName <string>] [-commonName <string>] [-emailAddress <string>] {-challengePassword } [-companyName <string>] [-digestMethod (SHA1 | SHA256)]

```
>create certreq f1.req –fipsKeyName f1 -countryName US -stateName CA -organizationName Citrix -companyName Citrix -commonNam

Done
```

To create a server certificate by using the NetScaler command line

At the command prompt, type:

create ssl cert <certFile> <reqFile> <certType> [-keyFile <input_filename>] [-keyform (DER | PEM) {-PEMPassPhrase }] [-days <positive_integer>] [-certForm (DER | PEM)] [-CAcert <input_filename>] [-CAcertForm (DER | PEM)] [-CAkey <input_filename>] [-CAkeyForm (DER | PEM)] [-CAserial <output_filename>]

```
> create cert f1.cert f1.req SRVR_CERT -CAcert ns-root.cert -CAkey ns-root.key -CAserial ns-root.srl -days 1000

Done
```

The above example creates a server certificate using a local root CA on the appliance.

To add a certificate-key pair by using the NetScaler command line

At the command prompt, type:

add ssl certKey <certkeyName> (-cert <string> [-password]) [-key <string> | -fipsKey <string> | -hsmKey <string>] [-inform <inform>] [-expiryMonitor (ENABLED | DISABLED) [-notificationPeriod <positive_integer>]] [-bundle (YES | NO)]

```
> add certkey cert1 -cert f1.cert -fipsKey f1

Done
```

After creating the FIPS key and server certificate, you can add the generic SSL configuration. Enable the features that are required for your deployment. Add servers, services, and SSL virtual servers. Bind the certificate-key pair and the service to the SSL virtual server, and save the configuration.

```
>enable ns feature SSL LB

Done

>add server s1 10.217.2.5

Done

>add service sr1 s1 HTTP 80

Done

>add lb vserver v1 SSL 10.217.2.172 443

Done

>bind ssl vserver v1 –certkeyName cert1

Done

>bind lb vserver v1 sr1

Done

> saveconfig

Done
```

For information about configuring secure HTTPS and secure RPC, see http://docs.citrix.com/en-us/netscaler/11/getting-started-with-netscaler/configure-fips-first-time.html.

Upgrading the FIPS Firmware on a VPX Instance

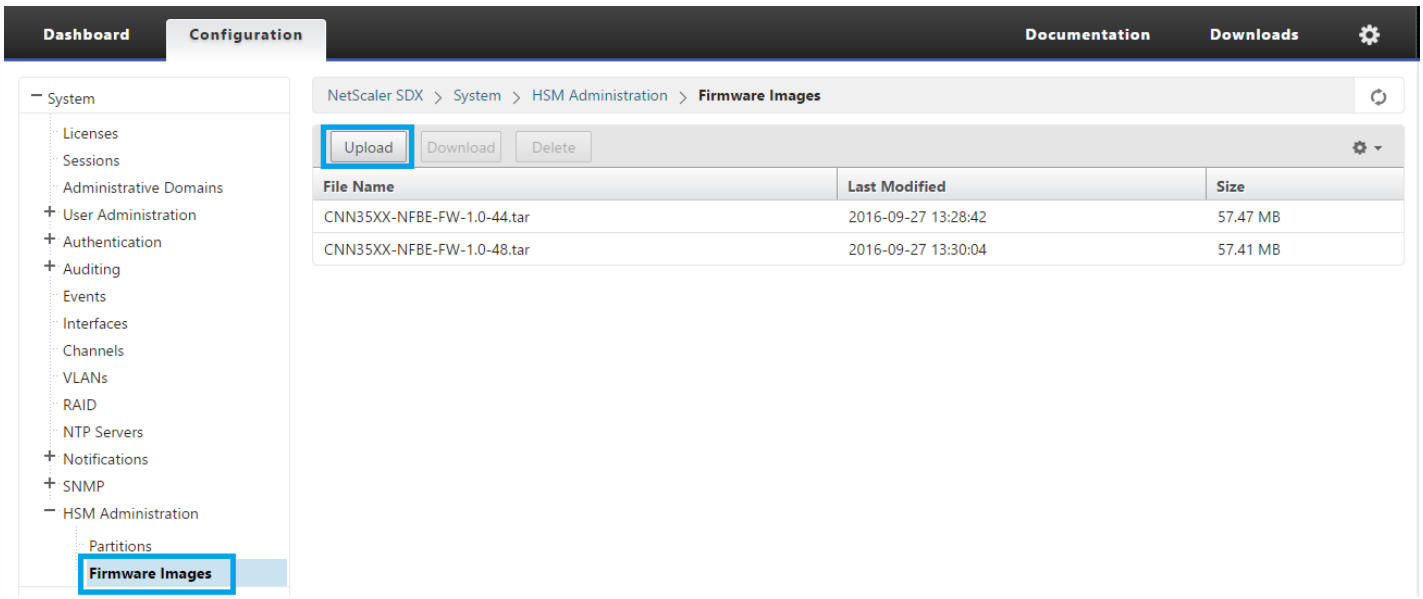
Oct 05, 2016

FIPS firmware updates are released from time to time. Download the latest firmware from the Citrix download page and upload it to the appliance. The upgrade process might take up to 10 minutes to complete. The instance is restarted after the upgrade.

To upgrade the FIPS firmware on a VPX instance

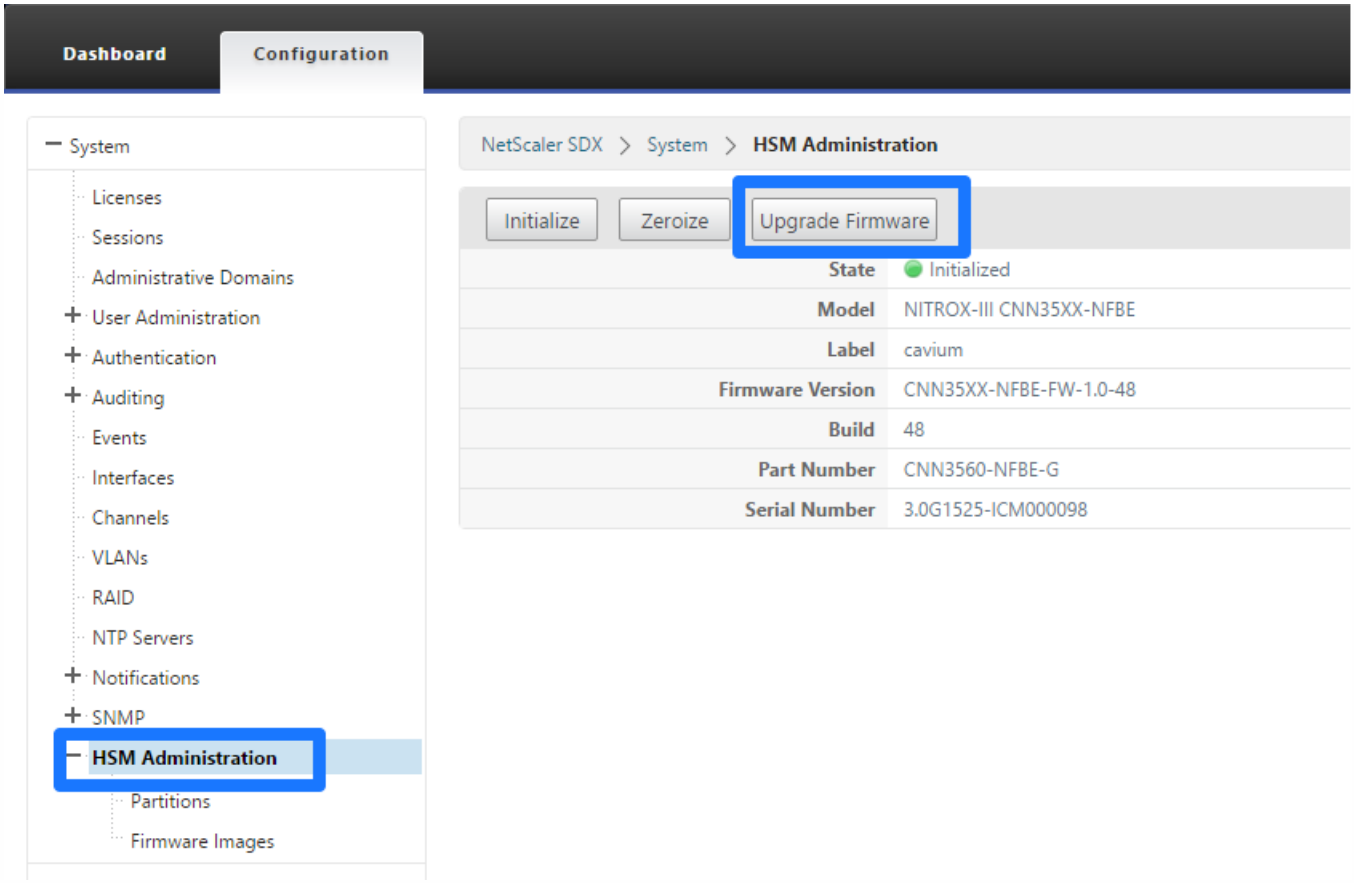
1. Navigate to **System** > **HSM Administration** > **Firmware Images**.

2. Select **Upload**.

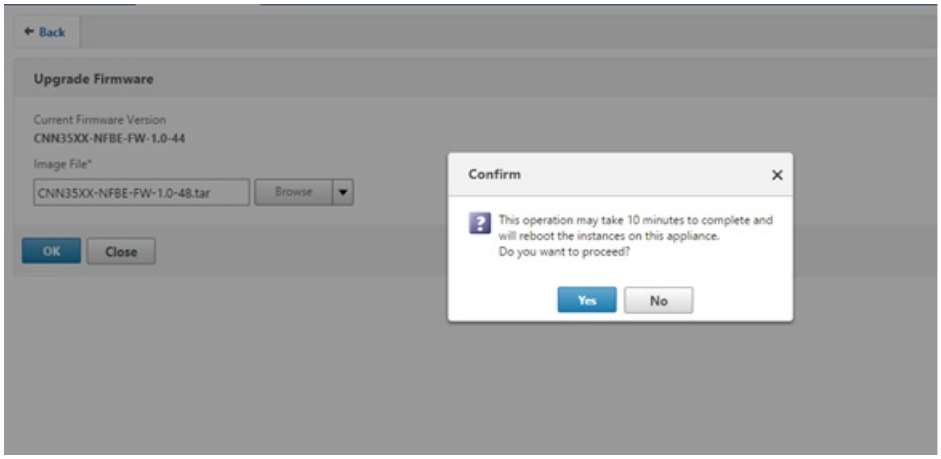


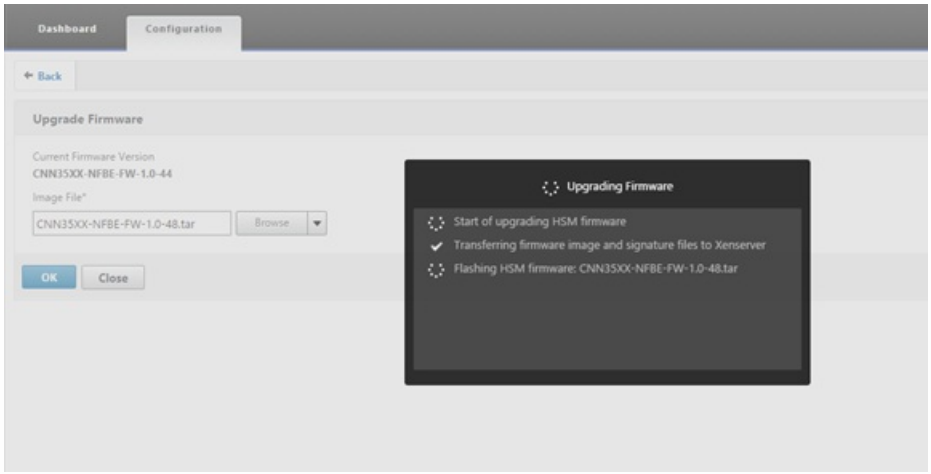
3. Navigate to the folder that contains the firmware image and select the file.

4. Navigate to **System** > **HSM Administration**, and select **Upgrade Firmware**.



5. Select the firmware image to upgrade to, and click **OK**.





Support for a Hybrid FIPS Mode on the MPX/SDX 14000 FIPS Platform

May 18, 2017

> ## Note
>
> - This feature is supported in release 11.1 build 53.x and later.
> - This feature is supported only on the new MPX/SDX 14000 FIPS platform containing one primary FIPS card and one or more secondary cards. It is not supported on a VPX platform or a platform containing only one type of hardware card.

On a FIPS platform, all the encryption and decryption (asymmetric and symmetric) is performed on the FIPS card for security reasons. However, you can perform part of this activity (asymmetric) on a FIPS card and offload the bulk encryption and decryption (symmetric) to another card without compromising the security of your keys.

The new MPX/SDX 14000 FIPS platform contains one primary card and one or more secondary cards. If you enable the hybrid FIPS mode, the pre-master secret decryption commands are run on the primary card because the private key is stored on this card, but the bulk encryption and decryption is offloaded to the secondary card. This significantly increases the bulk encryption throughput on an MPX/SDX 14000 FIPS platform as compared to non-hybrid FIPS mode and the existing MPX 9700/10500/12500/15000 FIPS platform. Enabling the hybrid FIPS mode also improves the SSL transaction per second on this platform.

The hybrid FIPS mode is disabled by default to meet the strict certification requirements where all the crypto-computation must be done inside a FIPS certified module. You must enable the hybrid mode to offload the bulk encryption and decryption to the secondary card.

> ## Note
>
> On an SDX 14000 FIPS platform, you must first assign an SSL chip to the VPX instance before you enable the hybrid mode.

To enable hybrid FIPS mode by using the NetScaler CLI

At the command prompt, type:

set SSL parameter -hybridFIPSMode {ENABLED | DISABLED}

Arguments

hybridFIPSMode

When this mode is enabled, system will use additional crypto hardware to accelerate symmetric crypto operations.

Possible values: ENABLED, DISABLED

Default value: DISABLED

```
set SSL parameter -hybridFIPSMode ENABLED

> show SSL parameter

Advanced SSL Parameters

----------------------

. . . . . .

Hybrid FIPS Mode    : ENABLED

. . . . . .

Done

>
```

To enable hybrid FIPS mode by using the NetScaler GUI

1. Navigate to **Traffic Management** > **SSL**.
2. In the details pane, under **Settings**, click **Change advanced SSL settings**.
3. In the **Change Advanced SSL Settings** dialog box, select **Hybrid FIPS Mode**.

Limitations

1. Renegotiation is not supported.

2. The “stat ssl parameter” command on an SDX 14000 platform does not display the correct secondary card utilization percentage. It always displays 0.00% utilization.

```
> stat ssl

SSL Summary

# SSL cards present                    1

# SSL cards UP                         1

# Secondary SSL cards present          4
```

# Secondary SSL cards UP	4
SSL engine status	1
SSL sessions (Rate)	963
Secondary card utilization (%)	0.00

Support for Thales nShield® HSM

Feb 13, 2017

Note: This feature is available from release 11, build 62.10.

A non-FIPS NetScaler appliance stores the server's private key on the hard disk. On a FIPS appliance, the key is stored in a cryptographic module known as hardware security module (HSM). Storing a key in the HSM protects it from physical and software attacks. In addition, the keys are encrypted by using special FIPS approved ciphers.

Only the NetScaler MPX 9700/10500/12500/15500 FIPS appliances support a FIPS card. Support for FIPS is not available on other MPX appliances, or on the SDX and VPX appliances. This limitation is addressed by supporting a Thales nShield® Connect external HSM on all NetScaler MPX, SDX, and VPX appliances except the MPX 9700/10500/12500/15500 FIPS appliances.

Thales nShield Connect is an external FIPS-certified network-attached HSM. With a Thales HSM, the keys are securely stored as application key tokens on a remote file server (RFS) and can be reconstituted inside the Thales HSM only.

If you are already using a Thales HSM, you can now use a NetScaler ADC to optimize, secure, and control the delivery of all enterprise and cloud services.

Note:

- Thales HSMs comply with FIPS 140-2 Level 3 specifications, while the MPX FIPS appliances comply with level 2 specifications.
- You cannot decrypt the trace while using the Thales HSM, because the response from the HSM to the NetScaler appliance is encrypted and only the Hardserver can read it.

NetScaler Version	Software Appliance Version	Firmware Version	Client Version
11.1, 12.0	5.2.3-1	6.2.1	6.0.0
11.1, 12.0	6.2.2-5	6.10.9	6.2.2

This section includes the following details:

- Architecture Overview
- Prerequisites
- Configuring the ADC-Thales Integration
- Limitations
- Appendix

Architecture Overview

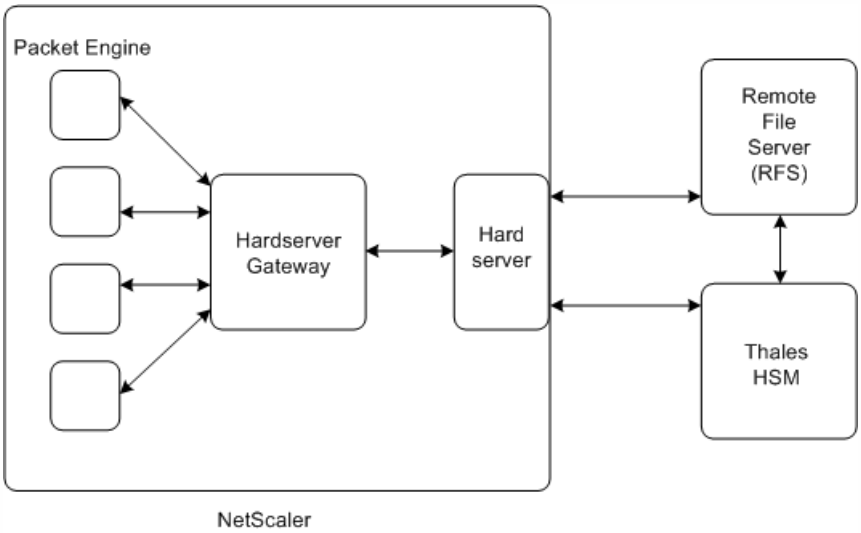
Aug 17, 2015

The three entities that are part of a NetScaler-Thales deployment are a Thales nShield Connect module, a remote file server (RFS), and a NetScaler ADC.

The Thales nShield Connect is a network-attached hardware security module. The RFS is used to configure the HSM and to store the encrypted key files.

Hardserver, a proprietary daemon provided by Thales, is used for communication between the client (ADC), the Thales HSM, and the RFS. It uses the IMPATH secure communication protocol. A gateway daemon, called the Hardserver Gateway, is used to communicate between the NetScaler packet engine and the Hardserver.

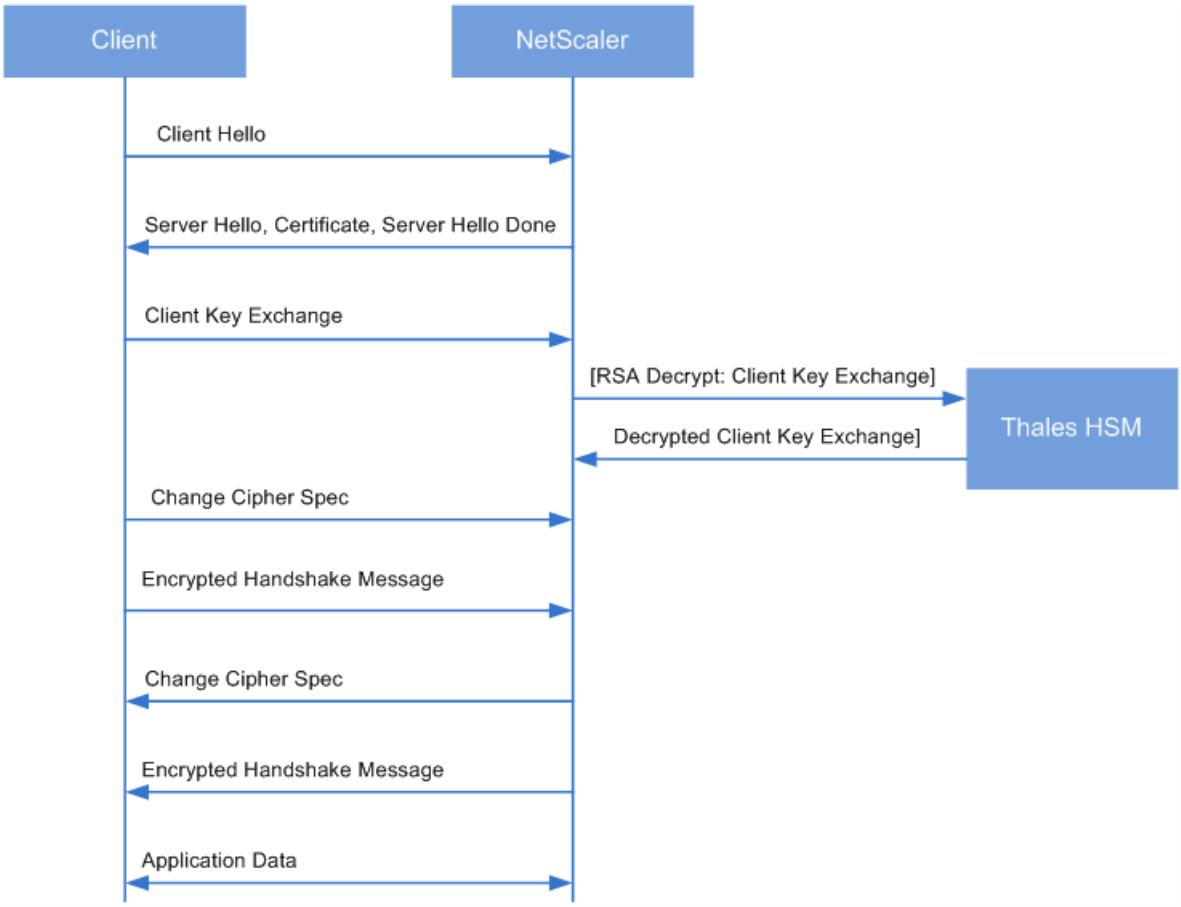
Note: The terms Thales nShield Connect, Thales HSM, and HSM are used interchangeably in this documentation.
The following figure illustrates the interaction between the different components.



In a typical deployment, the RFS is used to securely store keys generated by the HSM. After the keys are generated, you can securely transfer them to the ADC and then use the NetScaler configuration utility or command line to load the keys to the HSM. A virtual server on the ADC uses Thales to decrypt the client key exchange to complete the SSL handshake. Thereafter, all the SSL operations are performed on the ADC.

Note: The terms keys and application key tokens are used interchangeably in this documentation.
The following figure illustrates the packet flow in the SSL handshake with the Thales HSM.

Figure 1. SSL Handshake Packets Flow Diagram with NetScaler Using Thales HSM



Note: The communication between the ADC and the HSM uses a Thales proprietary communication protocol, called IMPATH.

Prerequisites

Aug 17, 2015

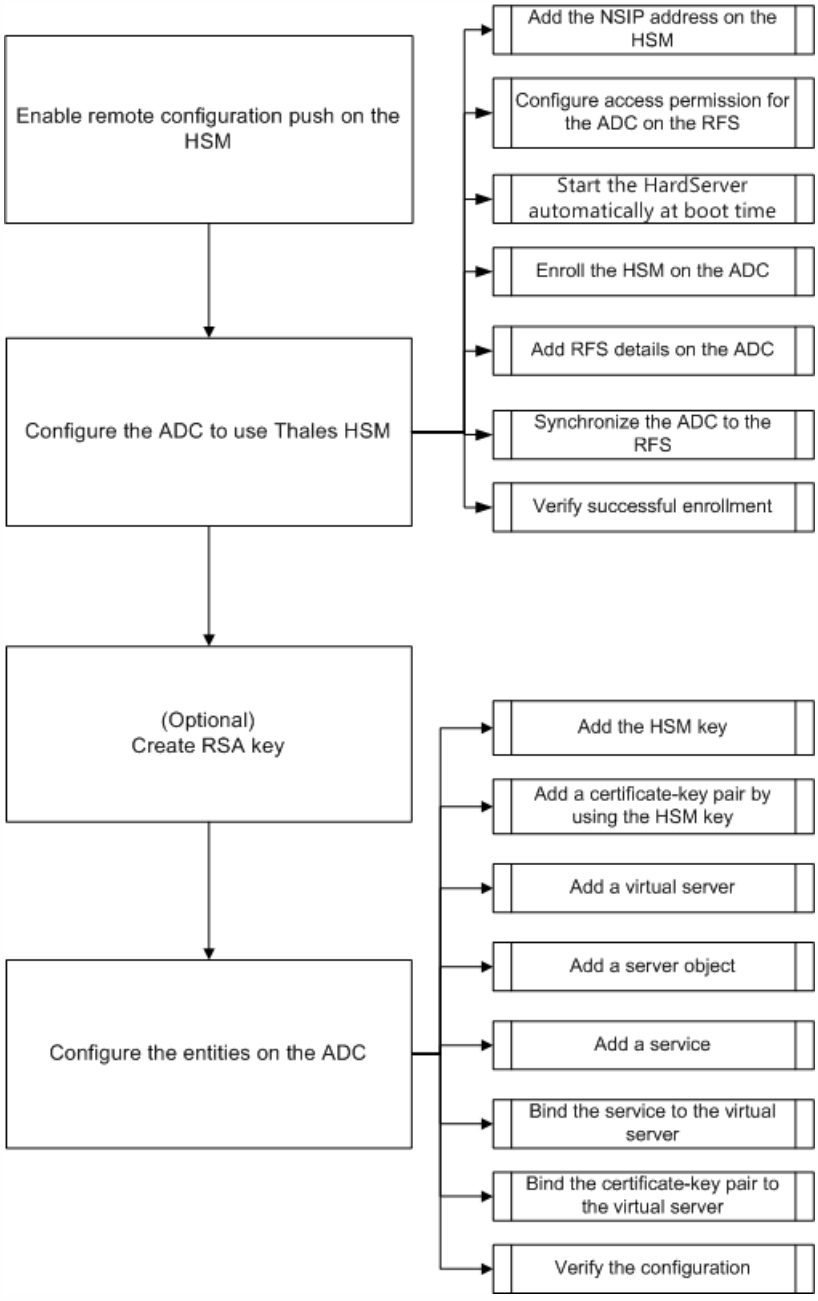
Before you can use a Thales nShield Connect with a NetScaler ADC, make sure that the following prerequisites are met:

- A Thales nShield Connect device is installed in the network, ready to use, and accessible to the NetScaler ADC. That is, the NetScaler IP (NSIP) address is added as an authorized client on the HSM.
- A usable Security World exists. Security World is a unique key management architecture used by the Thales nShield line of HSMs. It protects and manages keys as application key tokens, enabling unlimited key capacity, and automatic key backup and recovery. For more information about creating a Security World, see the nShield Connect Quick Start Guide from Thales. You can also find the guide in the CD provided with the Thales HSM module at CipherTools-linux-dev-xx.xx.xx/document/nShield_Connect_Quick_Start_Guide.pdf.
  Note: Softcard or token/OCS protected keys are currently not supported on the NetScaler ADC.
- Licenses are available to support the number of clients that will be connected to the Thales HSM. The ADC and RFS are clients of the HSM.
- A remote file server (RFS) is installed in the network and is accessible to the NetScaler ADC.
- The Thales nShield Connect device, the RFS, and the NetScaler ADC can initiate connections with each other through port 9004.
- You are using NetScaler release 10.5 build 52.1115.e or later.
- The NetScaler appliance does not contain a FIPS Cavium card.
  Important: Thales HSM is not supported on the MPX 9700/10500/12500/15500 FIPS appliances.

Configuring the ADC-Thales Integration

Feb 13, 2017

The following flowchart depicts the tasks that you need to perform to use Thales HSM with a NetScaler ADC:



As shown in the above flowchart, you perform the following tasks:

1. Enable remote configuration push on the HSM.
2. Configure the ADC to use the Thales HSM.
   - Add the NSIP address on the HSM.
   - Configure access permission for the ADC on the RFS.
   - Configure automatic start of the Hardserver at boot time.

- Enroll the HSM on the ADC.
- Add RFS details on the ADC.
- Synchronize the ADC to the RFS.
- Verify that Thales HSM is successfully enrolled on the ADC.

3. (Optional) Create an HSM RSA key.
4. Configure the entities on the NetScaler ADC.
   - Add the HSM key.
   - Add a certificate-key pair by using the HSM key.
   - Add a virtual server.
   - Add a server object.
   - Add a service.
   - Bind the service to the virtual server.
   - Bind the certificate-key pair to the virtual server.
   - Verify the configuration.

You must specify the IP address of the RFS on the Thales HSM so that it accepts the configuration that the RFS pushes to it. Use the nShield Connect front panel on the Thales HSM to perform the following procedure.

To specify the IP address of a remote computer on the Thales HSM

1. Navigate to System Configuration > Config file options > Allow auto push.
2. Select ON, and specify the IP address of the computer (RFS) from which to accept the configuration.

You must specify the IP address of the RFS on the Thales HSM so that it accepts the configuration that the RFS pushes to it. Use the nShield Connect front panel on the Thales HSM to perform the following procedure.

To specify the IP address of a remote computer on the Thales HSM

1. Navigate to System Configuration > Config file options > Allow auto push.
2. Select ON, and specify the IP address of the computer (RFS) from which to accept the configuration.

Sample values used in this documentation:

NSIP address=10.217.2.43

Thales HSM IP address=10.217.2.112

RFS IP address=10.217.2.6

Add the NetScaler IP (NSIP) Address on the HSM

Typically you use the nShield Connect front panel to add clients to the HSM. For more information, see the nShield Connect Quick Start Guide.
Alternately, use the RFS to add the ADC as a client to the HSM. To do this, you must add the NSIP address in the HSM configuration on the RFS, and then push the configuration to the HSM. Before you can do this, you must know the electronic serial number (ESN) of the HSM.

To get the ESN of your HSM, run the following command on the RFS:

root@ns# /opt/nfast/bin/anonkneti <Thales HSM IP address>

Example
root@ns# /opt/nfast/bin/anonkneti 10.217.2.112
BD17-C807-58D9 5e30a698f7bab3b2068ca90a9488dc4e6c78d822
The ESN number is BD17-C807-58D9.

After you have the ESN number, use an editor, such as vi, to edit the HSM configuration file on the RFS.

vi /opt/nfast/kmdata/hsm-BD17-C807-58D9/config/config

In the hs_clients section, add the following entries:

# Amount of data in bytes to encrypt with a session key before session key# renegotiation, or 0 for unlimitied. (default=1024*1024*8b=8Mb).
# datalimit=INT
addr=10.217.2.43
clientperm=unpriv
keyhash=0000000000000000000000000000000000000000
esn=
timelimit=86400
datalimit=8388608

Note: Include one or more hyphens as delimiters to add multiple entries in the same section.
To push the configuration to the HSM, run the following command on the RFS:

/opt/nfast/bin/cfg-pushnethsm --address=<Thales HSM IP address> --force /opt/nfast/kmdata/hsm-BD17-C807-58D9/config/config

Example
/opt/nfast/bin/cfg-pushnethsm --address=10.217.2.112 --force
/opt/nfast/kmdata/hsm-BD17-C807-58D9/config/config

Configure Access Permission for the ADC on the RFS

To configure access permission for the ADC on the RFS, run the following command on the RFS:
/opt/nfast/bin/rfs-setup --force -g --write-noauth <NetScaler IP address>

Example
[root@localhost bin]# /opt/nfast/bin/rfs-setup --force -g --write-noauth 10.217.2.43
Adding read-only remote_file_system entries
Ensuring the directory /opt/nfast/kmdata/local exists
Adding new writable remote_file_system entries
Ensuring the directory /opt/nfast/kmdata/local/sync-store exists
Saving the new config file and configuring the hardserver
Done
Verify that the ADC can reach both the RFS and Thales HSM by using port 9004.

Configure Automatic Start of the Hardserver at Boot Time

Create a file and then restart the appliance. Now, whenever you restart the appliance, and if this file is found, the Hardserver is automatically started.

At the shell prompt, type:
touch /var/opt/nfast/bin/thales_hsm_is_enrolled

At the command prompt, type:
reboot

Enroll the HSM on the ADC

Change directory to /var/opt/nfast/bin.
To add HSM details into the ADC configuration, run the following command on the ADC:

nethsmenroll --force <Thales_nShield_Connect_ip_address> $(anonkneti <Thales_nShield_Connect_ip_address>)

Example
root@ns# ./nethsmenroll --force 10.217.2.112 $(anonkneti 10.217.2.112)

OK configuring hardserver's nethsm imports
This step adds the following entries after the line # ntoken_esn=ESN in the nethsm_imports section of the /var/opt/nfast/kmdata/config/config file.

…
local_module=0
remote_ip=10.217.2.112
remote_port=9004
remote_esn=BD17-C807-58D9
keyhash=5e30a698f7bab3b2068ca90a9488dc4e6c78d822
timelimit=86400
datalimit=8388608
privileged=0
privileged_use_high_port=0
ntoken_esn=
Change directory to /var/opt/nfast/bin and run the following command on the ADC:
touch "thales_hsm_is_enrolled"
Note: To remove an HSM that is enrolled on the ADC, type: ./nethsmenroll –-remove <NETHSM-IP>

Add RFS details on the ADC

To add RFS details, change directory to /var/opt/nfast/bin/ and then run the following command:
./rfs-sync --no-authenticate --setup <rfs_ip_address>

Example
./rfs-sync --no-authenticate --setup 10.217.2.6
No current RFS synchronization configuration.
Configuration successfully written; new config details:
Using RFS at 10.217.2.6:9004: not authenticating.
This step adds the following entries after the # local_esn=ESN line in the rfs_sync_client section of the /var/opt/nfast/kmdata/config/config file.

……
remote_ip=10.217.2.6
remote_port=9004
use_kneti=no
local_esn=
Note: To remove an RFS that is enrolled on the ADC, type: ./rfs_sync –remove
Example
./rfs-sync --no-authenticate --setup 10.217.2.6
No current RFS synchronization configuration.
Configuration successfully written; new config details:
Using RFS at 10.217.2.6:9004: not authenticating.
This step adds the following entries after the # local_esn=ESN line in the rfs_sync_client section of the /var/opt/nfast/kmdata/config/config file.

……
remote_ip=10.217.2.6
remote_port=9004
use_kneti=no
local_esn=

Synchronize the ADC to the RFS

To synchronize all the files, change directory to /var/opt/nfast/bin and then run the following command on the ADC:
./rfs-sync –-update

This command fetches all the World files, module files, and key files from the /opt/nfast/kmdata/local directory on the RFS and puts them into the /var/opt/nfast/kmdata/local directory on the ADC. Citrix recommends that you manually copy the World files, the module_XXXX_XXXX_XXXX files, where XXXX_XXXX_XXXX is the ESN of the enrolled HSM, and only the required RSA key and certificate files.

Verify that the Thales HSM is successfully enrolled on the ADC

After you synchronize the ADC to the RFS, do the following:

- Verify that the local Hardserver is UP and running. (nCipher server running).
- Get the state of the configured HSMs, and verify that the values for the n_modules (number of modules) field and the km info fields are non-zero.
- Verify that the HSM is enrolled correctly and is usable (state 0x2 Usable) by the ADC.

- Load tests using sigtest run properly.

Change directory to /var/opt/nfast/bin, and at the shell prompt, run the following commands:
root@ns# ./chkserv root@ns# ./nfkminfo root@ns# ./sigtest
See Appendix for an example.

Only RSA keys are supported as HSM keys.

Note: Skip this step if keys are already present in the /opt/nfast/kmdata/local folder on the RFS.
Create an RSA key, a self-signed certificate, and a Certificate Signing Request (CSR). Send the CSR to a certificate authority to get a server certificate.

The following files are created in the example below:
- Embed RSA key: key_embed_2ed5428aaeae1e159bdbd63f25292c7113ec2c78
- Self-Signed Certificate: example_selfcert
- Certificate Signing Request: example_req

Note: The generatekey command is supported in strict FIPS 140-2 Level 3 Security World. An administrator card set (ACS) or an operator card set (OCS) is needed to control many operations, including the creation of keys and OCSs. When you run the generatekey command, you are prompted to insert an ACS or OCS card. For more information about strict FIPS 140-2 Level 3 Security World, see the nShield Connect User Guide.
The following example uses Level-2 Security World. In the example, the commands are in boldface type.

Example

```
[root@localhost bin]# ./generatekey embed
size: Key size? (bits, minimum 1024) [1024] > 2048
OPTIONAL: pubexp: Public exponent for RSA key (hex)? []
>
embedsavefile: Filename to write key to? []
> example
plainname: Key name? [] > example
x509country: Country code? [] > US
x509province: State or province? [] > CA
x509locality: City or locality? [] > Santa Clara
x509org: Organisation? [] > Citrix
x509orgunit: Organisation unit? [] > NS
x509dnscommon: Domain name? [] > www.citrix.com
x509email: Email address? [] > example@citrix.com
nvram: Blob in NVRAM (needs ACS)? (yes/no) [no] >
digest: Digest to sign cert req with? (md5, sha1, sha256, sha384, sha512)
 [default sha1] > sha512
key generation parameters:
 operation     Operation to perform            generate
 application   Application                     embed
 verify        Verify security of key          yes
 type          Key type                        RSA
 size          Key size                        2048
 pubexp        Public exponent for RSA key (hex)
 embedsavefile  Filename to write key to       example
 plainname     Key name                        example
```

```
x509country    Country code                  US
x509province   State or province              CA
x509locality   City or locality              Santa Clara
x509org        Organisation                  Citrix
x509orgunit    Organisation unit             NS
x509dnscommon  Domain name                   www.citrix.com
x509email      Email address                 example@citrix.com
nvram          Blob in NVRAM (needs ACS)     no
digest         Digest to sign cert req with  sha512
Key successfully generated.
Path to key: /opt/nfast/kmdata/local/key_embed_2ed5428aaeae1e159bdbd63f25292c7113ec2c78
You have new mail in /var/spool/mail/root
```

Result

You have created a CSR (example_req), a self-signed certificate (example_selfcert), and an application key token file in embed format (/opt/nfast/kmdata/local/key_embed_2ed5428aaeae1e159bdbd63f25292c7113ec2c78)

Because the ADC supports keys in simple format only, you must convert the embed key to a simple key.

To convert the embed key to a simple key, run the following command on the RFS:

```
[root@localhost bin]# ./generatekey -r simple
from-application: Source application? (embed, simple) [embed] > embed
from-ident: Source key identifier? (c6410ca00af7e394157518cb53b2db46ff18ce29,
                        2ed5428aaeae1e159bdbd63f25292c7113ec2c78)
  [default c6410ca00af7e394157518cb53b2db46ff18ce29]
> 2ed5428aaeae1e159bdbd63f25292c7113ec2c78
ident: Key identifier? [] > examplersa2048key
plainname: Key name? [] > examplersa2048key
key generation parameters:
 operation        Operation to perform    retarget
 application      Application             simple
 verify           Verify security of key  yes
 from-application  Source application     embed
 from-ident       Source key identifier   2ed5428aaeae1e159bdbd63f25292c7113ec2c78
 ident            Key identifier          examplersa2048key
 plainname        Key name                examplersa2048key
Key successfully retargetted.
Path to key: /opt/nfast/kmdata/local/key_simple_examplersa2048key
```

> **Important**
>
> When prompted for the source key identifier, enter **`2ed5428aaeae1e159bdbd63f25292c7113ec2c78`** as the embed key.

Result

A key with the prefix key_simple (for example key_simple_examplersa2048key) is created.

Note: examplersa2048key is the key identifier (ident) and is referred to as the HSM key name on the ADC. A key identifier is unique. All the simple files have the prefix key_simple.

Before the ADC can process traffic, you must do the following:

1. Enable features.
2. Add a subnet IP (SNIP) address.
3. Add the HSM key to the ADC.
4. Add a certificate-key pair by using the HSM key.
5. Add a virtual server.
6. Add a server object.
7. Add a service.
8. Bind the service to the virtual server.
9. Bind the certificate-key pair to the virtual server.
10. Verify the configuration.

Enable features on the ADC

Licenses must be present on the ADC before you can enable a feature.

To enable a feature by using the command line

At the command prompt, run the following commands:

- enable feature lb
- enable feature ssl

To enable a feature by using the configuration utility

Navigate to System > Settings and, in the Modes and Features group, select Configure basic features, and then select SSL Offloading.

Add a subnet IP address

For more information about subnet IP addresses, see Configuring Subnet IP Addresses.

To add a SNIP address and verify the configuration by using the command line

At the command prompt, run the following commands:

- add ns ip <IPAddress> <netmask> -type SNIP
- show ns ip

Example

```
> add ns ip 192.168.17.253 255.255.248.0 -type SNIP
Done
> show ns ip
     Ipaddress       Traffic Domain  Type          Mode     Arp     Icmp     Vserver  State
     ---------       --------------  ----          ----     ---     ----     -------  ------
1)   192.168.17.251   0              NetScaler IP  Active   Enabled  Enabled  NA       Enabled
2)   192.168.17.252   0              VIP           Active   Enabled  Enabled  Enabled  Enabled
3)   192.168.17.253   0              SNIP          Active   Enabled  Enabled  NA       Enabled
 Done
```

To add a SNIP address and verify the configuration by using the configuration utility

Navigate to System > Network > IPs, add an IP address, and select the IP Type as Subnet IP.

Copy the HSM key and certificate to the ADC

Use a secure file transfer utility to securely copy the key (key_simple_examplersa2048key) to the /var/opt/nfast/kmdata/local folder, and the certificate (example_selfcert) to the /nsconfig/ssl folder on the ADC.

Add the key on the ADC

All the keys have a key-simple prefix. When adding the key to the ADC, use the ident as the HSM key name. For example, if the key that you added is key_simple_XXXX, the HSM key name is XXXX.
Important:

- The HSM key name must be the same as the ident that you specified when you converted an embed key to a simple key format.
- The keys must be present in the /var/opt/nfast/kmdata/local/ directory on the ADC.

To add an HSM key by using the command line

At the shell prompt, run the following command:

add ssl hsmKey <hsmKeyName> -key <string>

Example

```
> add ssl hsmKey examplersa2048key –key key_simple_examplersa2048key
Done
```

To add an HSM key by using the configuration utility

Navigate to Traffic Management > SSL > HSM, and add an HSM key.

Add a certificate-key pair on the ADC

For information about certificate-key pairs, see Adding or Updating a Certificate-Key Pair.

To add a certificate-key pair by using the command line

At the command prompt, run the following command:

add ssl certKey <certkeyName> -cert <string> -hsmKey <string>

Example

```
> add ssl certKey key22 -cert example_selfcert -hsmKey examplersa2048key
Done
```

To add a certificate-key pair by using the configuration utility

Navigate to Traffic Management > SSL > Certificates, and add a certificate-key pair.

Add a virtual server

For information about a virtual server, see Configuring an SSL-Based Virtual Server.

To configure an SSL-based virtual server by using the command line

At the command prompt, run the following command:

add lb vserver <name> <serviceType> <IPAddress> <port>

Example
> add lb vserver v1 SSL 192.168.17.252 443
To configure an SSL-based virtual server by using the configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Servers, create a virtual server, and specify the protocol as SSL.

Add a server object

Before you can add a server object on the ADC, make sure that you have created a backend server. The following example uses the built-in python HTTP Server module on a Linux system.
Example

%python –m SimpleHTTPServer 80

To add a server object by using the command line

At the command prompt, run the following command:

add server <name> <IPAddress>

Example
> add server s1 192.168.17.246
To add a server object by using the configuration utilty

Navigate to Traffic Management > Load Balancing > Servers, and add a server.

Add a service

For more information, see Configuring Services.
To configure a service by using the command line

At the command prompt, run the following command:

add service <name> <serverName> <serviceType> <port>

Example
> add service sr1 s1 HTTP 80
To configure a service by using the configuration utility

Navigate to Traffic Management > Load Balancing > Services, and create a service.

Bind the service to the virtual server

For more information, see Binding Services to an SSL-Based Virtual Server.
To bind a service to a virtual server by using the command line

At the command prompt, run the following command:

bind lb vserver <name> <serviceName>

Example
> bind lb vserver v1 sr1
To bind a service to a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open a virtual server, and click in the Services pane to bind a service to the virtual server.

Bind the certificate-key pair to the virtual server on the ADC

For more information, see Binding the Certificate-Key Pair to the SSL-Based Virtual Server.

To bind a certificate-key pair to a virtual server by using the command line

At the command prompt, run the following command:

bind ssl vserver <vServerName> -certkeyName <string>

Example

```
> bind ssl vserver v1 -certkeyName key22
Warning: Current certificate replaces the previous binding
```

To bind a certificate-key pair to a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. Open an SSL virtual server and, in Advanced Settings, click SSL Certificate.
3. Bind a server certificate to the virtual server.

Verify the configuration

To view the configuration by using the command line

At the command prompt, run the following commands:

- show lb vserver <name>
- show ssl vserver <vServerName>

Example

```
> show lb vserver v1
    v1 (192.168.17.252:443) - SSL   Type: ADDRESS
    State: UP
    Last state change was at Wed Oct 29 03:11:11 2014
    Time since last state change: 0 days, 00:01:25.220

1)      CertKey Name: key22       Server Certificate

1)      Cipher Name: DEFAULT
        Description: Predefined Cipher Alias
 Done
```

To view the configuration by using the configuration utility

Navigate to Traffic Management > Load Balancing > Virtual Servers, and double-click an SSL virtual server to open it and view the configuration.

Limitations

Jan 25, 2017

- SSL version 3 (SSLv3) is not supported on an MPX appliance but is supported on a VPX virtual appliance. A VPX instance provisioned on an SDX appliance supports SSLv3 only if an SSL chip is not assigned to the instance.
- ECDHE/DHE ciphers and Export ciphers are not supported.
- SSL server key exchange using HSM keys is not supported.
- If you have added or removed keys after you last saved the configuration, you must save the configuration before you perform a warm restart. If you do not save the configuration, there will be a key mismatch between the ADC and the HSM.
- You cannot bind an HSM key to a DTLS virtual server.
- You cannot bind a certificate-key pair that is created by using an HSM key to an SSL service.
- You cannot use the NetScaler configuration utility to enroll the ADC as a client of the HSM or check the status of the HSM from the configuration utility.
- From release 11 build 62.x, SSL renegotiation is supported.
- You cannot sign OCSP requests by using a certificate-key pair that is created by using an HSM key.
- A certificate bundle with HSM keys is not supported.
- An error does not appear if the HSM key and certificate do not match. Therefore, while adding a certificate-key pair, you need to make sure that the HSM key and certificate match.
- Clustering and admin partitions are not supported.

Support for SafeNet Network Hardware Security Module

Feb 13, 2017

A non-FIPS NetScaler appliance stores the server's private key on the hard disk. On a FIPS appliance, the key is stored in a cryptographic module known as a hardware security module (HSM). Storing a key in the HSM protects it from physical and software attacks. In addition, the keys are encrypted with special FIPS approved ciphers.

Only the NetScaler MPX 9700/10500/12500/15500 FIPS appliances and the MPX/SDX 14000 FIPS appliances support a FIPS card. Support for FIPS is not available on other MPX/SDX appliances, or on the NetScaler VPX appliances. This limitation is addressed by supporting a SafeNet network HSM on all NetScaler MPX, SDX, and VPX appliances except the MPX 9700/10500/12500/15500 FIPS and the MPX 14000/SDX FIPS appliances.

A SafeNet network HSM is designed to protect critical cryptographic keys and to accelerate sensitive cryptographic operations across a wide range of security applications.

Supported Versions Matrix

NetScaler Version	Software Appliance Version	Firmware Version	Client Version
11.1, 12.0	5.2.3-1	6.2.1	6.0.0
11.1, 12.0	6.2.2-5	6.10.9	6.2.2

Prerequisites

Jul 28, 2016

Before you can use a SafeNet network HSM with a NetScaler ADC, make sure that the following prerequisites are met:

- A SafeNet network HSM is installed in the network, ready to use, and accessible to the NetScaler ADC. That is, the NetScaler IP (NSIP) address is added as an authorized client on the HSM.
- Licenses are available to support the required number of partitions on the HSM.
- The SafeNet network HSM and the NetScaler ADC can initiate connections with each other through port 1792.
- You are using NetScaler release 11.1.
- The NetScaler appliance does not contain a FIPS Cavium card.

> **Important**
>
> SafeNet network HSMs are not supported on the MPX 9700/10500/12500/15500 FIPS appliances.

Configuring a SafeNet Client on the NetScaler ADC

Aug 10, 2017

After you have configured the SafeNet HSM and created the required partitions, you must create clients and assign them to partitions. Begin by configuring the SafeNet clients on the NetScaler ADC and setting up the network trust links (NTLs) between the SafeNet clients and the SafeNet HSM. A sample configuration is given in the Appendix.

1) Change directory to /var/safenet and install the Safenet client. At the shell prompt, type:

cd /var/safenet

To install Safenet client version 6.0.0, type:

install_client.sh -v 600

To install Safenet client version 6.2.2, type:

install_client.sh -v 622

> **Note**
>
> SafeNet client version 6.2.2 is supported in release 11.1 build 54.x and later.

2) Configure the NTLs between SafeNet client (ADC) and HSM.

After the "/var/safenet/" directory is created, perform the following tasks on the ADC.

a) Change directory to /var/safenet/config/ and run the "safenet_config" script. At the shell prompt, type:

cd /var/safenet/config

sh safenet_config

This script copies the "Chrystoki.conf" file into the /etc/ directory. It also generates a symbolic link "libCryptoki2_64.so" in the "/usr/lib/" directory.

b) Create and transfer a certificate and key between the ADC and the SafeNet HSM.

In order to communicate securely, the ADC and the HSM must exchange certificates. Create a certificate and key on the ADC and then transfer it to the HSM. Copy the HSM certificate to the ADC.

i) Change directory to /var/safenet/safenet/lunaclient/bin.

ii) Create a certificate on the ADC. At the shell prompt, type:

./vtl createCert -**n** <ip address of NetScaler>

This command also adds the certificate and key path to the "/etc/Chrystoki.conf" file.

iii) Copy this certificate to the HSM. At the shell prompt, type:

scp /var/safenet/safenet/lunaclient/cert/client/<ip address of NS>**.pem** <LunaSA_HSM account>@<IP address of Luna SA>

iv) Copy the HSM certificate to the NetScaler ADC. At the shell prompt, type:

scp <HSM account>@<HSM IP>**:server.pem /var/safenet/safenet/lunaclient/server_**<HSM ip>.pem

3) Register the NetScaler ADC as a client and assign it a partition on the SafeNet HSM.

Log on to the HSM and create a client. Enter the NSIP as the client IP. This must be the IP address of the ADC from which you transferred the certificate to the HSM. After the client is successfully registered, assign a partition to it. Run the following commands on the HSM.

a) Use SSH to connect to the SafeNet HSM and enter the password.

b) Register the NetScaler ADC on the SafeNet HSM. The client is created on the HSM. The IP address is the client's IP address. That is, the NSIP address.

At the prompt, type:

client register –client <client name> **-ip** <netscaler ip>

c) Assign the client a partition from the partition list. To view the available partitions, type:

<luna_sh> **partition list**

Assign a partition from this list. Type:

<lunash:> **client assignPartition -client** <Client Name> **-par** <Partition Name>

4) Register the HSM with its certificate on the NetScaler ADC.

On the ADC, change directory to "/var/safenet/safenet/lunaclient/bin" and, at the shell prompt, type:

./vtl addserver -n <IP addr of HSM> **-c /var/safenet/safenet/lunaclient/server_**<HSM_IP>**.pem**

To remove the HSM that is enrolled on the ADC, type:

./vtl deleteServer -n <HSM IP> **-c** <cert path>

To list the HSM servers configured on the ADC, type:

./vtl listServer

> ## Note
>
> Before removing the HSM by using vtl, make sure all the keys for that HSM are manually removed from the appliance. HSM keys cannot be deleted after the HSM server is removed.

5) Verify the network trust links (NTLs) connectivity between the ADC and HSM. At the shell prompt, type:

./vtl verify

If verification fails, review all the steps. Errors are generally due to an incorrect IP address in the client certificates.

6) Save the configuration.

The above steps update the "/etc/Chrystoki.conf" configuration file. This file is deleted when the ADC is started. Copy the configuration to the default configuration file, which is used when an ADC is restarted.

At the shell prompt, type:

root@ns# **cp /etc/Chrystoki.conf /var/safenet/config/**

Recommended practice is to run this command every time there is a change to the SafeNet-related configuration.

7) Start the SafeNet gateway process.

At the shell prompt, type:

sh /var/safenet/gateway/start_safenet_gw

8) Configure automatic start of the gateway daemon at boot time.

Create the "safenet_is_enrolled" file, which indicates that SafeNet HSM is configured on this ADC. Whenever the ADC restarts and this file is found, the gateway is automatically started.

At the shell prompt, type:

touch /var/safenet/safenet_is_enrolled

Additional NetScaler Configuration

Jun 23, 2016

1) Generate a key on the HSM.
Use third party tools to create keys on the HSM.

2) Add an HSM key on the ADC.

Important! The # character is not supported in a key name. If the key name include this character, the load key operation fails.

To add a Safenet HSM key by using the NetScaler command line

At the command prompt, type:

add ssl hsmkey <KeyName> -**hsmType SAFENET** -**serialNum** <serial #> -**password**

where:

-keyName is the key created on the HSM by using third party tools.

-serialNum is the serial number of the partition on the HSM on which the keys are generated.

-password is the password of the partition on which the keys are present.

To add a Safenet HSM key by using the NetScaler GUI

Navigate to **Traffic Management** > **SSL** > **HSM** and add an HSM key. You must specify the HSM Type as **SAFENET**.

3) Add a certificate-key pair on the ADC. You must first use a third party tool to generate a certificate associated with the key. Then, copy the certificate to the /nsconfig/ssl/ directory on the ADC.

Note: The key must be an HSM key.

To add a certkey pair on the ADC by using the NetScaler command line

At the command prompt, type:

add ssl certkey <CertkeyName> -**cert** <cert name> -**hsmkey** <KeyName>

To add a certkey pair on the ADC by using the NetScaler GUI

1. Navigate to **Traffic Management** > **SSL**.
2. In **Getting Started**, select **Install Certificate (HSM)** and create a certificate-key pair using an HSM key.

4) Create a virtual server and bind the certificate-key pair to this virtual server.

For information about creating a virtual server, see http://docs.citrix.com/en-us/netscaler/11/traffic-management/ssl/config-ssloffloading/config-ssl-vserver.html.

For information about adding a certificate-key pair, see http://docs.citrix.com/en-us/netscaler/11/traffic-management/ssl/config-ssloffloading/add-ssl-certkey.html.

High Availability Setup

Jun 23, 2016

You can configure a high availability (HA) setup with a SafeNet HSM configuration in either of the following two ways:

- First, configure a SafeNet HSM on the two nodes, using the same HSM and partition. Then create an HA pair. Finally, add the NetScaler configuration, such as keys, certificate-key pairs, and virtual servers, on the primary node.
- If a SafeNet HSM is already configured on one node with the NetScaler configuration, add a similar configuration on the other node. Copy "/var/safenet/sfgw_ident_file" from the first node to the other and restart the safenet_gw binary. After the gateway is up and running, add the nodes in an HA setup.

Limitations

Jun 23, 2016

1) For any changes to the HSM-related configuration in an existing setup, such as adding or removing an HSM, or creating a high availability setup, you must copy “/etc/Chrystoki.conf” to “/var/safenet/config”.

2) After adding, removing, or restarting an HSM, you must restart the “/var/safenet/gateway/safenet_gw” binary. If you don’t restart the gateway binary, the HSM will not serve any traffic after it is added back or after it restarts.

3) To reboot or stop the current “/var/safenet/gateway/safenet_gw” binary, use

- kill –SIGTERM <PID>
- kill –SIGINT <PID>

Important! Do not use “kill –9 <PID>” or “kill -6 <PID>”

4) Before removing an existing HSM from the ADC, remove, from the ADC, all the keys and certificate-key pairs that are associated with that HSM. You cannot delete these files from the ADC after you remove the HSM.

5) On a standalone NetScaler appliance, SafeNet HSMs in HA are not supported.

6) EXPORT and DH (ECDHE,DHE,EDH) ciphers are not supported.

7) Update certificate-key pair operation is not supported.

8) When you generate an HSM key on a third-party tool, the private and public key names must be the same. When you add the HSM key on the appliance, provide this name as the key name.

9) The # character is not supported in a key name.

10) Cluster and admin partitions are not supported.

Appendix

Feb 13, 2017

Sample commands with their outputs are given below.

run the script COPY

```
root@ns# pwd

/var/safenet/config

root@ns# sh safenet_config
```

Create a certificate COPY

```
root@ns# cd /var/safenet/safenet/lunaclient/bin

root@ns# ./vtl createcert -n 10.102.59.175

Private Key created and written to: /var/safenet/safenet/lunaclient/cert/client/10.102.59.175Key.pem

Certificate created and written to: /var/safenet/safenet/lunaclient/cert/client/10.102.59.175.pem
```

Copy the certificate to the HSM COPY

```
root@ns# scp /var/safenet/safenet/lunaclient/cert/client/10.102.59.175.pem admin@10.217.2.7:

admin@10.217.2.7's password:

10.102.59.175.pem          100%  818     0.8KB/s   00:00
```

Copy the certificate and key from the HSM to the NetScaler appliance COPY

```
root@ns# scp admin@10.217.2.7:server.pem /var/safenet/safenet/lunaclient/server.2.7.pem

admin@10.217.2.7's password:

server.pem          100% 1164     1.1KB/s   00:01
```

Use SSH to connect to the SafeNet HSM COPY

```
ssh admin@10.217.2.7

Connecting to 10.217.2.7:22...

Connection established.

To escape to local shell, press 'Ctrl+Alt+]'.
```

```
To escape to local shell, press 'Ctrl+Alt+[' ]

Save the configuration COPY

```
root@ns# cp /etc/Chrystoki.conf /var/safenet/config/
```

Configure automatic start of the gateway daemon at boot time COPY

```
touch /var/safenet/safenet_is_enrolled
```

FAQ

Jul 28, 2016

How do I check that the SafeNet process is running?

At the NetScaler shell prompt, type:

ps –aux | grep safenet_gw

How do I verify the network trust links (NTLs) connectivity between the ADC and HSM?

After configuring SafeNet, change directory to "/var/safenet/safenet/lunaclient/bin" and type:

./vtl verify

Troubleshooting

Jul 22, 2013

If the SSL feature does not work as expected after you have configured it, you can use some common tools to access NetScaler resources and diagnose the problem.

Resources for Troubleshooting

Updated: 2013-07-22

For best results, use the following resources to troubleshoot an SSL issue on a NetScaler appliance:

- The relevant ns.log file
- The latest ns.conf file
- The messages file
- The relevant newnslog file
- Trace files
- A copy of the certificate files, if possible
- A copy of the key file, if possible
- The error message, if any

In addition to the above resources, you can use the Wireshark application customized for the NetScaler trace files to expedite troubleshooting.

Troubleshooting SSL Issues

Updated: 2013-07-22

To troubleshoot an SSL issue, proceed as follows:

- Verify that the NetScaler appliance is licensed for SSL Offloading and load balancing.
- Verify that SSL Offloading and load balancing features are enabled on the appliance.
- Verify that the status of the SSL virtual server is not displayed as DOWN.
- Verify that the status of the service bound to the virtual server is not displayed as DOWN.
- Verify that a valid certificate is bound to the virtual server.
- Verify that the service is using an appropriate port, preferably port 443.

SSL FAQs

Jan 21, 2018

For the list of FAQs, see SSL FAQs.

404

Security

May 03, 2013

The following topics cover configuration and installation information for NetScaler security features. Most of these features are policy based.

Authentication, Authorization, Auditing (AAA)	Keeps unauthorized users out of the network, denies users access to tasks for which they are not authorized, and tracks the resources used during user sessions.
Application Firewall	Prevents security breaches, data loss, and possible unauthorized modifications to web sites that access sensitive business or customer information.
Content Filtering	Blocks inappropriate HTML requests, preventing the requests from reaching the Web servers.
HTTP Denial-of-Service Protection	Prevents hackers from attacking your Web site with large numbers of HTTP requests.
Priority Queuing	Detects high-priority connections and allows those connections to proceed ahead of other connections, guaranteeing unimpeded access to those users.
SureConnect	Services all incoming connections with either the requested content or a custom Web page that displays information about a delay in the request being serviced.
Surge Protection	Detects any rapid rise in connection attempts and adjusts the rate at which connections are allowed to proceed to the server, preventing server overload.

Content Filtering

Jul 20, 2017

Content filtering can do some of the same tasks as the Citrix NetScaler Application Firewall, and is a less CPU-intensive tool. It is limited, however, to examining the header portion of the HTTP request or response and to performing a few simple actions on connections that match. If you have a complex Web site that makes extensive use of scripts and accesses back-end databases, the Application Firewall may be the better tool for protecting that Web site. For more information about the Citrix NetScaler Application Firewall, see Application Firewall.

Content filtering is based on regular expressions that you can apply to either HTTP requests or HTTP responses. To block requests from a particular site, for example, you could use an expression that compares each request's URL to the URL specified in the expression. The expression is part of a policy, which also specifies an action to be performed on requests or responses that match the expression. For example, an action might drop a request or reset the connection.

Following are some examples of things you can do with content filtering policies:

- Prevent users from accessing certain parts of your Web sites unless they are connecting from authorized locations.
- Prevent inappropriate HTTP headers from being sent to your Web server, possibly breaching security.
- Redirect specified requests to a different server or service.

To configure content filtering, once you have made sure that the feature is enabled, you configure filtering actions for your servers to perform on selected connections (unless the predefined actions are adequate for your purposes). Then you can configure policies to apply the actions to selected connections. Your policies can use predefined expressions, or you can create your own. To activate the policies you configured, you bind them either globally or to specific virtual servers.

To configure content filtering, do the following:

1. Enabling Content Filtering
2. Configuring a Content Filtering Action
3. Configuring a Content Filtering Policy
4. Binding a Content Filtering Policy

Enabling Content Filtering

Oct 31, 2013

By default, content filtering is enabled on NetScaler appliances running the NetScaler operating system 8.0 or above. If you are upgrading an existing appliance from an operating system version earlier than 8.0, you must update the licenses before you can use content filtering, and you may need to enable the content filtering feature itself manually.

To enable content filtering by using the command line interface

At the command prompt, type the following commands to enable content filtering and verify the configuration:

- enable ns feature ContentFiltering
- show ns feature

Example

```
> enable ns feature ContentFiltering
 Done
> show ns feature

      Feature                 Acronym          Status
      -------                 -------          ------
1)    Web Logging             WL               ON
2)    Surge Protection        SP               OFF
.
.
.
.
11)   Http DoS Protection     HDOSP            OFF
12)   Content Filtering       CF               ON
.
.
23)   HTML Injection          HTMLInjection    ON
24)   NetScaler Push          push             OFF
Done
```

To enable content by filtering by using the configuration utility

1. In the navigation pane, expand System, and then select Settings.
2. In the details pane, click Configure basic features.
3. In the Configure Basic Features pane, select the Content Filter check box, and then click OK.

Configuring a Content Filtering Action

Sep 03, 2013

After you enable the content filtering feature, you create one or more actions to tell your NetScaler appliance how to handle the connections it receives.

Content filtering supports the following actions for HTTP requests:

Add

Adds the specified HTTP header before sending the request to the Web server.

Reset

Terminates the connection, sending the appropriate termination notice to the user's browser.

Forward

Redirects the request to the designated service.

Drop

Silently deletes the request, without sending a response to the user's browser.

Corrupt

Modifies the designated HTTP header in a manner that prevents it from performing the function it was intended to perform, then sends the request to the server.

Content filtering supports the following actions for HTTP responses:

Add

Adds the specified HTTP header before sending the response to the user's browser.

ErrorCode

Returns the designated HTTP error code to the user's browser.

Corrupt

Modifies the designated HTTP header in a manner that prevents it from performing the function it was intended to perform, then sends the response to the user's browser.

To configure a content filtering action by using the command line interface

At the command prompt, type the following commands to configure a Content Filtering action and verify the configuration:

- add filter action <name> <qualifier> [<serviceName>] [<value>] [<respCode>] [<page>]
- show filter action <name>

Example

```
> add filter action act_drop Drop
 Done
> show filter action act_drop
1)     Name: act_drop   Filter Type: drop
 Done
```

To configure a content filtering action by using the configuration utility

1. Navigate to Security > Protection Features > Filter.
2. In the details pane, do one of the following:
   - To create a new action, click Add.

- To modify an existing action, select the action, and then click Open.

3. In the Add Filter Action or Configure Filter Action dialog box, specify values for the parameters:
   - Action Name*—name
   - Qualifier*—qualifier (Determines which of the following parameters you can configure)
   - Service Name—servicename
   - HeaderName:Value—value
   - Response Code—respcode
   - Response Page—page
4. Fill in any other required information. For example, if you are configuring an action to send an HTTP error code, you must choose the appropriate error code from a drop-down list. If necessary, you can then modify the text of the error message, which is displayed beneath the drop-down list.
5. Click Create or OK, and then click Close. The Actions list displays the action you configured, and a message in the status bar indicates that your action has been created.

Configuring a Content Filtering Policy

Sep 03, 2013

To implement content filtering, you must configure at least one policy to tell your NetScaler appliance how to distinguish the connections you want to filter. You must first have configured at least one filtering action, because when you configure a policy, you associate it with an action.

Content filtering policies examine a combination of one or more of the following elements to select requests or responses for filtering:

URL

The URL in the HTTP request.

URL query

Only the query portion of the URL, which is the portion after the query (?) symbol.

URL token

Only the tokens in the URL, if any, which are the parts that begin with an ampersand (&) and consist of the token name, followed by an equals sign (=), followed by the token value.

HTTP method

The HTTP method used in the request, which is usually GET or POST, but can be any of the eight defined HTTP methods.

HTTP version

The HTTP version in the request, which is usually HTTP 1.1.

Standard HTTP header

Any of the standard HTTP headers defined in the HTTP 1.1 specification.

Standard HTTP header value

The value portion of the HTTP header, which is the portion after the colon and space (:).

Custom HTTP header

A non-standard HTTP header issued by your Web site or that appears in a user request.

Custom header value

The value portion of the custom HTTP header, which (as with the standard HTTP header) is the portion after the colon and space (:).

Client Source IP

The IP from which the client request was sent.

Content filtering policies use the simpler of two NetScaler expressions languages, called classic expressions. For a complete description of classic expressions, how they work, and how to configure them manually, see "Policies and Expressions."

Note: Users who are not experienced in configuring policies at the NetScaler command line will usually find using the configuration utility considerably easier.

To configure a content filtering policy by using the command line interface

At the command prompt, type the following commands to configure a content filtering policy and verify the configuration:

- add filter policy <name> -rule <expression> (-reqAction <action> | -resAction <string>
- show filter policy <name>

Example

```
> add filter policy cf-pol -rule "REQ.HTTP.URL CONTAINS http://abc.com" -reqaction DROP
 Done
> show filter policy cf-pol
1)     Name: cf-pol    Rule: REQ.HTTP.URL CONTAINS http://abc.com
       Request action: DROP
       Response action:
       Hits: 0
 Done
```

To configure a content filtering policy by using the configuration utility

1. Navigate to Security > Protection Features > Filter.
2. Navigate to Protection Features > Filter.
3. In the details pane, to create a new policy, click Add.
4. If you are creating a new policy, in the Create Filter Policy dialog box, in the Filter Name text box, type a name for your new policy.
5. Select either Request Action or Response Action to activate the drop-down list to the right of that item.
6. Click the down arrow to the right of the drop-down list and select the action to be performed on the request or response. The default choices are RESET and DROP. Any other actions you have created will also appear in this list.
   Note: You can also click New to create a new Content Filtering action, or Modify to modify an existing Content Filtering action. You can only modify actions you created; the default actions are read-only.
7. If you want to use a predefined expression (or named expression) to define your policy, choose one from the Named Expressions list.
   1. Click the down arrow to the right of the first Named Expressions drop-down list, and choose the category of named expressions that contains the named expression you want to use.
   2. Click the down arrow to the right of the second Named Expressions drop-down list, and choose the named expression you want. As you choose a named expression, the regular expression definition of that named expression appears in the Preview Expression pane beneath the Named Expression list boxes.
   3. Click Add Expression to add that named expression to the Expression list.

   Note: You should perform either this step or step 7, but not both.
8. If you want to create a new expression to define your policy, use the Expression Editor.
   1. Click the Add button. The Add Expression dialog box appears.
   2. In the Add Expression dialog box, choose the type of connection you want to filter. The Flow Type is set to REQ by default, which tells the NetScaler appliance to look at incoming connections, or requests. If you want to filter outgoing connections (responses), you click the right arrow beside the drop-down list and choose RES.
   3. If the Protocol is not already set to HTTP, click the down arrow to the right of the Protocol drop-down list and choose HTTP.
      Note: In the NetScaler classic expressions language, “HTTP” includes HTTPS requests, as well.
   4. Click the down arrow to the right of the Qualifier drop-down list, and then choose a qualifier for your expression. Your choices are:

      METHOD

      The HTTP method used in the request.

      URL

The contents of the URL header.

URLTOKENS

The URL tokens in the HTTP header.

VERSION

The HTTP version of the connection.

HEADER

The header portion of the HTTP request.

URLLEN

The length of the contents of the URL header.

URLQUERY

The query portion of the contents of the URL header.

URLQUERYLEN

The length of the query portion of the URL header.

The contents of the remaining list boxes change to the choices appropriate to the Qualifier you pick. For example, if you choose HEADER, a text field labeled Header Name* appears below the Flow Type list box.

5. Click the down arrow to the right of the Operator drop-down list, and choose an operator for your expression. Your choices will vary depending on the Protocol you chose in the preceding step. The following list includes all of the operators:

==

Matches the following text string exactly.

!=

Does not exactly match the following text string.

>

Is greater than the following integer.

CONTAINS

Contains the following text string.

CONTENTS

The contents of the designated header, URL, or URL query.

EXISTS

The specified header or query exists.

NOTCONTAINS

Does not contain the following text string.

NOTEXISTS

The specified header or query does not exist.

6. If the Value text box is visible, type the appropriate string or number. If you are testing a string in any way, type the string into the Value text box. If you are testing an integer in any way, type the integer into the Value text box.
7. If you chose HEADER as the Protocol, type the header you want in the Header Name* text box.
8. Click OK to add your expression to the Expressions list.
9. Repeat steps B through H to create any additional expressions you want for your profile.

10. Click Close to close the Expressions Editor.

9. If you created a new expression, in the Expression frame select an option from the Match Any Expression drop-down list. Your choices are:
   - Match Any Expression. If a request matches any expression in the Expressions list, the request matches this policy.
   - Match All Expressions If a request matches all expressions in the Expressions list, the request matches this policy. If it does not matchall of them, it does not match this policy.
   - Tabular Expression Switches the Expressions list to a tabular format with three columns. In the first column you can place a BEGIN [(] operator. The second column contains the expressions you have selected or created. In the third column, you can place any of the other operators in the following list, to create complex policy groups in which each group can be configured for match any expression or match all expressions.
   - The AND [&&] operator tells the appliance to require that are quest match both the current expression and the following expression.
   - The OR [||] operator tells the appliance to require that arequest match either the current expression or the following expression, or both. Only if the request does not match either expression does it not match the policy.
   - The END [)] operator tells the appliance that this is the last expression in this expression group or policy.
     Note: The Tabular format allows you to create a complex policy that contains both “Match Any Expression” and “Match All Expressions” on a per-expression basis. You are not limited to just one or the other.
   - Advanced Free-Form Switches off the Expressions Editor entirely and modifies the Expressions list into a text area. In the text area, you can type the PCRE-format regular expression of your choice to define this policy. This is both the most powerful and the most difficult method of creating a policy, and is recommended only for those thoroughly familiar with the NetScaler appliance and PCRE-formatregular expressions.
     Caution: If you switch to Advanced Free Form expression editing mode, you cannot switch back to any of the other modes. Do not choose this expression editing mode unless you are sure that is what you want.
10. Repeat steps 6 through 8 to add any additional expressions you want to the Expressions list. You can mix named expressions and expressions created in the Expressions Editor. To the NetScaler appliance, they are all the same.
11. Click Create to create your new policy. Your new policy appears in the Policies pane list.
12. Click Close. To create additional Content Filtering policies, repeat the previous procedure. To remove a Content Filtering policy, select the policy in the Policies tab and click Remove.

Binding a Content Filtering Policy

Oct 31, 2013

You must bind each content filtering policy to put it into effect. You can bind policies globally or to a particular virtual server. Globally bound policies are evaluated each time traffic directed to any virtual server matches the policy. Policies bound to a specific vserver are evaluated only when that vserver receives traffic that matches the policy.

To bind a policy to a virtual server by using the command line interface

At the command prompt, type the following commands to bind a policy to a virtual server and verify the configuration:

- bind lb vserver <name>@ -policyName <string> -priority <positive_integer>
- show lb vserver <name>

Example

```
> bind lb vserver vs-loadbal -policyName policyTwo -priority 100
 Done
> show lb vserver vs-loadbal
1)     vs-loadbal (10.102.29.20:80) - HTTP     Type: ADDRESS
       State: OUT OF SERVICE
       Last state change was at Wed Aug 19 09:05:47 2009 (+211 ms)
       Time since last state change: 2 days, 00:58:03.260
       Effective State: DOWN
       Client Idle Timeout: 180 sec
       Down state flush: ENABLED
       Disable Primary Vserver On Down : DISABLED
       Port Rewrite : DISABLED
       No. of Bound Services :  0 (Total)       0 (Active)
       Configured Method: LEASTCONNECTION
       Mode: IP
       Persistence: NONE
       Vserver IP and Port insertion: OFF
       Push: DISABLED  Push VServer:
       Push Multi Clients: NO
       Push Label Rule: none

 Done
```

To globally bind a policy by using the command line interface

At the command prompt, type the following commands to globally bind a policy and verify the configuration:

- bind filter global (<policyName> [-priority <positive_integer>]) [-state (ENABLED | DISABLED)]
- show filter global

Example

```
bind filter global cf-pol -priority 1
Done show filter global
```

1) Policy Name: cf-pol Priority: 1
Done

To bind a policy to a virtual server by using the configuration utility

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane, select the virtual server to which you want to bind the content filtering policy from the list, and click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, select the Policies tab, and then select the check box in the Active column of the filter policy that you want to bind to the virtual server.
4. Click OK. The policies you have bound display a check mark and the word Yes in the Policies Bound column of the Policies tab.

To globally bind a policy by using the configuration utility

1. Navigate to Security > Protection Features > Filter.
2. In the details pane, in the Policies tab, select the policy that you want to bind, and then click Global Bindings.
3. In the Bind/Unbind Filter Policies dialog box, in the Policy Name drop-down list, select a policy, and then click Add. The policy is added to the Configured list.
   Note: To select multiple policies from the list, press and hold the Ctrl key, then click each policy you want.
4. Click OK, and then click Close. The policies you have bound display a check mark and the word Yes in the Globally Bound column of the Policies tab.

Configuring Content Filtering for a Commonly Used Deployment Scenario

Oct 31, 2013

This example provides instructions for using the configuration utility to implement a content filtering policy in which, if a requested URL contains root.exe or cmd.exe, the content filtering policy filter-CF-nimda is evaluated and the connection is reset.

To configure this content filtering policy, you must do the following:

- Enable content filtering
- Configure content filtering policy
- Bind content filtering policy globally or to a virtual server
- Verify the configuration

Note: Since this example uses a default content filtering action, you do not need to create a separate content filtering action.

To enable content filtering

1. In the navigation pane, expand System, and click Settings.
2. In the details pane, under Modes & Features, click Change Basic Features.
3. In the Configure Basic Features dialog box, select the Content Filtering check box, and then click OK.
4. In the Enable/Disable feature(s) dialog box, click Yes. A message appears in the status bar, stating that the selected feature is enabled.

To configure the content filtering policy filter-CF-nimda

1. Navigate to Security > Protection Features > Filter.
2. In the details pane, click Add. The Create Filter Policy dialog box appears.
3. In the Create Filter Policy dialog box, in the Filter Name text box, type the name filter-CF-nimda.
4. Select the Request Action option, and in the drop-down list, select RESET.
5. In the Expression frame, select Match Any Expression from the drop-down list, and then click Add.
6. In the Add Expression dialog box, Expression Type drop-down list, select General.
7. In the Flow Type drop-down list, select REQ.
8. In the Protocol drop-down list, select HTTP.
9. In the Qualifier drop-down list, select URL.
10. In the Operator drop-down list, select CONTAINS.
11. In the Value text box, type cmd.exe, and then click OK. The expression is added in the Expression text box.
12. To create another expression, repeat Steps 7 through 11, but in the Value text box, type root.exe. Then click OK, and finally click Close.
13. Click Create on the Create Filter Policy dialog box. The filter policy filter-CF-nimda appears in the Filter list.
14. Click Close.

To globally bind the content filtering policy

1. Navigate to Security > Protection Features > Filter. The Filter page appears in the right pane.
2. In the details pane, Policies tab, select the policy that you want to bind and click Global Bindings. The Bind/Unbind Filter Policies dialog box appears.

3. In the Bind/Unbind Filter Policies dialog box, in the Policy Name drop-down list, select the policy filter-CF-nimda, and click Add. The policy is added to the Configured list.
4. Click OK, and then click Close. The policy you have bound displays a check mark and Yes in the Globally Bound column of the Policies tab.

To bind the content filtering policy to a virtual server

1. Navigate to Traffic Management > Load Balancing > Virtual Servers.
2. In the details pane virtual servers list, select vserver-CF-1 to which you want to bind the content filtering policy and click Open.
3. In the Configure Virtual Server (Load Balancing) dialog box, select the Policies tab.
4. In the Active column, select the check box for the policy filter-CF-nimda, and then click OK. Your content filtering policy is now active, and should be filtering requests. If it is functioning correctly, the Hits counter is incremented every time there is a request for a URL containing either root.exe or cmd.exe. This allows you to confirm that your content filtering policy is working. The content filtering policy is bound to the virtual server.

To verify the content filtering configuration by using the command line interface

At the command prompt, type the following command to verify the content filtering configuration:
show filter policy filter-CF-nimda
Example

```
sh filter policy filter-CF-nimda
    Name: filter-CF-nimda   Rule: REQ.HTTP.URL CONTAINS cmd.exe || REQ.HTTP.URL CONTAINS root.exe
    Request action: RESET
    Response action:
    Hits: 0
Done
```

Note: The Hits counter displays an integer that denotes the number of times the filter-CF-nimda policy is evaluated. In the preceding steps, the Hits counter is set to zero because no requests for a URL containing either cmd.exe or root.exe have been made yet. If you want to see the counter increment in real time, you can simply request a URL that contains either of these strings.

To verify the content filtering configuration by using the configuration utility

1. Navigate to Security > Protection Features > Filter.
2. In the details pane, select the filter policy filter-CF-nimda. The bottom of the pane should display the following:
   Request Action:

   RESET
   Rule:

   REQ.HTTP.URL CONTAINS cmd.exe || REQ.HTTP.URL CONTAINS root.exe
   Hits:

   0

Troubleshooting

Jul 22, 2013

If the content filtering feature does not work as expected after you have configured it, you can use some common tools to access NetScaler resources and diagnose the problem.

Resources for Troubleshooting

Updated: 2013-07-22

You can use the following tools and resources to troubleshoot most Content Filtering issues on a NetScaler appliance:

- The Wireshark application customized for the NetScaler trace files
- Trace files recorded when accessing the resource
- The configuration files
- The ns.log file
- The iehttpheaders, or a Fiddler trace or a similar utility

Troubleshooting Content Filtering Issues

Updated: 2013-08-02

To troubleshoot a content filtering issue, proceed as follows:

- Verify that the feature is enabled.
- Verify that the content filtering policy is configured correctly. Pay special attention to the expression that evaluates the incoming requests.
  Note: Most content filtering issues are caused by incorrect configuration, and the error is most often in the policy configuration.
- Check the policy's Hits counter to verify that it is incrementing. If it is not, the policy is not getting evaluated.
- If the policy is getting evaluated and the required filtering is still not performed, you need to look into the policy expressions and action.
- If the policy's expression seems valid, test it by assigning a simple NSTRUE value to see if the evaluation of the expression is creating any issue.
- Reevaluate whether the filtering should be based on the request or the response.
- Verify that the action is configured correctly. For example, if a custom action is used to corrupt a header in the request, verify that the header name in the action is correct. If you are not sure about the header name, start a browser with iehttpheaders or a similar utility, and then verify the headers in the request. When this feature is used, you can use nstrace to find out if appropriate action is performed when the packets leave NetScaler appliance.
- An iehttpheaders or Fiddler trace can help you find header options and names, client-side request headers, and response headers recorded on the client.
- To check the modifications made to the request header, record an nstrace on the NetScaler appliance or a Wireshark trace on the server.
- If none of the above measures resolves the issue, verify that the connection has not become untrackable, which can happen in certain circumstances. If a connection becomes untrackable, the appliance does not perform any application-level processing of the requests. In that event, contact Citrix Technical Support.

HTTP Denial-of-Service Protection

Mar 16, 2012

Internet hackers can bring down a site by sending a surge of GET requests or other HTTP-level requests. HTTP Denial-of-Service (HTTP Dos) Protection provides an effective way to prevent such attacks from being relayed to your protected Web servers. The HTTP DoS feature also ensures that a NetScaler appliance located between the internet cloud and your Web servers is not brought down by an HTTP DoS attack.

Most attackers on the Internet use applications that discard responses to reduce computation costs, and minimize their size to avoid detection. The attackers focus on speed, devising ways to send attack packets, establish connections or send HTTP requests as rapidly as possible.

Real HTTP clients such as Internet Explorer, Firefox, or NetScape browsers can understand HTML Refresh meta tags, Java scripts, and cookies. In standard HTTP the clients have most of these features enabled. However, the dummy clients used in DoS attacks cannot parse the response from the server. If malicious clients attempt to parse and send requests intelligently, it becomes difficult for them to launch the attack aggressively.

When the NetScaler appliance detects an attack, it responds to a percentage of incoming requests with a Java or HTML script containing a simple refresh and cookie. (You configure that percentage by setting the Client Detect Rate parameter.) Real Web browsers and other Web-based client programs can parse this response and then resend a POST request with the cookie. DoS clients drop the NetScaler appliance's response instead of parsing it, and their requests are therefore dropped as well.

Even when a legitimate client responds correctly to the NetScaler appliance's refresh response, the cookie in the client's POST request may become invalid in the following conditions:

- If the original request was made before the NetScaler appliance detected the DoS attack, but the resent request was made after the appliance had come under attack.
- When the client's think time exceeds four minutes, after which the cookie becomes invalid.

Both of these scenarios are rare, but not impossible. In addition, the HTTP DoS protection feature has the following limitations:

- Under an attack, all POST requests are dropped, and an error page with a cookie is sent.
- Under an attack, all embedded objects without a cookie are dropped, and an error page with a cookie is sent.

The HTTP DoS protection feature may affect other NetScaler features. Using DoS protection for a particular content switching policy, however, creates additional overhead because the policy engine must find the policy to be matched. There is some overhead for SSL requests due to SSL decryption of the encrypted data. Because most attacks are not on a secure network, though, the attack is less aggressive.

If you have implemented priority queuing, while it is under attack a NetScaler appliance places requests without proper cookies in a low-priority queue. Although this creates overhead, it protects your Web servers from false clients. HTTP DoS protection typically has minimal effect on throughput, since the test JavaScript is sent for a small percentage of requests only. The latency of requests is increased, because the client must re-issue the request after it receives the JavaScript. These requests are also queued

To implement HTTP DoS protection, you enable the feature and define a policy for applying this feature. Then you configure your services with the settings required for HTTP DoS. You also bind a TCP monitor to each service and bind your

policy to each service to put it into effect.

Layer 3-4 SYN Denial-of-Service Protection

May 18, 2017

Any NetScaler appliance with system software version 8.1 or later automatically provides protection against SYN DoS attacks.

To mount such an attack, a hacker initiates a large number of TCP connections but does not respond to the SYN-ACK messages sent by the victimized server. The source IP addresses in the SYN messages received by the server are typically spoofed. Because new SYN messages arrive before the half-open connections initiated by previous SYN messages time out, the number of such connections increases until the server no longer has enough memory available to accept new connections. In extreme cases, the system memory stack can overflow.

A NetScaler appliance defends against SYN flood attacks by using SYN cookies instead of maintaining half-open connections on the system memory stack. The appliance sends a cookie to each client that requests a TCP connection, but it does not maintain the states of half-open connections. Instead, the appliance allocates system memory for a connection only upon receiving the final ACK packet, or, for HTTP traffic, upon receiving an HTTP request. This prevents SYN attacks and allows normal TCP communications with legitimate clients to continue uninterrupted.

SYN DoS protection on the NetScaler appliance ensures the following:

- The memory of the NetScaler is not wasted on false SYN packets. Instead, memory is used to serve legitimate clients.
- Normal TCP communications with legitimate clients continue uninterrupted, even when the Web site is under SYN flood attack.

In addition, because the NetScaler appliance allocates memory for HTTP connection state only after it receives an HTTP request, it protects Web sites from idle connection attacks.

SYN DoS protection on your NetScaler appliance requires no external configuration. It is enabled by default.

Disabling SYN Cookies

SYN cookies are enabled by default on a NetScaler appliance to prevent SYN attacks. If your deployment requires you to disable SYN cookies, for example, for server-initiated data connections or in cases where a connection is not established because the first packet is dropped or reordered, use one of the following methods to disable SYN cookies.

To disable SYN cookies by using the NetScaler command line

At the command prompt, type:

set nstcpprofile nstcp_default_profile -synCookie DISABLED

Arguments

synCookie

Enable or disable the SYNCOOKIE mechanism for TCP handshake with clients. Disabling SYNCOOKIE prevents SYN attack protection on the NetScaler appliance.

Possible values: ENABLED, DISABLED

Default: ENABLED

To disable SYN cookies by using the NetScaler GUI

1. Navigate to **System** > **Profiles** > **TCP Profiles**.
2. Select a profile and click **Edit**.
3. Clear the **TCP SYN Cookie** check box.
4. Click **OK**.

Enabling HTTP DoS Protection

Sep 03, 2013

To configure HTTP DoS protection, you must first enable the feature.

To enable HTTP DoS protection by using the command line interface

At the command prompt, type the following commands to enable HTTP DoS protection and verify the configuration:

- enable ns feature HttpDoSProtection
- show ns feature

Example

```
> enable ns feature HttpDoSProtection
 Done
> show ns feature

      Feature                 Acronym          Status
      -------                 -------          ------
 1)   Web Logging             WL               ON
 2)   Surge Protection        SP               OFF
 .
 .
 .
 10)  Global Server Load Balancing  GSLB       ON
 11)  Http DoS Protection    HDOSP            ON
 12)  Content Filtering       CF               ON
 .
 .
 23)  HTML Injection          HTMLInjection    ON
 24)  NetScaler Push          push             OFF
 Done
>
```

To enable HTTP DoS protection by using the configuration utility

1. Navigate to System > Settings.
2. In the details pane, click Configure Advanced Features.
3. In the Configure Advanced Features dialog box, select the HTTP DoS Protection check box.
4. Click OK.

Defining an HTTP DoS Policy

Feb 13, 2017

After you enable HTTP DoS protection, you next create a policy.

Note: Before changing the default setting for Client Detect Rate, see "Tuning the Client Detection/JavaScript Challenge Response Rate."

At the command prompt, type one of the following commands to configure an HTTP DoS policy and verify the configuration:

- add dos policy <name> -qDepth <positive_integer> [-cltDetectRate <positive_integer>]
- set dos policy <name> -qDepth <positive_integer> [-cltDetectRate <positive_integer>]

Example

```
> add dos policy pol-HTTP-DoS  -qDepth 30
 Done
> set dos policy pol-HTTP-DoS  -qDepth 40
 Done
> show dos policy
1)     Policy: pol-HTTP-DoS    QDepth: 40
 Done
>
```

1. Navigate to Security > Protection Features > HTTP DoS.
2. In the details pane, do one of the following:
   - To create a new policy, click Add.
   - To modify an existing policy, select the policy, and then click Open.
3. In the Create HTTP DoS Policy or Configure HTTP DoS Policy dialog box, specify values for the parameters:
   - Name*—name (You cannot change the name of an existing policy.)
   - QDepth*—qdepth
   - Client Detect Rate—cltDetectRate (Before changing the default setting for cltDetectRate, see "Tuning the Client Detection/JavaScript Challenge Response Rate."
4. Click OK to create your new policy. The policy that you created appears in the details pane, and the status bar displays a message indicating that the DoS policy is successfully configured.

Configuring an HTTP DoS Service

Sep 03, 2013

After you configure an HTTP DoS policy, you must configure a service for your policy. The service accepts HTTP traffic that is protected by the HTTP DoS policy.

At the command prompt, type one of the following commands to configure an HTTP DoS service and verify the configuration:

- add service <name>@ (<IP>@ | <serverName>@) HTTP <port> [-maxClient <positive_integer>] [-maxReq <positive_integer>] -state ENABLED
- set service <name>@ (<IP>@ | <serverName>@) HTTP <port> [-maxClient <positive_integer>] [-maxReq <positive_integer>] -state ENABLED

Example

```
> add service ser-HTTP-Dos1 10.102.29.40 HTTP 87
 Done
> set service ser-HTTP-Dos1 -maxReq 20
 Done
> show service
1)     srv-http-10 (10.102.29.30:80) - HTTP
       State: DOWN
       Last state change was at Wed Jul  8 07:49:52 2009
       Time since last state change: 34 days, 00:48:18.700
       Server Name: 10.102.29.30
       Server ID : 0   Monitor Threshold : 0
       Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
       Use Source IP: NO
       Client Keepalive(CKA): NO
       Access Down Service: NO
       TCP Buffering(TCPB): NO
       HTTP Compression(CMP): NO
       Idle timeout: Client: 180 sec   Server: 360 sec
       Client IP: DISABLED
       Cacheable: NO
       SC: OFF
       SP: OFF
       Down state flush: ENABLED
        .
        .
        .

5)     ser-HTTP-Dos1 (10.102.29.40:87) - HTTP
       State: DOWN
       Last state change was at Tue Aug 11 08:23:40 2009
       Time since last state change: 0 days, 00:14:30.300
```

Server Name: 10.102.29.40
Server ID : 0 Monitor Threshold : 0
Max Conn: 0 Max Req: 20 Max Bandwidth: 0 kbits
Use Source IP: NO
Client Keepalive(CKA): NO
Access Down Service: NO
TCP Buffering(TCPB): NO
HTTP Compression(CMP): YES
Idle timeout: Client: 180 sec Server: 360 sec
Client IP: DISABLED
Cacheable: NO
SC: OFF
SP: OFF
Down state flush: ENABLED
Done
>

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, do one of the following:
   - To create a new service, click Add.
   - To modify an existing service, select the service, and then click Open.
3. In the Create Server or Configure Server dialog box, specify values for the following parameters, which correspond to the descriptions in "Parameters for configuring an HTTP DoS service" as follows (asterisk indicates a required parameter):
   - Service Name*—name (You cannot change the name of an existing service.)
   - Server*—IP or serverName (Specify one or the other, not both.)
   - Port*—port
4. If the Enable Service check box is not selected, select it.
5. Select the Advanced tab, and select the Override Global check box to enable those choices.
6. Specify values for the following parameters.
   - Max Clients*—maxClient
   - Max Requests*—maxReq
7. Click Create or OK, and then click Close. The service appears in the list of services.

Binding an HTTP DoS Monitor and Policy

Sep 03, 2013

To put HTTP DoS protection into effect after you have configured an HTTP DoS service, you must bind the monitor, and then bind the service to the HTTP DoS policy.

At the command prompt, type the following commands to bind the monitor to the service and verify the configuration:

- bind lb monitor <monitorName> <serviceName>
- show lb monitor

Example

```
> bind lb monitor tcp ser-HTTP-DoS
 Done
> show lb monitor
1)  Name.......:  ping-default  Type......:    PING  State....ENABLED
2)  Name.......:  tcp-default  Type......:    TCP  State....ENABLED
3)  Name.......:  ping  Type......:    PING  State....ENABLED
4)  Name.......:  tcp  Type......:    TCP  State....ENABLED
5)  Name.......:  http  Type......:    HTTP  State....ENABLED
.
.
.
17)  Name.......:  ldns-dns  Type......: LDNS-DNS  State....ENABLED
 Done
```

At the command prompt, type the following commands to bind the policy to the service and verify the configuration:

bind service <serviceName> -policyName <policyname>

Example

```
> bind service ser-HTTP-DoS -policyName pol-HTTP-DoS
 Done
> show service
1)   srv-http-10 (10.102.29.30:80) - HTTP
     State: DOWN
     Last state change was at Wed Jul  8 07:49:52 2009
     Time since last state change: 34 days, 01:24:58.510
     Server Name: 10.102.29.30
     Server ID : 0   Monitor Threshold : 0
     Max Conn: 0     Max Req: 0      Max Bandwidth: 0 kbits
     Use Source IP: NO
     Client Keepalive(CKA): NO
     Access Down Service: NO
     TCP Buffering(TCPB): NO
     HTTP Compression(CMP): NO
```

Idle timeout: Client: 180 sec Server: 360 sec
Client IP: DISABLED
Cacheable: NO
SC: OFF
SP: ON
Down state flush: ENABLED
.
.
.

4) ser-HTTP-Dos (10.102.29.18:88) - HTTP
State: DOWN
Last state change was at Tue Aug 11 08:19:45 2009
Time since last state change: 0 days, 00:55:05.40
Server Name: 10.102.29.18
Server ID : 0 Monitor Threshold : 0
Max Conn: 0 Max Req: 0 Max Bandwidth: 0 kbits
Use Source IP: NO
Client Keepalive(CKA): NO
Access Down Service: NO
TCP Buffering(TCPB): NO
HTTP Compression(CMP): YES
Idle timeout: Client: 180 sec Server: 360 sec
Client IP: DISABLED
Cacheable: NO
SC: OFF
SP: ON
Down state flush: ENABLED

5) ser-HTTP-Dos1 (10.102.29.40:87) - HTTP
State: DOWN
Last state change was at Tue Aug 11 08:23:40 2009
Time since last state change: 0 days, 00:51:10.110
Server Name: 10.102.29.40
Server ID : 0 Monitor Threshold : 0
Max Conn: 0 Max Req: 20 Max Bandwidth: 0 kbits
Use Source IP: NO
Client Keepalive(CKA): NO
Access Down Service: NO
TCP Buffering(TCPB): NO
HTTP Compression(CMP): YES
Idle timeout: Client: 180 sec Server: 360 sec
Client IP: DISABLED
Cacheable: NO
SC: OFF
SP: OFF
Down state flush: ENABLED

Done
>

1. Navigate to Traffic Management > Load Balancing > Services.
2. In the details pane, select the service that you want to bind, and then click Open.
3. In the Configure Service dialog box, select the Monitor tab, click the name of the monitor you want in the Monitors list, and then click Add. The selected monitor is added to the Configured frame.
4. Select the Policies tab, then select the HTTP DoS tab.
5. Select a policy from the Available Policies list, and then click Add. The policy appears in the Configured Policies list.
6. Click OK, and then click Close. A message appears in the status bar, stating that the service has been configured.

Tuning the Client Detection/JavaScript Challenge Response Rate

Feb 13, 2017

After you have enabled and configured HTTP DoS protection, if more than the maximum specified number of clients are waiting in the NetScaler surge queue for the HTTP DoS service, the HTTP DoS protection function is triggered. The default rate of challenged JavaScript responses sent to the client is one percent of the server response rate. The default response rate is inadequate in many real attack scenarios, however, and may need to be tuned.

For example, assume that the web server is capable of a maximum of 500 responses/sec, but is receiving 10,000 requests/sec. If 1% of the server responses are sent as JavaScript challenges, responses are reduced to almost none: 5 client (500 *0.01) JavaScript responses, for 10000 waiting client requests. Only about 0.05% of the real clients receive JavaScript challenge responses. However, if the client detection/JavaScript challenge response rate is very high (for example, 10%, generating 1000 challenge JavaScript responses per second), it may saturate the upstream links or harm the upstream network devices. Exercise care when modifying the default **Client Detect Rate** value.

If the configured triggering surge queue depth is, for example, 200, and the surge queue size is toggling between 199 and 200, the NetScaler toggles between the “attack” and “no-attack” modes, which is not desirable. The HTTP DoS feature includes a window mechanism with a default size of 20. After the surge queue size reaches the specified queue depth value, triggering “attack” mode, the surge queue size must fall to 20 less than the specified queue depth for the NetScaler appliance to enter “no-attack” mode. In the example, the surge queue size must fall below 180 before the appliance enters “no-attack” mode. During configuration, you must specify a value more than 20 for the **QDepth** parameter when adding a DoS policy or setting a DoS policy.

The triggering surge queue depth should be configured on the basis of previous observations of traffic characteristics. For more information about setting up a correct configuration, see "Guidelines for HTTP DoS Protection Deployment."

Guidelines for HTTP DoS Protection Deployment

Mar 16, 2012

Citrix recommends you to deploy the HTTP DoS protection feature in a tested and planned manner and closely monitor its performance after the initial deployment. Use the following information to fine-tune the deployment of HTTP DoS Protection.

- The maximum number of concurrent connections supported by your servers.
- The average and normal values of the concurrent connections supported by your servers.
- The maximum output rate (responses/sec) that your server can generate.
- The average traffic that your server handles.
- The typical bandwidth of your network.
- The maximum bandwidth available upstream.
- The limits affecting bandwidth (such as external links, a particular router, or other critical devices on the path that may suffer from a traffic surge).
- Whether allowing a greater number of clients to connect is more important than protecting upstream network devices.

To determine the characteristics of a HTTP DoS attack, you should consider the following issues.

- What is the rate of incoming fake requests that you have experienced in the past?
- What types of requests have you received (complete posts, incomplete gets)?
- Did previous attacks saturate your downstream links? If not, what was the bandwidth?
- What types of source IP addresses and source ports did the HTTP requests have (e.g., IP addresses from one subnet, constant IP, ports increasing by one).
- What types of attacks do you expect in future? What type have you seen in the past?
- Any or all information that can help you tune DoS attack protection.

Priority Queuing

Sep 03, 2013

The priority queuing feature lets you filter incoming HTTP traffic on the basis of categories that you create and define, and prioritize those HTTP requests accordingly. Priority queuing directs high-priority requests to the server ahead of low-priority requests, so that users who need resources for important business uses receive expedited access to your protected Web servers.

Note: The priority queuing feature is not supported in NetScaler 9.2 nCore.
To implement priority queuing, you create priority queuing policies that specify a priority, weight, threshold, and implicit action. When an incoming request matches a priority queuing policy, the request is processed as the associated action indicates. For example, you can create a priority queuing policy that places all matching requests above a certain threshold in a surge queue, while giving priority treatment to other requests.

You can bind up to three priority queuing policies to a single load balancing virtual server. The priority levels are:

Level 1

A Level 1 policy processes priority requests.

Level 2

A Level 2 policy processes requests that should receive responses as soon as Level 1 requests have been cleared from the queue.

Level 3

A Level 3 policy processes non-priority requests that receive responses only after requests in the first two queues have been cleared.

You can use weighted queuing to adjust the relative priority of each of these queues. Weights can range from 0 to 101. A weight of 101 tells the NetScaler appliance to clear all requests in that queue before forwarding any requests in the lower-priority queues to the Web server. A weight of 0 tells the appliance to send requests in that queue to the Web server only when there are no requests waiting in any of the other queues.

You must assign a unique name to each priority queuing policy. Policy names can be up to 127 characters. Multiple policies bound to the same load balancing virtual server cannot have the same priority level. No two virtual servers that have one or more common underlying physical services can have priority queuing configured or enabled on both virtual servers simultaneously.

To configure priority queuing the NetScaler, you perform the following steps:

- Enable the load balancing feature
- Define a server and service
- Define a load balancing virtual server
- Bind the service to the load balancing virtual server
- Enable the priority queuing feature
- Create the priority queuing policies
- Bind the priority queuing policies to the load balancing virtual server
- Enable priority queuing on load balancing virtual server

For information about enabling load balancing, creating servers, creating virtual servers and services, and binding these servers and services, see the *Citrix NetScaler Traffic Management Guide* at http://support.citrix.com/article/CTX132359. For

complete information about policies and expressions, see the *Citrix NetScaler Policy Configuration and Reference Guide* at http://support.citrix.com/article/CTX132362.

Enabling Priority Queuing

Sep 03, 2013

To use the priority queuing feature the NetScaler appliance, you must first enable it.

At the command prompt, type the following commands to enable priority queuing and verify the configuration:

- enable ns feature PriorityQueuing
- show ns feature

Example

```
> enable ns feature PriorityQueuing
 Done
> show ns feature

      Feature                Acronym          Status
      -------                -------          ------
 1)   Web Logging             WL               ON
 2)   Surge Protection        SP               OFF
 3)   Load Balancing          LB               ON
 .
 .
 .
 8)   Priority Queuing        PQ               ON
 .
 23)  HTML Injection          HTMLInjection    ON
 24)  NetScaler Push          push             OFF
Done
```

1. Navigate to System > Settings.
2. In the details pane, click Configure advanced features.
3. In the Configure Advanced Features dialog box, select the Priority Queuing check box.
4. Click OK.

Configuring a Priority Queuing Policy

Feb 13, 2017

To configure a priority queuing policy, you can use either the configuration utility or the command line.

Note: For more information about using the command line, see "Command Reference."

At the command prompt, type the following command to configure a priority queuing policy and verify the configuration:

add pq policy <policyName> -rule <expression> -priority <positive_integer> [-weight <positive_integer>] [-qDepth <positive_integer> | -polqDepth <positive_integer>]

Example

```
> add pq policy pol_cgibin -rule "URL == '/cgi-bin/'" -priority 1
 Done
> show pq policy pol_cgibin
1)     Policy: pol_cgibin      Rule: URL == '/cgi-bin/'       Priority: 1     Weight: 10
       Hits: 0
 Done
```

1. Navigate to Security > Protection Features > Priority Queuing.
2. In the details pane, do one of the following:
   - To create a new policy, click Add.
   - To modify an existing policy, select the policy, and then click Open.
3. If you are creating a new policy, in the Create PQ Policy dialog box, in the Name text box, type a name for your new policy.
   The name can consist of from one to 127 letters, numbers and the hyphen and underscore symbol.

   If you are modifying an existing policy, skip this step. You cannot change the name of an existing policy.

4. In the Rule text box, either enter the policy expression directly, or click New to create a policy expression. If you click New, perform the following steps:
   1. In the Create Expression dialog box, click Add.
   2. In the Add Expression dialog box, leave Expression Type set to General, and in the Flow Type drop-down list, select a Flow Type. Your choices are REQ (for requests) and RES (for responses).
   3. In the Protocol drop-down list, select a protocol. If you selected REQ in the previous step, your choices are HTTP (Web-based connections), SSL (secure Web connections), TCP and IP. If you selected RES in the previous step, your choices are HTTP, TCP and IP.
   4. In the Qualifier drop-down list, select a qualifier.
      Your choices depend upon your selections in the previous step. Common choices are HTTP VERSION (the version of the HTTP connection), HTTP HEADER (the specified HTTP header), TCP SOURCEPORT/ DESTPORT (the source or destination port of a TCP connection), and IP SOURCEIP/DESTIP (the source or destination IP of the connection).

      If you choose HTTP HEADER, the Header text box appears beneath the original row of text boxes. You fill in the name of the HTTP header you want.

      For a complete description of the available choices, see "Policies and Expressions."

5. In the Operator drop-down list, select an operator.
   For a complete description of the available choices, see "Policies and Expressions."

6. In the Value text box, type the value you want to test for.
   This may be a text string or a number, depending upon the context. For a complete description of values appropriate to the specific context, see "Policies and Expressions."

7. Click OK. The expression is added in the Expression text box.
8. Click Create. The expression appears in the Rule text box.

5. In the Priority and Weight text boxes, type numeric values, for example, 1 and 30. For more information about Priority and Weight, see "Setting Up Weighted Queuing."
6. Enter a numeric value for either Queue Depth or Policy Queue Depth, for example 234, and click Create.
   - Queue Depth Defines the total number of waiting clients or requests on the virtual server to which the policy is bound.
   - Policy Queue Depth Defines the total number of waiting clients or requests belonging to the policy.

   The policy is created and appears in the Priority Queuing page.
   Note: To create additional priority queuing policies, repeat the procedure in the preceding section, and click Close after you finish.

Binding a Priority Queuing Policy

Sep 03, 2013

After you create a priority queuing policy, you must bind it to the appropriate virtual server to put it into effect.

At the command prompt, type the following commands to bind a policy and verify the configuration:

- bind lb vserver <name> -policyName <policyname>
- show lb vserver <name>

Example

```
> bind lb vserver lbvip -policyname pol_cgibin
 Done
> show lb vserver lbvip
      lbvip (8.7.6.6:80) - HTTP       Type: ADDRESS
      State: DOWN
      Last state change was at Wed Jul 15 05:54:24 2009 (+782 ms)
      Time since last state change: 26 days, 05:44:37.370
      Effective State: DOWN
      Client Idle Timeout: 180 sec
      Down state flush: ENABLED
      Disable Primary Vserver On Down : DISABLED
      Port Rewrite : DISABLED
      No. of Bound Services :  0 (Total)       0 (Active)
      Configured Method: LEASTCONNECTION
      Mode: IP
      Persistence: NONE
      Vserver IP and Port insertion: OFF
      Push: DISABLED  Push VServer:
      Push Multi Clients: NO
      Push Label Rule: none

1)     Policy : ns_cmp_msapp Priority:0

1)     Priority Queuing Policy : pol_cgibin
 Done
>
```

1. In the navigation pane, locate and select the virtual server to which you want to bind the priority queuing policy.
   - To select a load balancing virtual server, expand Traffic Management > Load Balancing > Virtual Servers, then select the load balancing virtual server that you want..
   - To select a content switching virtual server, expand Traffic Management > Content Switching > Virtual Servers, then select the content switching virtual server that you want..
2. In the Configure Virtual Server dialog box, select the Policies tab.

3. Click the double right-arrow (») symbol to display the complete list of policy types, and then select Priority Queuing from the drop-down list.
4. Click Insert Policy.
5. In the Policy Name row, select the policy that you want to bind from the drop-down list.
6. ClickOK to save your changes.

Setting Up Weighted Queuing

Feb 13, 2017

When priority queuing is implemented, lower-priority requests are typically kept on hold while higher-priority requests are served. The lower-priority requests may therefore be delayed if there is a constant flow of higher-priority requests.

To prevent delays for low-priority requests across multiple priority levels, you can configure weighted queuing for serving requests. The default weights for the priorities are:

- Gold - Priority 1 - Weight 3
- Silver - Priority 2 - Weight 2
- Bronze - Priority 3 - Weight 1

You assign the minimum weight, zero (0), to requests that the NetScaler appliance should send to the server only if no requests are stored in any of the other queues. You assign the maximum weight, 101, to requests that the appliance should send to the server immediately, ahead of any requests stored in any of the other queues. Weights between these two set the relative priority of a particular queue in relation to the other queues. Queues with a higher weight are processed first; queues with a lower weight after the others have been processed. To assign the weights, see "Configuring a Priority Queuing Policy."

Note: The weight assigned to a higher-priority queue must be larger than the weight assigned to a lower-priority queue. For example, the weight assigned to The Gold (Priority 1) queue must be greater than the weight assigned to the Silver (Priority 2) queue.

SureConnect

Sep 03, 2013

You can use the SureConnect feature of the Citrix NetScaler appliance to service all incoming connections with either the requested content or a custom Web page that displays information about a delay in the request being serviced.

When servers are overloaded with the requests, the servers might either respond slowly or not at all. The SureConnect feature enables the NetScaler appliance to detect and compensate such conditions by ensuring that every client request gets serviced in some way, such as either a custom Web page or actual content is sent to the client.

SureConnect is activated when the response time or maximum server connections to a client request exceeds a limit that you have set. The SureConnect browser window displays one of the following:

- A progress bar with the amount of time remaining until the requested content will be available.
- Alternate Web content of your choice (alternate page).
- Both a progress bar and alternate page.
- Complete custom content of your choice.

You can configure whether the SureConnect progress bar alone is displayed or both the progress bar and the alternate page are displayed.

When the server becomes responsive again, the original request for content is served. If the user chooses, the alternate content window can remain in focus.

Subsequent requests from the same user within the same session are served immediately. This can be configured using the settings described later in this section.

SureConnect can be activated when a response is delayed, and when the number of user connections to a given URL exceeds a specified threshold.

SureConnect works with all standard browsers, including Microsoft Internet Explorer, Netscape Navigator, and Mozilla Firefox.

SureConnect is advantageous in the following situations:

- **Full server queue**

  The server can respond fast, but there are too many users. This results in the server's queue being full and unable to process additional client requests.

  SureConnect Solution: In this situation, the SureConnect window is displayed, showing the time left until the content will be available. The alternate page is displayed under the progress bar, if an alternate page has been configured.

- **Large response delay**

  The server response is slow. Typically, if a Web server does not respond to a client request quickly, the user will leave the site.

  SureConnect Solution: When the predicted delay reaches a configured time threshold, the SureConnect window displays the progress bar and the optional alternate page in the client browser.

- **Client time-out**

When the client requests content from a very slow Web site, a time-out message displays in the client browser, and the content is not delivered. The user may leave the site.

SureConnect Solution: The appliance stores the request until the server is no longer busy and delivers the requested content to the client.

- **Server experiencing a traffic surge**

  The server typically responds quickly, but the current load of open connections is greater than the server capacity to serve them. Therefore, the server response is delayed.

  SureConnect Solution: A SureConnect window is displayed in the client browser, showing the time left. The alternate page from the server is also displayed if it has been configured.

Installing SureConnect

Mar 21, 2012

SureConnect files must be installed on the alternate content server, which can be the same as the primary server.

On a Windows server, extract the sc_xx.exe file (where xx is the build number), or on a UNIX server, extract the sc_xx.tar file (where xx is the build number).

Note: You must install SureConnect in the default Web root directory.
If the alternate content server is the same as the primary server, place the SureConnect and alternate content files in any directory under the Web root directory. Specify this path when you add a policy to configure SureConnect. By default, SureConnect files are installed in the /Citrix NetScaler appliance directory under the default Web root directory.

If the alternate content server is different than the primary server, the SureConnect and alternate content files must be in a unique directory under the Web root directory. By default, this unique directory is the /Citrix NetScaler system directory. Specify this path when you add a policy to configure SureConnect.

The following files are extracted:

- Alternate content files (progressbar.htm, alternatepage.htm, and barandpage.htm)
- System-Logo.gif
- Customer-Logo.gif
- Sample.gif
- README.txt.

This section describes how to install SureConnect alternate content on a UNIX server. The following are the prerequisites:

- The UNIX server is running the Apache server.
- The shell with the # prompt is in use.
- Apache is installed in the default location.
- The sc_xx.tar file is downloaded from the organization's Web site into the /var/ftp/incoming directory.

To install SureConnect

1. At the command prompt, navigate to the htdocs directory:
   cd /usr/local/apache/htdocs
2. Type the following command:
   tar xvpf/var/ftp/incoming/sc_xx.tar

The output from the .tar file is displayed. A /Citrix NetScaler system directory is created under the specified path and the SureConnect files are installed.

Updated: 2013-09-03

This section describes how to install SureConnect alternate content on a Windows server. The following are the prerequisites:

- The server is running the Microsoft Internet Information Server.
- The DOS prompt is being used.

- The SureConnect zip (self-extracting) file is downloaded from the organization Web site using FTP into the C:\inetpub\wwwroot directory.

To install SureConnect on Windows

Do one of the following:

- At the command prompt, navigate to the wwwroot directory:
  cd c:\inetpub\wwwroot
- Type the name of the executable file:
  sc_xx.exe
- Double-click the sc_xx.exe icon from the Microsoft Windows Explorer Web browser, extract from the compressed file into the default path (for example, the c:\inetpub\wwwroot directory).

Output from the zip file is displayed. A /Citrix NetScaler system directory is created under the specified path, and the SureConnect files are installed.

Configuring SureConnect

Feb 13, 2017

The following topics describe how to configure SureConnect for scenarios involving alternate server failure.

- Configuring the Response for Alternate Server Failure
- Configuring the SureConnect Policies
- Customizing the Alternate Content File
- Configuring SureConnect for Citirx NetScaler Features

Updated: 2013-09-03

If the alternate server fails, and the primary server cannot immediately deliver the requested content to the client, SureConnect does not display alternate content from the failed alternate server in the client Web browser.

The Citrix NetScaler appliance automatically sends a response to the client browser. You can customize the server response to display information suited to your needs.

The default response is:

Your Request is being processed… Estimated Time: _____ Secs

Customizing the Default Response

The NetScaler appliance automatically sends the response to the client if the alternate server fails, or if the appliance is configured to send the default response.

To customize the default response of the appliance, create a vsr.htm file (a sample is provided in this section) as follows:

- The file can contain any valid HTML statements other than embedded objects.
- The file size cannot exceed 800 bytes.
- The file must reside on the NetScaler appliance. If you have a high availability (HA) setup, the file must reside on the primary and secondary nodes. Any changes made to the file on the primary node must also be applied to the file on the secondary node.
- Put vsr.htm file in the /etc directory.

Change any of the contents between the </HEAD> and </HTML> tags in the vsr.htm file. Following is the sample content from vsr.htm file. The sections that you can edit are in bold text.

```
HTTP/1.1 200 OK
Server: NS_WS3.0
Content-Type: text/html
Cache-control: no-cache
Pragma: no-cache
Set-Cookie: NSC_BPIP=@@SID@@; path=/
<HTML> <HEAD> <META HTTP-EQUIV="Refresh" CONTENT="0">
```

</HEAD> **Your request is being processed...**
**
Estimated Delay: @@DELAY@@ Sec ** </HTML>
Note: Include @@DELAY@@ to display the predicted delayed response time in seconds.

SureConnect with In-Memory response (NS action)

Updated: 2013-09-03

When defining the SureConnect policy by using the add sc policy command, you can configure the NetScaler Appliance to serve alternative content to the client.

To enable SureConnect and configure the in-memory response, perform the following tasks:

- Enable the SureConnect feature on the appliance by using the enable feature SC command
- Define the services by using the add service <servicename> <IP address> <servicetype> <port> command. This identifies the original server for which the SureConnect is configured and the types of services.
- Add a SureConnect policy by using the add sc policy command. You can configure a URL-based policy or a rule-based policy. The incoming requests are validated against the URL or rule you specify in the policy.

Note: You can configure the SureConnect feature on a load balancing virtual server. In that case, perform the following additional actions:

- Enable Load Balancing by using the enable feature LB command.
- Enable SureConnect feature on the virtual server by using the set lb vserver <vservername> -sc ON command.
- Bind services to the virtual server by using the bind lb vserver <name> <serviceName> command.
- Bind policies to the virtual server by using the bind lb vserver <name> -policyname <name> command.

The following example illustrates how to configure SureConnect for the load balancing feature so that SureConnect will display alternative content from the NetScaler appliance.

In this example, two physical servers, with IP addresses, 10.101.3.187 and 10.101.3.188 are load balanced by the NetScaler appliance. The appliance has one configured virtual server, vs-NSact, whose IP address is 10.101.3.201. The file that contains the alternative content is vsr.htm. It is copied from the file system into system memory. Services are loaded until the SureConnect policy triggers, and the appliance supplies the alternate content.

```
enable feature SC LB
add service psvc1 10.101.3.187 http 80
add service psvc2 10.101.3.188 http 80
add lb vserver vs-NSact HTTP 10.101.3.201 80
bind lb vserver vs-NSact psvc1
bind lb vserver vs-NSact psvc2
add sc policy policyNS -url /cgi-bin/*.cgi -delay 400000
-action NS
set sc parameter -vsr /nsconfig/ssl/vsr.htm
bind lb vserver vs-NSact -policyName policyNS
set lb vserver vs-NSact -sc ON
save config
```

Table 1. Parameter values used in this example

Service	

Name	psvc1, psvc2
Server	10.101.3.187, 10.101.3.188
Protocol	HTTP
Port	80
Load Balancing Virtual Server	
Name	vs-NSact
IP Address	10.101.3.201
Protocol	HTTP
Port	80
SureConnect Policy	
Name	policyNS
URL	/cgi-bin/*.cgi
Delay(microseconds)	400000
SC Parameter	
VSR File Name	vsr.htm

1. In the In the navigation pane, navigate to System > Settings. In the Modes and Features pane, perform the following actions:
   1. Click Configure Basic Features, select Load Balancing, and Click Go.
   2. Click Configure Advanced Features, select SureConnect, and Click Go.
2. In the navigation pane, navigate to Security > Protection Features > SureConnect. In the details pane, click Parameters. In the Configure SureConnect Parameters window, browse and select the VSR filename.
3. Navigate to Traffic Management > Load Balancing > Services. In the details pane, click Add. In the **Create Services** window, enter the paramter values as shown in Table 5-1, and click **OK**.
4. Navigate to Traffic Management > Load Balancing > Virtual servers. In the details pane, click Add. In the Create Virtual Server (Load Balancing) dialog box, enter the values shown in Table 5.1 for the Load Balancing Virtual Server parameters and click OK.
5. In the navigation pane, navigate to Traffic Management > Load Balancing > Virtual servers. Select the virtual server vs-NSact and click Open in the details pane. The Configure Virtual system (Load Balancing) dialog box, displays the list of configured services. Select services psvc1 and psvc2 and click OK.
6. In the navigation pane, expand Security > Protection Features > SureConnect. In the details pane, click Add. Create the policy with the values as given in the parameters table.
7. In the navigation pane, navigate to Traffic Management > Load Balancing > Virtual servers. Select the virtual server vs-NSact and click Open in the details pane. In the Configure Virtual system (Load Balancing) dialog box, click the Policies

tab. Click >> to expand the features. Select **SureConnect**. When the list of SureConnect polices appear, select policyNS and click OK.

8. In the navigation pane, navigate to Traffic Management > Load Balancing > Virtual servers. Select the virtual server vs-NSact and click Open in the details pane. In the Configure Virtual system (Load Balancing) dialog box, on the Advanced tab, select SC and click OK.

You can configure the following SureConnect policies. The NetScaler appliance matches incoming requests in the order the policies are configured:

- Exact URL-based policies
- Wildcard rule-based policies

Configuring Exact URL Based Policies

Updated: 2013-09-03

When you configure an exact URL based policy, the NetScaler appliance matches the incoming request against the URL that has been configured in the policy. URL based policies take precedence over rule based policies.

At the command prompt, type:

add sc policy <name> [-url <URL> | -rule <expression>] [-delay <usecs>] [-maxConn <positive_integer>] [-action (ACS <altContentSvcName> <altContentPath>) | NS | NOACTION)]

1. Navigate to Security > Protection Features > SureConnect.
2. In the details pane, click Add.
3. In the Create SureConnect Policy dialog box, set the following parameters:
   - Name*
   - URL (Make sure that the URL check box is selected)
   - Value*
   - Delay (microseconds)*
   - Maximum Client Connections
   - Action (Select from the Choose Action list.)
   - Alternate Service Name (if you select ACS as the Action)
   - Alternate Content Path (if you select ACS as the Action)

   *A required parameter
4. Click Create, and click Close. The URL based policy appears in the right pane, and a message displays in the status bar that the policy is successfully configured.

Configuring Wildcard Rule-Based Policies

Updated: 2013-09-03

SureConnect matches the incoming requests to a defined rule, if you configure a rule-based policy.

1. Create the expression(s).

Use the add expression command to create each expression.

2. Create the rule(s).

   Use the add sc policy command with the -rule expression_logic argument to specify the rule(s). In the -rule expression_logic argument, refer to the expression(s) you created in step 1.

   Repeat this command to create and name each rule.

The following example creates a rule “rule = = /*.cgi”:

```
add vserver vs-lb http 1.1.1.1 80
add expression expr1 url == /cgi-bin/*.cgi
add expression expr2 url == /index.html
add sc policy surecpolicy1 -rule (expr1||expr2) -delay 1000000 -action NS
bind lb vserver vs-lb -policyName surecpolicy1
```

To complete the SureConnect configuration, you will need to enter additional commands, beyond those shown in the example.

1. Navigate to Security > Protection Features > SureConnect.
2. In the details pane, click Add.
3. In the Create SureConnect Policy dialog box, in the Name text box, type the name of the policy.
4. Under What to Monitor, click Expression, and then click Configure.
5. In the Create Expression dialog box, click Add.
6. In the Add Expression dialog box, enter an expression. For example, you can select an Expression Type of General, a Flow Type of REQ, a Protocol of HTTP, a Qualifier of URLQUERY, an Operator of CONTAINS, and in the Value text box, type AA. For more information about expressions, see "Policies and Expressions."
7. Click OK, and click Close.
8. In the Create Expression dialog box, click Create.

Examples of wildcard rules:

“/sports/*” matches all URLs under /sports

“/sports*” matches all URLs whose prefix matches “/sports”, starting at the beginning of the URL.

“/*.jsp” matches all URLs whose file extension is “jsp”

When configuring rule-based policies, first add the more specific rule-based policies, before adding more generic rules (for example, add /cgi-bin/sports*.cgi before adding /cgi-bin/*.cgi).

Displaying the Configured SureConnect Policy

To view the SureConnect policy that you have configured, at the NetScaler command prompt, enter the show sc policy command.

When SureConnect activates, it can display alternate content from one of the following files that you have configured:

- **progressbar.htm.** Displays the progress information.

- **alternatepage.htm.** Displays an alternate page.
- **barandpage.htm.** Displays both the progress information and an alternate page.

The alternate content files are JavaScript files. During SureConnect installation, these files are copied onto the server that contains the alternate content. These files can contain alternate content (including an alternate page) or references to other files that contain the alternate content.

This section describes the changes you can make to the alternate content file provided by the appliance.

```
//**** DEFINE YOUR VALUES HERE ****
var alt_url = "/Citrix NetScaler system /sample.gif";
var alt_url = "http://www.DomainName.com";
var Citrix NetScaler system _logo = "netscaler_logo.gif";
var our_logo = "netscaler_logo.gif";
var height = 450;
var width = 550;
var top = 200;
var left = 200;
var popunder = "no"; //specify yes for pop-under & no for pop-up
var shift_focus = "yes" //if you want to send pop-up to background on getting primary content else specify no
//**** YOUR DEFINITIONS ENDS HERE ****
```

You can make these changes:

- **var alt_url.** Specify the URL for the alternate content if a file provides the alternate content. For example:
  var alt_url = “/Citrix NetScaler system/sports.htm”
  Note: The alternate content file must be present in the /Citrix NetScaler system directory under the documents root of the Web server.
- **var our_logo.** Specify the image file of your organization logo.
- **var height.** Specify the height of the SureConnect window.
- **var width.** Specify the width of the SureConnect window.
- **var top and var left.** Specify the position of the SureConnect window.
- **var popunder.** Specifies the position of the alternate content window. Specify the value as NO to place the alternate content window above the original window. Specify the value as YES to place the alternate content window beneath the original window.
- **var shift_focus.** Specify the focus of the alternate content window. YES places the pop-up window in the background when getting the primary content. NO always keeps the pop-up window in focus, even when getting the primary content.

Note: For more information, see the README.txt file provided by the appliance with other alternate content files.

Updated: 2013-09-03

This section describes how SureConnect works in combination with the load balancing, content switching, cache redirection, and high availability features of the NetScaler appliance.

Configuring SureConnect for Load Balancing

You can use SureConnect in environments where the primary servers use the load balancing feature, with or without alternate servers. If the load balancing virtual server configured for SureConnect fails, the backup virtual server (if there is

one) handles the traffic. Backup virtual servers do not support SureConnect policies.

Note: For information about load balancing, see "Load Balancing."

Configuring SureConnect for Cache Redirection

You can use SureConnect in environments where cache redirection is configured. The primary server is a load balancing virtual server bound to the cache redirection virtual server. Regardless of any rules configured for the cache redirection feature:

- You can configure any URL for SureConnect.
- Once SureConnect is activated for a client, requests from the client are always sent to the origin server.

Configuring SureConnect for High Availability

SureConnect is compatible with NetScaler appliances operating in high availability mode.

Note: If the optional vsr.htm file is used, it must be present in both nodes (primary and secondary) and must use the same name and directory.

Activating SureConnect

Sep 03, 2013

You can set the Citrix NetScaler appliance to activate SureConnect if either of two criteria match. Both criteria are arguments to the add sc policy command, as described here:

- -delay <microseconds>

  The first time the client requests the URL, the appliance records how long the server takes to respond. The appliance will not activate SureConnect until the second time the URL is requested. The first and second requests may be from the same or different clients.

  If you set -delay argument, SureConnect will be activated the second time the delay reaches the threshold you set.

- -maxConn <positive_integer>

  When the appliance receives a request, it checks the number of connections to the server for the configured URL. SureConnect is activated if the number of connections is greater than or equal to the value that you set for the -maxConn argument.

  If you will be providing alternate content to be displayed in the client's Web browser, you should configure the -action argument of the add sc policy command. This specifies for the NetScaler appliance whether the alternate content is coming from a dedicated alternate server (-action ACS) or the appliance (-action NS).

  When SureConnect is activated by the –maxConn argument, the SureConnect window and progress bar are displayed in the client's browser (with an alternate page, if configured).

SureConnect Environments

Feb 13, 2017

The following topics describe SureConnect environments.

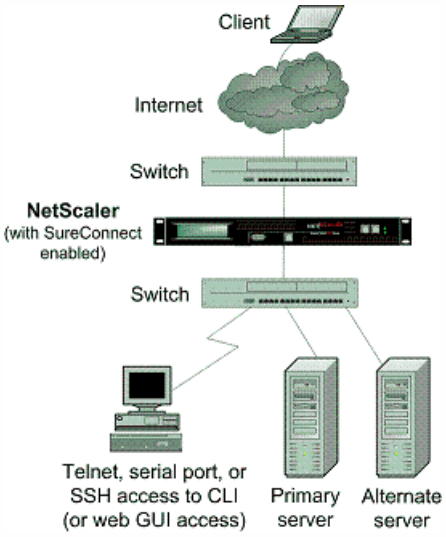
- Primary and Alternate Servers
- Configuration Checklist
- Example Configurations

The SureConnect environment uses a dedicated server to provide alternate content when the requested content is not available. The alternate content may include an alternate page, plus optional components such as frame set, organization logo, and so on. The alternate and primary servers can be the same server.

You can configure SureConnect to display a progress bar when the requested content is not available (or the progress bar and an alternate page).

The following figure illustrates the SureConnect environment.

Figure 1. SureConnect - Primary and Alternate Servers



Updated: 2013-09-03

Complete the following checklist before you start configuration:

Table 1. Configuration Checklist

▫	The same builds are running for the appliance and for the SureConnect files as suggested by appliance staff. Appliance Build Number: _____ SureConnect (sc_xx.exe) Build Number: _____

▫	The latest SureConnect files (style files) are extracted to: • All primary servers (required for NS action). • The alternate content server (required for ACS action).
▫	All customizations to the latest style and vsr.htm files are applied.
▫	The alternate content server is accessible from the Internet (required for ACS action).
▫	If the -redirectURL URL argument of the add vserver CLI command needs to be specified: • The URL is up and running. • This URL is not on the configured servers. • This URL does not match any content in the vserver (that is, do not redirect a missing URL to itself). Redirecting a missing URL to itself can send some browsers into an infinite loop.
▫	All URLs to be configured for SureConnect are top-level URLs only. (Only the URLs that occupy the whole window or frame can be configured, not the embedded objects).

Following are the steps to configure SureConnect in a setup with a primary server and a dedicated alternate server:

- Enable the SureConnect feature
- Add the SureConnect policy
- Bind the SureConnect policy

You can optionally configure the following:

- Redirect the client to another URL if the primary server fails, or send a customized response to the client if the alternate server fails.
- If the servers do not provide alternate content, send a default or customized response.

To redirect the client to another URL

1. Enable the SureConnect feature.
2. Define the primary server and its service.

   You must identify the original server for which SureConnect support is being configured. At the NetScaler command prompt, type the following command:

   add service <serviceName> <IP> HTTP <port>
   where <serviceName> assigns a name for the service; <IP> is the server's IP address; and <port> is the port number that the service will use.

   Repeat use of the add service CLI command for each service that is to be added.

   You can also configure SureConnect on a load balancing virtual server. At the NetScaler command prompt, type the following command:

add vserver <name> HTTP <IP> <port>

3. Define and bind the SureConnect policy as follows. If you are configuring a rule-based policy, perform this step as described in "Configuring Wildcard Rule-Based Policies." To configure a URL-based policy, at the NetScaler command prompt, type the following command:

   add sc policy <name> [-url <URL>] [-delay <microsec>] [-maxConn <positiveInteger>]
   For a detailed description of the add sc policy command, see "Command Reference."

   To bind the SureConnect policy, at the NetScaler command prompt, type the following command:

   bind service <serviceName> -policyname <string>
   where <serviceName> is the name of the service defined in step 2, and <string> is the name of the SureConnect policy.

   Repeat the bind service command for each policy created.

   You must include the alternate content page in the altContSvcName argument, and in the altContPath argument of the add sc policy command.

   In the following example, the name of the alternate content file is /Citrix NetScaler system /barandpage.htm, and this file resides in svc2.

4. To save the configuration, at the NetScaler command prompt, type the following command:
   save config

Updated: 2013-09-03

The following examples illustrate various SureConnect configurations.

The examples assume that monitoring of physical services is enabled. If the alternate system is down, SureConnect will deliver the alternate content from the system itself.

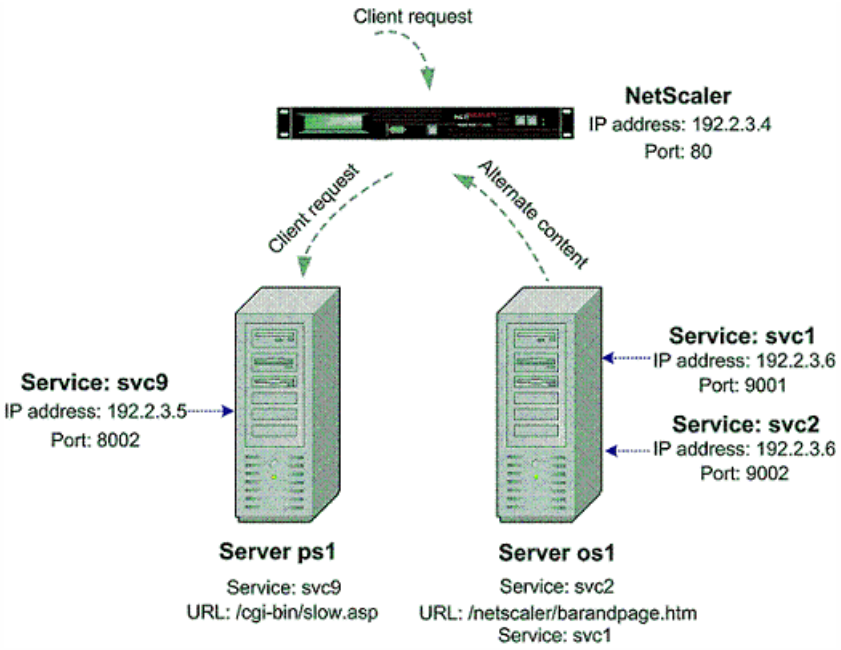
Example 1 - SureConnect Progress Bar and Alternate Page

You can configure SureConnect to display both the progress bar and an alternate page to the user.

To bind a SureConnect policy to a load balancing virtual server, at the command prompt, type the following commands:

bind lb vserver <virtualServerName> -policyName <string>
where <virutalServerName> is the name of the load balancing virtual server defined in step 2 of the configuration process, and <string> is the name of the SureConnect policy defined in step 3.

Figure 2. SureConnect Configuration - Example 1



At the NetScaler command prompt, type the following commands:

```
enable feature SC
show ns info
add service svc2 192.2.3.6 HTTP 9002
show server
show service svc2
add service svc9 192.2.3.5 HTTP 8002
add sc policy policy8 -url /cgi-bin/slow.asp
-delay 3000000 -action ACS svc2 /NetScaler 9000 system barandpage.htm
bind service svc9 -policyname policy8
set service svc9 -sc ON
save config
```

After you configure SureConnect, you can enter commands that show information to verify what you have configured.

Example 2 - SureConnect Progress Bar Only

In this example, SureConnect will display only the progress bar. The server orgsrvr with IP address 10.101.8.187 has service orgsvc. This server is connected to the appliance. The service is bound to the appliance. The progressbar.htm file specifies that only the progress bar will be displayed.

At the NetScaler command prompt, type the following commands:

```
enable feature SC
add service orgsvc 10.101.3.187 HTTP 80
add sc policy policy9 -url /cgi-bin/slow.asp
-delay 4000000 -action ACS orgsvc /NetScaler 9000 system / progressbar.htm
bind service orgsvc -policyname policy9
set service orgsvc -sc ON
save config
```

Example 3 - SureConnect with Load Balancing

This example illustrates how to configure the load balancing feature so that SureConnect will display alternate contents from the primary server. For information about load balancing, see "Load Balancing."

In this example, two physical servers with IP 10.101.3.187 and 10.101.3.188 are being load balanced by the appliance. The name and location of the alternate page file is specified in the file alternatepage.htm, which resides on both servers.

The appliance has one configured virtual server address: 10.101.3.201. At the NetScaler command prompt, type the following commands:

```
enable feature SC LB
add service psvc1 10.101.3.187 HTTP 80
add service psvc2 10.101.3.188 HTTP 80
add vserver vs-SureC HTTP 10.101.3.201 80
bind lb vserver vs-SureC psvc1
bind lb vserver vs-SureC psvc2
add sc policy policy9 -url /cgi-bin/slow.asp -delay 4000000
-action ACS vs-SureC /NetScaler system /alternatepage.htm
bind lb vserver vs-SureC -policyName policy9
set lb vserver vs-SureC -sc ON
save config
```

Example 4 - SureConnect with Load Balancing (ACS Action)

This example illustrates how to configure the NetScaler appliance load balancing feature so that SureConnect will display alternate content from the alternate server. For information about load balancing, see "Load Balancing."

In this case, there are two physical servers, IP 10.101.3.187 and 10.101.3.188. Both are being load balanced by the appliance.

The name and location of the alternate page file are specified in file barandpage.htm, which resides on a third server not being load balanced.

The third server's IP address is 10.101.3.189. Because barandpage.htm is specified, the progress bar and alternate page will both be displayed.

The appliance has one configured virtual server "vsvr" whose IP address (Virtual Server) is 10.101.3.200.

At the NetScaler command prompt, type the following commands:

```
enable feature SC LB
add service psvc1 10.101.3.187 HTTP 80
add service psvc2 10.101.3.188 HTTP 80
add service alt-cont-svc 10.101.3.189 HTTP 80
add vserver vsvr HTTP 10.101.3.200 80
bind lb vserver vsvr psvc1
bind lb vserver vsvr psvc2
add sc policy policy10 -url /cgi-bin/slow.asp
-delay 4000000 -action ACS alt-cont-svc
```

/NetScaler 9000 system /barandpage.htm
bind lb vserver vsvr -policyName policy10
set lb vserver vsvr -sc ON
save config

Example 5 - SureConnect with Content Switching

This example illustrates how to configure SureConnect where the NetScaler content switching and load balancing features are being used. SureConnect is configured on a load balancing virtual server bound to a content switching virtual server.

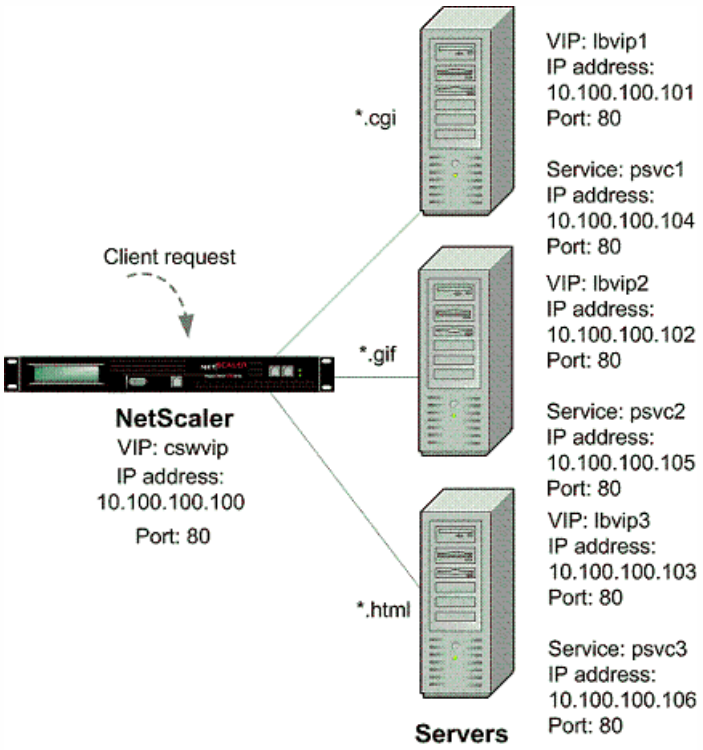
The alternate content is distributed under the content switching virtual server according to the content switching rules. For more information about load balancing and content switching, see "Load Balancing" and "Content Switching."

In this case, three physical services with IP addresses 10.100.100.104, 10.100.100.105, and 10.100.100.106 are bound to three load balancing virtual servers with IP addresses 10.100.100.101, 10.100.100.102, and 10.100.100.103. These three load balancing virtual servers are bound to a content switching virtual server with IP address 10.100.100.100.

In this setup, lbvip1 contains .cgi content, lbvip2 contains .gif content, and .lbvip3 contains .html content.

The name and location of the alternate page file is specified in the file alternatepage.htm, which resides on lbvip3. The embedded objects in this file must be distributed according to the content switching rules (any embedded gif will reside on lbvip2, any embedded htm will reside on lbvip3, and so on).

Figure 3. SureConnect Configuration - Example 5



At the NetScaler command prompt, type the following commands:

enable feature CS LB SC
add vserver cswvip HTTP 10.100.100.100 80 -type CONTENT
add vserver lbvip1 HTTP 10.100.100.101 80 -type ADDRESS

```
add vserver lbvip2 HTTP 10.100.100.102 80 -type ADDRESS
add vserver lbvip3 HTTP 10.100.100.103 80 -type ADDRESS
add service psvc1 10.100.100.104 HTTP 80
add service psvc2 10.100.100.105 HTTP 80
add service psvc3 10.100.100.106 HTTP 80
bind lb vserver lbvip1 psvc1
bind lb vserver lbvip2 psvc2
bind lb vserver lbvip3 psvc3
add cs policy CSWpolicy1 -url /*.cgi
bind cs vserver cswvip lbvip1 -policyName CSWpolicy1
add cs policy CSWpolicy2 -url /*.gif
bind cs vserver cswvip lbvip2 -policyName CSWpolicy2
add cs policy CSWpolicy3 -url /*.htm
bind cs vserver cswvip lbvip3 -policyName CSWpolicy3
add sc policy SCpol -url /cgi-bin/delay.cgi -delay 4000000 -action ACS cswvip /alternatepage.htm
bind lb vserver lbvip1 -policyName SCpol
set lb vserver lbvip1 -sc ON
save config
```

Surge Protection

Mar 21, 2012

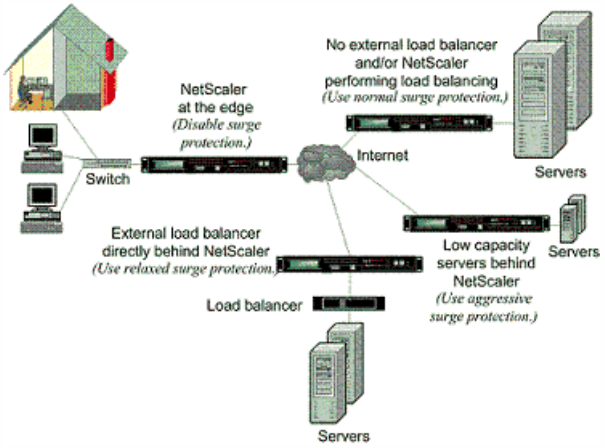
When a surge in client requests overloads a server, server response becomes slow, and the server is unable to respond to new requests. The Surge Protection feature ensures that connections to the server occur at a rate that the server can handle. The response rate depends on how surge protection is configured. The NetScaler appliance also tracks the number of connections to the server, and uses that information to adjust the rate at which it opens new server connections.

Surge protection is enabled by default. If you do not want to use surge protection, as will be the case with some special configurations, you must disable it.

The default surge protection settings are sufficient for most uses, but you can configure surge protection to tune it for your needs. First, you can set the throttle value to tell it how aggressively to manage connection attempts. Second you can set the base threshold value to control the maximum number of concurrent connections that the NetScaler appliance will allow before triggering surge protection. (The default base threshold value is set by the throttle value, but after setting the throttle value you can change it to any number you want.)

The following figure illustrates how surge protection is configured to handle traffic to a Web site.

Figure 1. A Functional Illustration of NetScaler Surge Protection



Note: If the NetScaler appliance is installed at the edge of the network, where it interacts with network devices on the client side of the Internet, the surge protection feature must be disabled. Surge protection must also be disabled if you enable USIP (Using Source IP) mode on your appliance.

The following example and illustration show the request and response rates for two cases. In one case, surge protection is disabled, and in the other it is enabled.

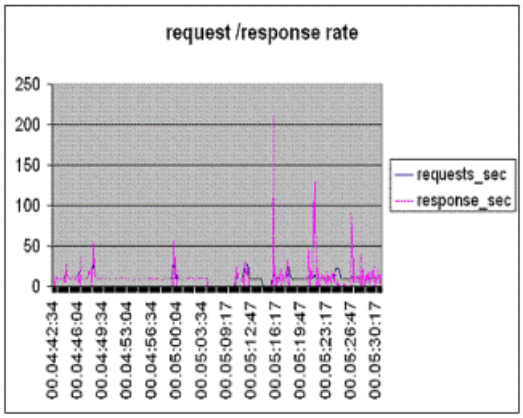
When surge protection is disabled and a surge in requests occurs, the server accepts as many requests as it can process concurrently, and then begins to drop requests. As the server becomes more overloaded, it goes down and the response rate is reduced to zero. When the server recovers from the crash, usually several minutes later, it sends resets for all pending requests, which is abnormal behavior, and also responds to new requests with resets. The process repeats for each surge in requests. Therefore, a server that is under DDoS attack and receives multiple surges of requests can become unavailable to legitimate users.

When surge protection is enabled and a surge in requests occurs, surge protection manages the rate of requests to the server, sending requests to the server only as fast as the server can handle those requests. This enables the server to respond to each request correctly in the order it was received. When the surge is over, the backlogged requests are cleared

as fast as the server can handle them, until the request rate matches the response rate.

The following figure compares the request and response scenarios when surge protection is enabled to that when it is disabled.

Figure 2. Request/Response Rate with and without Surge Protection



Disabling and Reenabling Surge Protection

Sep 03, 2013

The surge protection feature is enabled by default. When surge protection is enabled, it is active for any service that you add.

At the command prompt, type one of the following sets of commands to disable or reenable surge protection and verify the configuration:

- disable ns feature SurgeProtection
- show ns feature

- enable ns feature SurgeProtection
- show ns feature

Example

```
disable ns feature SurgeProtection
 Done show ns feature

      Feature                Acronym          Status
      -------                -------          ------
 1)   Web Logging             WL               ON
 2)   Surge Protection        SP               OFF
 .
 .
 .
 23)  HTML Injection          HTMLInjection    ON
 24)  NetScaler Push          push             OFF
 Done
 enable ns feature SurgeProtection
 Done
> show ns feature

      Feature                Acronym          Status
      -------                -------          ------
 1)   Web Logging             WL               ON
 2)   Surge Protection        SP               ON
 .
 .
 .

 23)  HTML Injection          HTMLInjection    ON
 24)  NetScaler Push          push             OFF
 Done
>
```

1. In the navigation pane, expand System, and then select Settings.
2. In the details pane, click Change Advanced Features.
3. In the Configure Advanced Features dialog box, clear the selection from the Surge Protection check box to disable the surge protection feature, or select the check box to enable the feature.
4. Click OK.
5. In the Enable/Disable Feature(s) dialog box, click Yes. A message appears in the status bar, stating that the feature has been enabled or disabled.

1. Navigate to Traffic Management > Load Balancing > Services. The list of configured services is displayed in the details pane.
2. In the details pane, select the service for which you want to disable or reenable the surge protection feature, and then click Open.
3. In the Configure Service dialog box, click the Advanced tab and scroll down.
4. In the Others frame, clear the selection from the Surge Protection check box to disable the surge protection feature, or select the check box to enable the feature.
5. Click OK. A message appears in the status bar, stating that the feature has been enabled or disabled.
   Note: Surge protection works only when both the feature and the service setting are enabled.

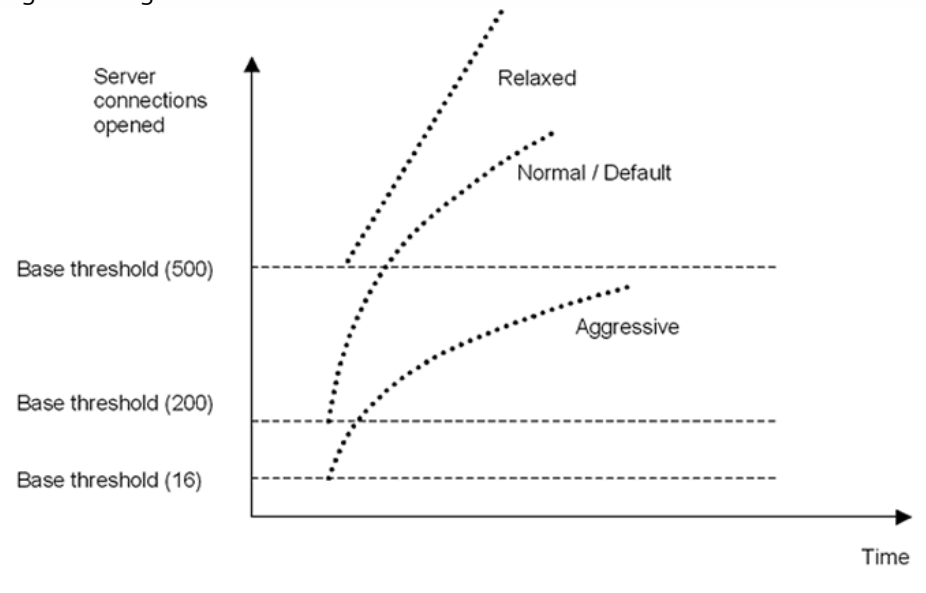
Setting Thresholds for Surge Protection

May 14, 2012

To set the rate at which the NetScaler appliance opens connections to the server, you must configure the threshold and throttle values for surge protection.

The following figure shows the surge protection curves that result from setting the throttle rate to relaxed, normal, or aggressive. Depending on the configuration of the server capacity, you can set base threshold values to generate appropriate surge protection curves.

Figure 1. Surge Protection Curves

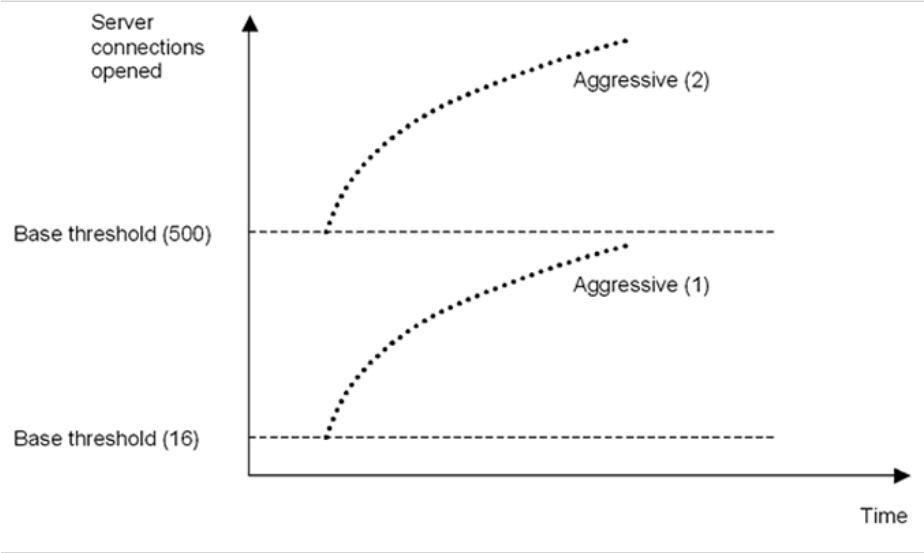


Your configuration settings affect the behavior of surge protection in the following manner:

- If you do not specify a throttle rate, it is set to normal (the default value), and the base threshold is set to 200, as shown in the preceding figure.
- If you specify a throttle rate (aggressive, normal, or relaxed) without specifying a base threshold, the curve reflects the default values of the base threshold for that throttle rate. For example, if you set the throttle rate to relaxed, the resulting curve will have the base threshold value of 500.
- If you specify only the base threshold, the entire surge protection curve shifts up or down, depending on the value you specify, as shown in the figure that follows.
- If you specify both a base threshold and a throttle rate, the resulting surge protection curve is based on the set throttle rate and adjusted according to the value set for the base threshold.

In the following figure, the lower curve (Aggressive 1) results when the throttle rate is set to aggressive but the base threshold is not set. The upper curve (Aggressive 2) results when the base threshold is set to 500, but the throttle rate is not set. The second upper curve (Aggressive 2) also results when the base threshold is set to 500, and the throttle rate is set to aggressive.

Figure 2. Aggressive Rate with the Default or a Set Base Threshold



To set the threshold for surge protection by using the configuration utility

1. In the navigation pane, expand System, and then select Settings.
2. In the details pane, click Global System Settings.
3. If you want to set a base threshold different from the default for the throttle rate, in the Configure Global Settings dialog box, Base Threshold text box, enter the maximum number of concurrent server connections allowed before surge protection is triggered. The base threshold is the maximum number of server connections that can be open before surge protection is activated. The maximum value for this setting is 32,767 server connections. The default setting for this value is controlled by the throttle rate you choose in the next step.
   Note: If you do not set an explicit value here, the default value will be used.
4. In the Throttle drop-down list, select a throttle rate. The throttle is the rate at which the NetScaler appliance allows connections to the server to be opened. The throttle can be set to the following values:
   Aggressive
   Choose this option when the connection-handling and surge-handling capacity of the server is low and the connection needs to be managed carefully. When you set the throttle to aggressive, the base threshold is set to a default value of 16, which means that surge protection is triggered whenever there are 17 or more concurrent connections to the server.
   Normal
   Choose this option when there is no external load balancer behind the NetScaler appliance or downstream. The base threshold is set to a value of 200, which means that surge protection is triggered whenever there are 201 or more concurrent connections to the server. Normal is the default throttle option.
   Relaxed
   Choose this option when the NetScaler appliance is performing load balancing between a large number of Web servers, and can therefore handle a high number of concurrent connections. The base threshold is set to a value of 500, which means that surge protection is triggered only when there are 501 or more concurrent connections to the server.
5. Click OK. A message appears in the status bar, stating that the global settings are configured.

Flushing the Surge Queue

Dec 04, 2013

When a physical server receives a surge of requests, it becomes slow to respond to the clients that are currently connected to it, which leaves users dissatisfied and disgruntled. Often, the overload also causes clients to receive error pages. To avoid such overloads, the NetScaler appliance provides features such as surge protection, which controls the rate at which new connections to a service can be established.

The appliance does connection multiplexing between clients and physical servers. When it receives a client request to access a service on a server, the appliance looks for an already established connection to the server that is free. If it finds a free connection, it uses that connection to establish a virtual link between the client and the server. If it does not find an existing free connection, the appliance establishes a new connection with the server, and establishes a virtual link between client and the server. However, if the appliance cannot establish a new connection with the server, it sends the client request to a surge queue. If all the physical servers bound to the load balancing or content switching virtual server reach the upper limit on client connections (max client value, surge protection threshold or maximum capacity of the service), the appliance cannot establish a connection with any server. The surge protection feature uses the surge queue to regulate the speed at which connections are opened with the physical servers. The appliance maintains a different surge queue for each service bound to the virtual server.

The length of a surge queue increases whenever a request comes for which the appliance cannot establish a connection, and the length decreases whenever a request in the queue gets sent to the server or a request gets timed out and is removed from the queue.

If the surge queue for a service or service group becomes too long, you may want to flush it. You can flush the surge queue of a specific service or service group, or of all the services and service groups bound to a load balancing virtual server. Flushing a surge queue does not affect the existing connections. Only the requests present in the surge queue get deleted. For those requests, the client has to make a fresh request.

You can also flush the surge queue of a content switching virtual server. If a content switching virtual server forwards some requests to a particular load balancing virtual server, and the load balancing virtual server also receives some other requests, when you flush the surge queue of the content switching virtual server, only the requests received from this content switching virtual server are flushed; the other requests in the surge queue of the load balancing virtual server are not flushed.

Note: You cannot flush the surge queues of cache redirection, authentication, VPN or GSLB virtual servers or GSLB services.
Note: Do not use the Surge Protection feature if Use Source IP (USIP) is enabled.

The flush ns surgeQ command works in the following manner:

- You can specify the name of a service, service group, or virtual server whose surge queue has to be flushed.
- If you specify a name while executing the command, surge queue of the specified entity will be flushed. If more than one entity has the same name, the appliance flushes surge queues of all those entities.
- If you specify the name of a service group, and a server name and port while executing the command, the appliance flushes the surge queue of only the specified service group member.
- You cannot directly specify a service group member (<serverName> and <port>) without specifying the name of the service group (<name>) and you cannot specify <port> without a <serverName>. Specify the <serverName> and <port> if you want to flush the surge queue for a specific service group member.
- If you execute the command without specifying any names, the appliance flushes the surge queues of all the entities present on the appliance.
- If a service group member is identified with a server name, you must specify the server name in this command; you cannot specify its IP address.

At the command prompt, type:

flush ns surgeQ [-name <name>] [-serverName <serverName> <port>]

Examples

1.

flush ns surgeQ –name SVC1ANZGB –serverName 10.10.10.1 80

The above command flushes the surge queue of the service or virtual server that is named SVC1ANZGB and has IP address as 10.10.10

2.

flush ns surgeQ

The above command flushes all the surge queues on the appliance.

Navigate to Traffic Management > Content Switching > Virtual Servers, select a virtual server and, in the Action list, select Flush Surge Queue.

DNS Security Options

Dec 27, 2016

Note: This feature was introduced in NetScaler release 11.1 build 51.x.

You can now configure the DNS security options from the Add DNS Security Profile page in the NetScaler GUI. To configure the DNS security options from the NetScaler CLI or the NITRO API, use the AppExpert components. For instructions, see the NITRO API documentation and the NetScaler Command Reference Guide.

One option, cache poisoning protection, is enabled by default and cannot be disabled. You can apply the other options to all DNS endpoints or to specific DNS virtual servers in your deployment, as shown in the following table:

Security option	Can be applied to all DNS endpoints?	Can be applied to specific DNS virtual servers?
DNS DDoS protection	Yes	Yes
Manage exceptions – whitelist/blacklist servers	Yes	Yes
Prevent random subdomain attacks	Yes	Yes
Bypass the cache	Yes	No
Enforce DNS transactions over TCP	Yes	Yes
Provide root details in the DNS response	Yes	No

A cache poisoning attack redirects users from legitimate sites to malicious websites.

For example, the attacker replaces a genuine IP address in the DNS cache with a fake IP address that they control. When the server responds to requests from these addresses, the cache is poisoned and the subsequent requests for the addresses of the domain are redirected to the attacker's site.

The Cache Poisoning Protection option prevents insertion of corrupt data into the database that caches DNS server requests and responses. This is an inbuilt feature of the NetScaler appliances and is always enabled.

You can configure the DNS DDoS Protection option for each type of request that you suspect might be used in a DDoS attack. For each type, the NetScaler appliance drops any requests received after a threshold value for the number of requests received in a specified period of time (time slice) is exceeded. You can also configure this option to log a warning to the SYSLOG server. For example:

- **DROP** - Assume that you have enabled A record protection with threshold value 15, time slice as 1 second and chosen DROP. When the incoming requests exceed 15 in 1 second, then the packets start getting dropped.
- **WARN** - Assume that you have enabled A record protection with threshold value 15, time slice as 1 second and chosen

WARN. When the incoming requests exceeds around 15 queries in 1 second, a warning message is logged indicating a threat and then the packets start getting dropped. It is recommended to set threshold values for WARN smaller than that of DROP for a record type. This will help administrators identify an attack by logging a warning message before the actual attack happens and NetScaler starts dropping incoming requests.

To set a threshold for incoming traffic by using the NetScaler GUI

1. Navigate to **Configuration** > **Security** > **DNS Security**.
2. On the **DNS Security Profile** page, click **Add**.
3. On the **Add DNS Security Profile** page, do the following:
4. Expand **DNS DDoS Protection**.
   1. Select the record type and enter the threshold limit and the time slice value.
   2. Select **DROP** or **WARN**.
   3. Repeat steps a and b for each of the other record types that you want to protect against.
5. Click **Submit**.

Manage excepts enables you to add exceptions either to blacklist or whitelist domain name and IP addresses. For example:

- When a particular IP address is identified posting an attack, such IP address can be blacklisted.
- When administrators find that there is unexpectedly high request for a particular domain name, then that domain name can be blacklisted.
- NXDomains and some of the existent domains which can consume the server resources can be blacklisted.
- When administrators whitelist domain names or IP addresses, queries or requests only from these domains or IP addresses are answered and all others are dropped.

To create a whitelist or blacklist by using the NetScaler GUI

1. Navigate to **Configuration** > **Security** > **DNS Security**.
2. On the **DNS Security Profiles** page, click **Add**.
3. On the **Add DNS Security Profile** page, do the following:
   1. Expand **Manage exceptions – Whitelist/Blacklist Servers**.
   2. Select **Block** to block queries from blacklisted domains/addresses, or select **Allow** only to allow queries from whitelisted domains/addresses.
   3. In the **Domain name / IP Address** box, enter the domain names, IP addresses, or IP address ranges. Use commas to separate the entries.
      Note: If you select **Advanced Option**, you can use the “start with,” “contains,” and “ends with” options to set the criteria.
      For example, you can set criteria to block a DNS query that starts with “image” or ends with “.co.ru” or contains “mobilesites.”
4. Click **Submit**.

In random subdomain attacks, queries are sent to random, nonexistent subdomains of legitimate domains. This increases the load on the DNS resolvers and servers. As a result, they can become overloaded and slow down.

The Prevent Random Subdomain Attacks option directs the DNS responder to drop DNS queries that exceed a specified length.

Assume that example.com is a domain name owned by you and hence the resolution request comes to your DNS server. The attacker can append a random subdomain to example.com and send a request. Based on the specified query length and the FQDN, the random queries will be dropped.

For example, if the query is www.image987trending.example.com, it will be dropped if the query length is set to 20.

To specify a DNS query length by using the NetScaler GUI

1. Navigate to **Configuration** > **Security** > **DNS Security**.
2. On the **DNS Security Profiles** page, click **Add**.
3. On the **Add DNS Security Profile** page, do the following:
   1. Expand **Prevent Random Subdomain Attacks**.
   2. Enter the numerical value for the query length.
4. Click **Submit**.

During an attack, the data that is already cached must be protected. To protect the cache, new requests for certain domains or record types or response codes can be sent to the origin servers instead of cached.

The Bypassing the cache option directs the NetScaler appliance to bypass the cache for specified domains, record types, or response codes when an attack is detected.

To bypass the cache for specified domains or record types or response types by using the NetScaler GUI

1. Navigate to **Configuration** > **Security** > **DNS Security**.
2. On the **DNS Security Profiles** page, click **Add**.
3. On the **Add DNS Security Profile** page, expand **Bypassing the cache** and enter the domain names and / or choose the record types or the response types for which the cache has to be bypassed.
   - Click **Domains** and enter the domain names. Use commas to separate the entries.
   - Click **Record Types** and choose the record types.
   - Click **Response Types** and choose the response type.
4. Click **Submit**.

Some DNS attacks can be prevented if the transactions are forced to use TCP instead of UDP. For example, during a bot attack, the client sends a flood of queries but cannot handle responses. If the use of TCP is enforced for these transactions, then the bots cannot understand the responses and therefore cannot send requests over TCP.

To force domains or record types to operate at the TCP level by using the NetScaler GUI

1. Navigate to **Configuration** > **Security** > **DNS Security**.
2. On the **DNS Security Profiles** page, click **Add**.
3. On the **Add DNS Security Profile** page, expand **Enforce DNS Transactions over TCP** and enter the domain names and / or choose the record types for which the DNS transactions must be enforced over TCP.
   - Click **Domains** and enter the domain names. Use commas to separate the entries.
   - Click **Record Types** and choose the record types.
4. Click **Submit**.

In some attacks, the attacker sends a flood of queries for unrelated domains that are not configured or cached on the NetScaler appliance. If the dnsRootReferral parameter is ENABLED, it exposes all the root servers.

The Provide Root Details in the DNS Response option directs the NetScaler appliance to restrict access to root referrals for a query that is not configured or cached. The appliance sends a blank response.

The Provide Root Details in the DNS Response option can also mitigate or block amplification attacks. When the dnsRootReferral parameter is DISABLED, there will be no root referral in the NetScaler responses and hence they do not get amplified.

To enable or disable access to the root server by using the NetScaler GUI

1. Navigate to **Configuration** > **Security** > **DNS Security**.
2. On the **DNS Security Profiles** page, click **Add**.
3. On the **Add DNS Security Profile** page, do the following:
   1. Expand **Provide Root Details in the DNS Response**.
   2. Click **ON** or **OFF** to allow or restrict access to the root server.
4. Click **Submit**.

System

Jul 01, 2016

This section provides system-level information of the NetScaler ADC. This includes a detailed explanation of system-level features, the scenarios in which the features can be used, the configuration steps, and examples to help you better understand the features.

- Basic Operations
- Authentication and Authorization
- TCP Configurations
- HTTP Configurations
- SNMP
- Audit Logging
- Web Server Logging
- Call Home
- Reporting Tool
- AutoScale
- CloudBridge Connector
- High Availability
- TCP Optimization

Basic Operations

Jun 02, 2015

Any changes you make to the configuration of a NetScaler appliance are not saved automatically. You have to save the settings manually. When an appliance is restarted, it loads the latest saved configuration.

This document includes the following details:

- Viewing and Saving Configurations
- Clearing the NetScaler Configuration

Viewing and Saving Configurations

Configurations are stored in the /nsconfig/ns.conf directory. For configurations to be available across sessions, you must save the configuration after every configuration change.

To view the running configuration by using the command line interface

At the command prompt, type:

show ns runningConfig

To view the running configuration by using the configuration utility

- Navigate to System > Diagnostics and, in the View Configuration group, click Running Configuration.

To find the difference between two configuration files by using the command line interface

At the command prompt, type:

diff ns config <configfile1> <configfile2>

To find the difference between two configuration files by using the configuration utility

- Navigate to System > Diagnostics and, in the View Configuration group, click Configuration difference.

To save configurations by using the command line interface

At the command prompt, type:

save ns config

To save configurations by using the configuration utility

On the Configuration tab, in the top-right corner, click the Save icon.

To view the saved configurations by using the command line interface

At the command prompt, type:

show ns ns.conf

To view the saved configurations by using the configuration utility

Navigate to System > Diagnostics and, in the View Configuration group, click Saved Configuration.

Clearing the NetScaler Configuration

You have the following three options for clearing the NetScaler configuration.

Basic level. Clearing your configuration at the basic level clears all settings except the following:

- NSIP, MIP(s), and SNIP(s)
- Network settings (Default Gateway, VLAN, RHI, NTP, and DNS settings)
- HA node definitions
- Feature and mode settings
- Default administrator password (nsroot)

Extended level. Clearing your configuration at the extended level clears all settings except the following:

- NSIP, MIP(s), and SNIP(s)
- Network settings (Default Gateway, VLAN, RHI, NTP, and DNS settings)
- HA node definitions

Feature and mode settings revert to their default values.

Full level. Clearing your configuration at the full level returns all settings to their factory default values. However, the NSIP and default gateway are not changed, because changing them could cause the appliance to lose network connectivity.

To clear the configuration by using the command line interface

At the command prompt, type:

clear ns config -force <level>

Example: To forcefully clear the basic configurations on an appliance.

```
clear ns config -force basic
```

To clear the configuration by using the configuration utility

- Navigate to System > Diagnostics and, in the Maintenance group, click Clear Configuration and select the configuration level to be cleared from the appliance.

Configuring Clock Synchronization

Jun 02, 2015

You can configure your NetScaler appliance to synchronize its local clock with a Network Time Protocol (NTP) server. This ensures that its clock has the same date and time settings as the other servers on your network.

You can configure clock synchronization on your appliance by adding NTP server entries to the ntp.conf file from either the configuration utility or the command line interface, or by manually modifying the ntp.conf file and then starting the NTP daemon (NTPD). The clock synchronization configuration does not change if the appliance is restarted, upgraded, or downgraded. However, the configuration does not get propagated to the secondary NetScaler in a high availability setup.

Note: If you do not have a local NTP server, you can find a list of public, open access, NTP servers at the official NTP site, http://www.ntp.org, under Public Time Servers List. Before configuring your NetScaler to use a public NTP server, be sure to read the Rules of Engagement page (link included on all Public Time Servers pages).
In NetScaler release 11, the NTP version has been updated from 4.2.6p3 to 4.2.8p2.
This document includes the following details:

- Setting Up Clock Synchronization
- Starting the NTP Daemon
- Configuring Clock Synchronization Manually

Setting Up Clock Synchronization

To configure clock synchronization, you must add NTP servers and then enable NTP synchronization.

To add an NTP server by using the command line interface

At the command prompt, type the following commands to add an NTP server and verify the configuration:

- add ntp server (<serverIP> | <serverName>) [-minpoll <positive_integer>] [-maxpoll <positive_integer>]
- show ntp server

Example

```
> add ntp server 10.102.29.30 -minpoll 6 -maxpoll 11
```

To configure an NTP server by using the configuration utility

Navigate to System > NTP Servers, and create the NTP server.

Starting the NTP Daemon

When you enable NTP synchronization, the NetScaler starts the NTP daemon and uses the NTP server entries in the ntp.conf file to synchronize its local time setting. If you do not want to synchronize the appliance time with the other servers in the network, you can disable NTP synchronization, which stops the NTP daemon (NTPD).

To enable NTP synchronization by using the command line interface

At the command prompt, type one of the following commands:

enable ntp sync

To enable NTP synchronization by using the configuration utility

Navigate to System > NTP Servers, click Action and select NTP Synchronization.

Configuring Clock Synchronization Manually

You can configure clock synchronization manually by logging on to the NetScaler appliance and editing the ntp.conf file.

To enable clock synchronization on your NetScaler appliance by modifying the ntp.conf file

1. Log on to the command line interface.
2. Switch to the shell prompt.
3. Copy the /etc/ntp.conf file to /nsconfig/ntp.conf, unless the /nsconfig directory already contains an ntp.conf file.
4. For each NTP server you want to add, you must add the following two lines to the /nsconfig/ntp.conf file:

   server <IP address for NTP server> **iburst**

   restrict <IP address for NTP server> **mask** <netmask> **nomodify notrap nopeer noquery**

   Note: For security reasons, there should be a corresponding restrict entry for each server entry.

   Example
   In the following example, an administrator has inserted # characters to "comment out" an existing NTP entry, and then added a new entry:

   #server 1.2.3.4 iburst

   #restrict 1.2.3.4 mask 255.255.255.255 nomodify notrap nopeer noquery

   server 10.102.29.160 iburst

   restrict 10.102.29.160 mask 255.255.255.255 nomodify notrap nopeer noquery

5. If the /nsconfig directory does not contain a file named rc.netscaler, create the file.

6. Add the following entry to /nsconfig/rc.netscaler: **/bin/sh /etc/ntpd_ctl full_start**

   This entry starts the ntpd service, checks the ntp.conf file, and logs messages in the /var/log directory.

   This process runs every time the NetScaler is restarted.

7. Restart the NetScaler appliance to enable clock synchronization. Or, to start the time synchronization process without restarting the appliance, enter the following commands at the shell prompt:

- rm /etc/ntp.conf
- ln -s /nsconfig/ntp.conf /etc/ntp.conf
- /bin/sh /etc/ntpd_ctl full_start

Configuring System Session Timeout

Sep 12, 2014

A session timeout interval is provided to restrict the time duration for which a session (GUI, CLI, or API) remains active when not in use. For the NetScaler, the system session timeout can be configured at the following levels:

- **User level timeout.** Applicable to the specific user.

GUI	Navigate to System > User Administration > Users, select a user, and edit the user's timeout setting.
CLI	At the command prompt, enter the following command: set system user <name> -timeout <secs>

- **User group level timeout.** Applicable to all users in the group.

GUI	Navigate to System > User Administration > Groups, select a group, and edit the group's timeout setting.
CLI	At the command prompt, enter the following command: set system group <groupName> -timeout <secs>

- **Global system timeout.** Applicable to all users and users from groups who do not have a timeout configured.

GUI	Navigate to System > Settings, click Change global system settings, and update the timeout value as required.
CLI	At the command prompt, enter the following command: set system parameter -timeout <secs>

The timeout value specified for a user has the highest priority. If timeout is not configured for the user, the timeout configured for a member group is considered. If timeout is not specified for a group (or the user does not belong to a group), the globally configured timeout value is considered. If timeout is not configured at any level, the default value of 900 seconds is set as the system session timeout.

Additionally, you can specify timeout durations for each of the interfaces you are accessing. However, the timeout value specified for a specific interface is restricted to the timeout value configured for the user that is accessing the interface. For example, let us consider an user "publicadmin" who has a timeout value of 20 minutes. Now, when accessing an interface, the user must specify a timeout value that is within 20 minutes.

Note: You can choose to keep a check on the minimum and maximum timeout values by specifying the timeout as restricted (in CLI by specifying the restrictedTimeout parameter). This parameter is provided to account for previous NetScaler versions where the timeout value was not restricted.

- When enabled, the minimum configurable timeout value is 5 minutes (300 secs) and the maximum value is 1 day (86400 secs). If the timeout value is already configured to a value larger than 1 day, when this parameter is enabled, you are prompted to change it. If you do not change the value, the timeout value will automatically be reconfigured to the default timeout duration of 15 minutes (900 secs) on next reboot. The same will happen is the configured timeout value is less than 5 minutes.
- When disabled, the configured timeout durations are considered.

To configure the timeout duration at each interface:

NetScaler user interface	Timeout configuration
CLI	Specify the timeout value on the command prompt by using the following command: set cli mode -timeout <secs>
API	Specify the timeout value in the login payload.

Viewing the System Date and Time

Aug 08, 2014

To change the system date and time, you must use the shell interface to the underlying FreeBSD OS. However, to view the system date and time, you can use the command line interface or the configuration utility.

To view the system date and time by using the command line interface

At the command prompt, type:

```
show ns config
```

To view the system date and time by using the configuration utility

Navigate to System and select the System Information tab to view the system date.

Backing up and Restoring the NetScaler Appliance

Nov 21, 2016

You can back up the current state of a NetScaler appliance, and later use the backed up files to restore the appliance to the same state. You must use this feature before performing an upgrade or for precautionary reasons. A backup of a stable system enables you to restore the system to a stable point in the event that it becomes unstable.

Points to remember

- Sysid and Interfaces should be same.
- Network configuration should be supported on New Platform.
- New Platform build should is either same of backup file or higher version than it.

This document includes the following details:

Backing up a NetScaler Appliance

Depending on the type of data to be backed up and the frequency at which you will create a backup, you can take a basic backup or a full backup.

- **Basic backup.** Backs up only configuration files. You might want to perform this type of backup frequently, because the files it backs up change constantly. The files that are backed up are:

Directory	Sub-Directory or Files
/nsconfig/	• ns.conf • ZebOS.conf • rc.netscaler • snmpd.conf • nsbefore.sh • nsafter.sh • inetd.conf • ntp.conf • syslog.conf • newsyslog.conf • crontab • host.conf • hosts • ttys • sshd_config • httpd.conf • monitrc • rc.conf • ssh_config • localtime • issue • issue.net

Directory	Sub-Directory or Files
/var/	• download/* • log/wicmd.log • wi/tomcat/webapps/* • wi/tomcat/logs/* • wi/tomcat/conf/catalina/localhost/* • nslw.bin/etc/krb.conf • nslw.bin/etc/krb.keytab • netscaler/locdb/* • lib/likewise/db/* • vpn/bookmark/* • netscaler/crl • nstemplates/* • learnt_data/*
/netscaler/	• custom.html • vsr.htm

- **Full backup.** In addition to the files that are backed up by a basic backup, a full backup backs up some less frequently updated files. The files that are backed up when using the full backup option are:

Directory	Sub-Directory or Files
/nsconfig/	• ssl/* • license/* • fips/*
/var/	• netscaler/ssl/* • wi/java_home/jre/lib/security/cacerts/* • wi/java_home/lib/security/cacerts/*

The backup is stored as a compressed TAR file in the /var/ns_sys_backup/ directory. To avoid issues due to non-availability of disk space, you can store a maximum of 50 backup files in this directory. You can use the rm system backup command to delete existing backup files so that you can create more backups.

Note:

- While the backup operation is in progress, do not execute commands that affect the configuration.
- If a file that is required to be backed up is not available, the operation skips that file.

To backup the NetScaler by using the NetScaler command line interface

At the command prompt, do the following:

1. Save the NetScaler configurations.
   save ns config
2. Create the backup file.
   create system backup [<fileName>] -level <basic ¦ full> -comment <string>

Note: If the file name is not specified, the appliance creates a TAR file with the following naming convention: backup_<level>_<nsip_address>_<date-timestamp>.tgz.
Example: To backup the full appliance using the default naming convention for the backup file.
> create system backup -level full

3. Verify that the backup file was created.
   show system backup

   You can view properties of a specific backup file by using the fileName parameter.

To backup the NetScaler by using the configuration utility

Navigate to System > Backup and Restore, click Backup and then specify the details of the backup.

Restoring the NetScaler Appliance

When you restore the appliance from a backup file, the restore operation untars the backup file into the /var/ns_sys_backup/ directory. Once the untar operation is complete, the files are copied to their respective directories.

Attention: The restore operation does not succeed if the backup file is renamed or if the contents of the file are modified.

To restore the NetScaler from a local backup file by using the command line interface

Note: Citrix recommends backing up the current configuration before restoring a previous configuration. However, if you do not want the restore command to automatically create a backup of the current configuration, use the **–skipBackup** parameter.

At the command prompt, do the following:

1. Obtain a list of the backup files available on the appliance.
   show system backup

2. Restore the appliance by specifying one of the backup files.
   restore system backup <filename> [**-skipBackup**]

   Example: To restore by using a full backup of an appliance.
   > restore system backup backup_full_<nsip_address>_<date-timestamp>.tgz
3. Reboot the appliance.
   reboot

To restore the NetScaler from a local backup file by using the configuration utility

Navigate to System > Backup and Restore, right-click the backup file to be restored and click Restore.

To restore the NetScaler from a remote backup file by using the command line interface

Note: A remote backup file is any backup file that has been deleted from the NetScaler appliance.
Citrix recommends backing up the current configuration before restoring a previous configuration. However, if you do not want the restore command to automatically create a backup of the current configuration, use the –skipBackup parameter.

1. Copy the backup tar file from remote server to the local NetScaler appliance's /var/ns_sys_backup directory.

2. Add the backup metadata to the appliance's memory:

add system backup <backupFileName>

3. Restore the backed up configuration:

restore system backup <fileName> [–**skipBackup**]

Restarting or Shutting down the Appliance

Sep 16, 2014

The NetScaler appliance can be remotely restarted or shut down from the available user interfaces. When a standalone NetScaler appliance is restarted or shut down, the unsaved configurations (configurations performed since the last save ns config command was issued) are lost.

In a high availability setup, when the primary appliance is rebooted/shut down, the secondary appliance takes over and becomes the primary. The unsaved configurations from the old primary are available on the new primary appliance.

You can also restart the appliance by only rebooting the NetScaler software and not rebooting the underlying operating system. This is called a warm reboot. For example, when you add a new license or change the NetScaler IP address, you can warm reboot the NetScaler appliance for these changes to take place.

Note: Warm reboot can be performed only on nCore appliances.

To restart the NetScaler by using the command line interface

At the command prompt, type:

reboot [-warm]

To restart the NetScaler by using the configuration utility

1. In the configuration utility, click Reboot on the home page of the Configuration tab.
2. When prompted to reboot, select Save configuration to make sure that you do not lose any configurations.
   Note: You can perform a warm reboot by selecting Warm reboot.

To shut down the NetScaler by using the command line interface

At the command prompt, type:

- shutdown –p now: Shuts down the software and switches off the NetScaler. To restart NetScaler MPX, press the AC power switch. To Restart NetScaler VPX , restart the VPX instance.
- shutdown –h now: Shuts down the software and leaves the NetScaler switched on. Press any key to restart the NetScaler. This command does not switch off the NetScaler. Therefore, do not switch off the AC power or remove the AC power cables.

Note: The appliance cannot be shut down from the configuration utility.

Generating the NetScaler Technical Support Bundle

Oct 12, 2015

For help with analyzing and resolving any issues with a NetScaler appliance, you can generate a technical support bundle on the appliance and send the bundle to Citrix Technical Support. The NetScaler technical support bundle is a gzipped tar archive of system configuration data and statistics. It collects the following data from the NetScaler appliance on which you generate the bundle:

- **Configuration files**. All files in the /flash/nsconfig directory.
- **Newnslog files**. The currently running newnslog and some previous files. To minimize the archive file size, newnslog collection is restricted to 500 MB, 6 files, or 7 days, whichever occurs first. If older data is needed, it might require manual collection.
- **Log files**. Files in /var/log/messages*, /var/log/ns.log*, and other files under /var/log and /var/nslog.
- **Application core files**. Files created in the /var/core directory within the last week, if any.
- **Output of some CLI show commands**.
- **Output of some CLI stat commands**.
- **Output of BSD shell commands**.

You can use a single command to generate the technical support bundle and securely upload it to the Citrix Technical Support server. To upload, you must specify your My Citrix credentials. When you generate the bundle, you can specify the case or service request number that was allotted to you by Citrix Technical Support. If you have already generated a technical support bundle, you can upload the existing archive file to the Citrix Technical Support server by specifying the file name with the full path.

The technical support bundle is saved on the NetScaler appliance in an archive at the following location:

/var/tmp/support/support.tgz

The above path is a symlink to the most recent collector for easy access. The full filename varies, depending on the deployment topology, but generally follows a format similar to:

collector_<P/S>_<NS IP>_<DateTime>.tgz.

If your NetScaler appliance does not have direct Internet connectivity, you can use a proxy server to directly upload the technical support bundle to the Citrix Technical Support server. The basic format of the proxy string is:

proxy_IP:<proxy_port>

If the proxy server requires authentication, the format is:

username:password@proxsy_IP:<proxy_port>

> ## Note
>
> For NetScaler appliances in a high availability pair, you must generate the technical support bundle on each of the two nodes.
>
> For NetScaler appliances in a Cluster setup, you can generate the technical support bundle on each node individually, or you can generate smaller abbreviated archives for all nodes by using the cluster IP address.
>
> For NetScaler Admin Partitions, you must generate the technical support bundle from the default admin partition. To get the technical

support bundle for a specific partition, you must specify the name of the partition for which you want to generate the technical support bundle. If you do not specify the name of the partition, data is collected from all admin partitions.

To generate the NetScaler technical support bundle by using the command line interface

At the command prompt, type:

show techsupport [-**scope** <scope> <partitionName>] [-**upload** [-**proxy** <string>] [-**casenumber** <string>] [-**file** <string>] [-**description** <string>] [-**userName** <string> -**password**]]

Examples

Sr. No	Task	Command
1.	Generate and upload the technical support bundle to the Citrix Technical Support server.	show techsupport –upload –userName account1 –password xxxxxxx
2.	Generate and upload the technical support bundle to the Citrix Technical Support server through a proxy server.	show techsupport –upload –proxy 1.1.1.1:80 –userName account1 –password xxxxxxx
3.	Upload an existing technical support bundle to the Citrix Technical Support server.	show techsupport –upload -file /var/tmp/support/collector_P_10.102.29.160_9Sep2015_15_22.tar.gz –userName account1 –password xxxxxxx
4.	Generate small, abbreviated archives for all nodes in a Cluster setup. Execute this command by using the cluster IP address.	show techsupport –scope CLUSTER
5.	Generate a technical support bundle specific to an admin partition. Execute this command on the default admin partition.	show techsupport –scope PARTITION partition1

Allocating an Extra Management CPU

Jan 01, 2018

If you need better performance for configuration and monitoring of a NetScaler MPX appliance, you can allocate an extra management CPU from the appliance's packet engine pool. This feature is supported on NetScaler MPX models 25xxx, 22xxx, 14xxx, 115xx, 15xxx, and 26xxx. It affects the output of the stat system cpu and stat system commands.

> ### Note
>
> For NetScaler MPX 26xxx models with more than 20 cores, the mandatory extra management CPU feature is enabled by default.

You can use the NetScaler CLI, GUI, or NITRO API to allocate an extra management CPU. This section includes the following topics:

- Allocate or deallocate an extra management CPU by using the NetScaler CLI
- Allocate an extra management CPU by using the NetScaler GUI
- Configure an extra management CPU by using the NITRO API
- Statistics and Monitoring

Allocate or deallocate an extra management CPU by using the NetScaler CLI

At the command prompt, type one of the following commands:

- enable extramgmtcpu
- disable extramgmtcpu

> ### Note
>
> After you enable and disable this feature, the NetScaler appliance displays a warning to restart the appliance, for the changes to take effect.

To show the configured and effective state of an extra management CPU

At the command prompt, type:

command COPY

```
show extramgmtcpu
```

Example COPY

```
> show extramgmtcpu

ConfiguredState:  ENABLED EffectiveState:  ENABLED
```

> **Note**
>
> In this example, the show command is entered before restarting the appliance.

Parameter Descriptions of Commands Listed in the CLI Procedure

- **enable extramgmtcpu**

Enables and dedicates extra CPU for management from PE pool.

See also:

disable system extramgmtcpu

show system extramgmtcpu

- **disable extramgmtcpu**

Disables extra CPU for management and returns it to the PE pool.

See also:

enable system extramgmtcpu

show system extramgmtcpu

- **show extramgmtcpu**

Displays configured and effective states of the extra management CPU.

Configured and effective state are different if enable extramgmtcpu command has been entered but system is has not been restarted.

See also:

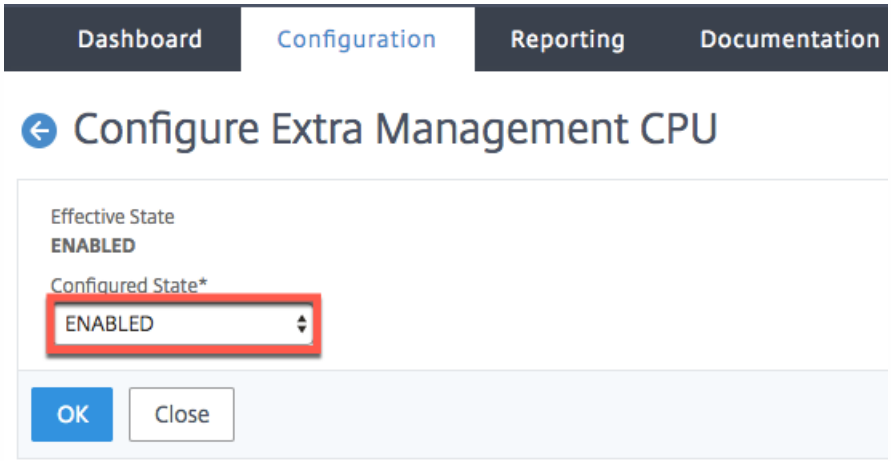
enable system extramgmtcpu

disable system extramgmtcpu

Allocate an extra management CPU by using the NetScaler GUI

To allocate an extra management CPU by using the NetScaler GUI, navigate to **System > Settings** and click **Configure**

Extra Management CPU. From the **Configured State** drop-down menu, select **Enabled** and then select **OK**.



To check CPU usage, go to **System** > **Settings** > **Dashboard**.

Configure an extra management CPU by using the NITRO API

Use the following NITRO methods and formats to enable, disable, and show an extra management CPU.

To enable an extra management CPU

HTTP Method: POST

URL: http://<NSIP>/nitro/v1/config/systemextramgmtcpu?action=enable

Payload: {"systemextramgmtcpu":{}}

Example COPY

```
curl -v -X POST -H "Content-Type: application/json" -u nsroot:nsroot http://10.102.201.92/nitro/v1/config/systemextramgmtcpu?action=en
```

To disable an extra management CPU

HTTP Method: POST

URL: http://<NSIP>/nitro/v1/config/systemextramgmtcpu?action=disable

Payload: {"systemextramgmtcpu":{}}

Example COPY

```
curl -v -X POST -H "Content-Type: application/json" -u nsroot:nsroot http://10.102.201.92/nitro/v1/config/systemextramgmtcpu?action=dis
```

To show an extra management CPU

HTTP Method: GET

URL: http://<NSIP>/nitro/v1/config/systemextramgmtcpu

Example COPY

```
curl -v -X GET -H "Content-Type: application/json" -u nsroot:nsroot http://10.102.201.92/nitro/v1/config/systemextramgmtcpu
```

Statistics and Monitoring

The following examples show the differences in the output of the stat system cpu and stat system commands before and after adding an extra management CPU.

1. stat system cpu

This command displays statistics of CPUs.

Here is a sample output before adding an extra management CPU on one of the supported models.

Example: Output Before Adding an Extra Management CPU COPY

```
> stat system cpu

CPU statistics

ID       Usage

8          1

7          1

11         2

1          1
```

```
6       1

9       1

3       1

5       1

4       1

10      1

2       1
```

Here is the output after adding an extra management CPU on the same MPX appliance.

Example: Output After Adding an Extra Management CPU COPY

```
> stat system cpu

CPU statistics

ID        Usage

9           1

7           1

5           1

8           1

11          2

10          1

6           1

4           1

3           1

2           1
```

2. stat system

This command displays CPU use. In the following example, the output before adding an extra management CPU on one of the supported models is:

Mgmt Additional-CPU usage (%) 0.00

Example: Output Before Adding an Extra Management CPU COPY

```
> stat system

NetScaler Executive View

System Information:

Up since        Wed Oct 11 11:17:54 2017

/flash Used (%)                    0

Packet CPU usage (%)               1.30

Management CPU usage (%)           4.00

Mgmt CPU0 usage (%)                4.00

Mgmt Additional-CPU  usage (%)     0.00

Memory usage (MB)                  2167

InUse Memory (%)                   5.76

/var Used (%)                      0
```

In the following example, the output after adding an extra management CPU on the same MPX appliance is:

```
Mgmt Additional-CPU  usage (%)     0.80
```

Example: Output After Adding an Extra Management CPU COPY

```
> stat system

NetScaler Executive View

System Information:

Up since        Wed Oct 11 11:55:56 2017

/flash Used (%)                    0

Packet CPU usage (%)               1.20

Management CPU usage (%)           5.70

Mgmt CPU0 usage (%)                10.60

Mgmt Additional-CPU  usage (%)     0.80

Memory usage (MB)                  1970

InUse Memory (%)                   5.75

/var Used (%)                      0
```

Authentication and Authorization

Mar 17, 2014

To configure NetScaler authentication and authorization, you must first define the users who have access to the NetScaler appliance, and then you can organize these users into groups. After configuring users and groups, you need to configure command policies to define types of access, and assign the policies to users and/or groups.

You must log on as an administrator to configure users, groups, and command policies. The default NetScaler administrator user name is *nsroot*. After logging on as the default administrator, you should change the password for the nsroot account. Once you have changed the password, no user can access the NetScaler appliance until you create an account for that user. If you forget the administrator password after changing it from the default, you can reset it to nsroot.

Note: Local users can authenticate to the NetScaler even if external authentication servers are configured. You can restrict this by disabling the localAuth parameter of the set system parameter command.

Configuring Users, User Groups, and Command Policies

Nov 02, 2017

You must define your users by configuring accounts for them. To simplify the management of user accounts, you can organize them into groups. You can create command policies, or use built-in command policies, to regulate user access to commands.

You can also customize the command-line prompt for a user. Prompts can be defined in a user's configuration, in a user-group configuration, and in the global system configuration settings. The prompt displayed for a given user is determined by the following order of precedence:

1. Display the prompt as defined in the user's configuration.
2. Display the prompt as defined in the group configuration for the user's group.
3. Display the prompt as defined in the system global configuration settings.

You can now specify a timeout value for inactive CLI sessions for a system user. If a user's CLI session is idle for a time that exceeds the timeout value, the NetScaler appliance terminates the connection. The timeout can be defined in a user's configuration, in a user-group configuration, and in the global system configuration settings. The timeout for inactive CLI sessions for a user is determined by the following order of precedence:

1. Timeout value as defined in the user's configuration.
2. Timeout value as defined in the group configuration for the user's group.
3. Timeout value as defined in the global system configuration settings.

A NetScaler root administrator can configure the maximum concurrent session limit for system users. By restricting the limit, you can reduce the number of open connections and improve server performance. As long as the CLI count is within the configured limit, concurrent users can log on the configuration utility any number of times. However, if the number of CLI sessions reaches the configured limit, users can no longer log on to the configuration utility. For example, if the number of concurrent session is configured to 20, concurrent users can log on to 19 CLI sessions. But if the user is logged on to the 20^{th} CLI session, any attempt to log on to the configuration utility, CLI or NITRO results in an error message ((ERROR: Connection limit to CFE exceeded).

Note: The default the number of concurrent sessions is configured to 20 and the maximum number of concurrent sessions is configured to 40.

This document includes the following details:

- Configuring User Accounts
- Configuring User Groups
- Configuring Command Policies

Configuring User Accounts

Updated: 2014-08-07

To configure user accounts, you simply specify user names and passwords. You can change passwords and remove user accounts at any time.

To create a user account by using the command line interface

At the command prompt, type the following commands to create a user account and verify the configuration:

- add system user <username> [-externalAuth (ENABLED | DISABLED)] [-promptString <string>] [-timeout <secs>] [-logging (ENABLED | DISABLED)] [-maxsession <positive_integer>]
- show system user <userName>

Where Logging option is for external users to collect log data externally using weblogging or audit logging mechanism. If enabled, the auditing client authenticates itself with NetScaler to collect logs through this user account.

Example

> add system user johnd -promptString user-%u-at-%T

Enter password:

Confirm password:

> show system user johnd

user name: john

Timeout:900 Timeout Inherited From: Global

External Authentication: ENABLED

Logging: DISABLED

Maximum Client Sessions: 20

To configure a user account by using the configuration utility

Navigate to System > User Administration > Users, and create the user.

Configuring User Groups

Updated: 2014-08-07

After configuring a user group, you can easily grant the same access rights to everyone in the group. To configure a group, you create the group and bind users to the group. You can bind each user account to more than one group. Binding user accounts to multiple groups might allow more flexibility when applying command policies.

To create a user group by using the command line interface

At the command prompt, type the following commands to create a user group and verify the configuration:

- add system group <groupName> [-promptString <string>] [-timeout <secs>]
- show system group <groupName>

Example

> add system group Managers -promptString Group-Managers-at-%h

To bind a user to a group by using the command line interface

At the command prompt, type the following commands to bind a user account to a group and verify the configuration:

- bind system group <groupName> -userName <userName>
- show system group <groupName>

Example

> bind system group Managers -userName user1

To configure a user group by using the configuration utility

Navigate to System > User Administration > Groups, and create the user group.

Note: To add members to the group, in the Members section, click Add. Select users from the Available list and add them to the Configured list.

Configuring Command Policies

Command policies regulate which commands, command groups, virtual servers, and other entities that users and user groups are permitted to use.

The appliance provides a set of built-in command policies, and you can configure custom policies. To apply the policies, you bind them to users and/or groups.

Here are the key points to keep in mind when defining and applying command policies.

- You cannot create global command policies. Command policies must be bound directly to the users and groups on the appliance.
- Users or groups with no associated command policies are subject to the default (DENY-ALL) command policy, and are therefore unable to execute any configuration commands until the proper command policies are bound to their accounts.
- All users inherit the policies of the groups to which they belong.
- You must assign a priority to a command policy when you bind it to a user account or group account. This enables the appliance to determine which policy has priority when two or more conflicting policies apply to the same user or group.
- The following commands are available by default to any user and are unaffected by any command you specify:
  help, show cli attribute, set cli prompt, clear cli prompt, show cli prompt, alias, unalias, history, quit, exit,whoami, config, set cli mode, unset cli mode, and show cli mode.

Built-in Command Policies

Updated: 2015-06-15

The following table describes the built-in policies.

Table 1. Built-in Command Policies

Policy name	Allows
read-only	Read-only access to all show commands except show ns runningConfig, show ns ns.conf, and the show commands for the NetScaler command group.
operator	Read-only access and access to commands to enable and disable services and servers.
network	Full access, except to the set and unset SSL commands, show ns ns.conf, show ns runningConfig, and show gslb runningConfig commands.
sysadmin	[Included in NetScaler 11.0 and later] A sysadmin is lower than a superuser is terms of access allowed on the appliance. A sysadmin user can perform all NetScaler operations with the following exceptions: no access to the NetScaler shell, cannot perform user configurations, cannot perform partition configurations, and some other configurations as stated in the sysadmin command policy.
superuser	Full access. Same privileges as the nsroot user.

Creating Custom Command Policies

Updated: 2015-06-15

Regular expression support is offered for users with the resources to maintain more customized expressions, and for those deployments that require the flexibility that regular expressions offer. For most users, the built-in command policies are sufficient. Users who need additional levels of control but are unfamiliar with regular expressions might want to use only simple expressions, such as those in the examples provided in this section, to maintain policy readability.

When you use a regular expression to create a command policy, keep the following in mind.

- When you use regular expressions to define commands that will be affected by a command policy, you must enclose the commands in double quotation marks. For example, to create a command policy that includes all commands that begin with show, type the following:
  "^show .*$"

  To create a command policy that includes all commands that begin with rm, type the following:

  "^rm .*$"
- Regular expressions used in command policies are not case sensitive.

The following table lists examples of regular expressions:

Table 2. Examples of Regular Expressions for Command Policies

Command specification	Matches these commands
"^rm\s+.*$"	All remove actions, because all remove actions begin with the rm string, followed by a space and additional parameters such as command groups, command object types, and arguments.
"^show\s+.*$"	All show commands, because all show actions begin with the show string, followed by a space and additional parameters such as command groups, command object types, and arguments.
"^shell$"	The shell command alone, but not combined with any additional parameters such as command groups, command object types, and arguments.
"^add\s+vserver\s+.*$"	All create virtual server actions, which consist of the add virtual server command followed by a space and additional parameters such as command groups, command object types, and arguments.
"^add\s+(lb\s+vserver)\s+.*"	All create lb virtual server actions, which consist of the add lb virtual server command followed by a space and additional parameters such as command groups, command object types, and arguments.

The following table shows the command specifications for each of the built-in command policies.

Table 3. Expressions Used in the Built-in Command Policies

Policy name	Command specification regular expression
read-only	(^man.*)|(^show\s+(?!system)(?!configstatus)(?!ns ns\.conf)(?!ns savedconfig)(?!ns runningConfig)(?!gslb runningConfig)(?!audit messages)(?!techsupport).*)|(^stat.*)
operator	(^man.*)|(^show\s+(?!system)(?!configstatus)(?!ns ns\.conf)(?!ns savedconfig)(?!ns runningConfig)(?!gslb runningConfig)(?!audit messages)(?!techsupport).*)|(^stat.*)|(^(enable|disable) (server|service).*)
network	^(?!clear ns config.*)(?!scp.*)(?!set ssl fips)(?!reset ssl fips)(?!diff ns config)(?!shell)(?!reboot)(?!batch)\S+\s+(?!system)(?!configstatus)(?!ns ns\.conf)(?!ns savedconfig)(?!ns runningConfig)(?!gslb runningConfig)(?!techsupport).*
sysadmin	[From NetScaler 11 onwards] ^(?!shell)(?!sftp)(?!scp)(?!batch)(?!source)(?!.*superuser)(?!.*nsroot)(?!show\s+system\s+(user|cmdPolicy))(?!(set|add|rm|create|export|kill)\s+system)(?!(unbind|bind)\s+system\s+(user|group))(?!diff\s+ns\s+config)(?!\S+\s+ns\s+partition).*
superuser	.*

To create a command policy by using the command line interface

At the command prompt, type the following commands to create a command policy and verify the configuration:

- add system cmdPolicy <policyname> <action> <cmdspec>
- show system cmdPolicy <policyName>

Example

> add system cmdPolicy read_all ALLOW (^show\s+(!system)(!ns ns.conf)(!ns runningConfig).*)|(^stat.*)

To configure a command policy by using the configuration utility

Navigate to System > User Administration > Command Policies, and create the command policy.

Binding Command Policies to Users and Groups

Updated: 2014-08-07

Once you have defined your command policies, you must bind them to the appropriate user accounts and groups. When you bind a policy, you must assign it a priority so that the appliance can determine which command policy to follow when two or more applicable command policies are in conflict.

Command policies are evaluated in the following order:

- Command policies bound directly to users and the corresponding groups are evaluated according to priority number. A command policy with a lower priority number is evaluated before one with a higher priority number. Therefore, any privileges the lower-numbered command policy explicitly grants or denies are not overridden by a higher-numbered command policy.
- When two command policies, one bound to a user account and other to a group, have the same priority number, the command policy bound directly to the user account is evaluated first.

To bind command policies to a user by using the command line interface

At the command prompt, type the following commands to bind a command policy to a user and verify the configuration:

- bind system user <userName> -policyName <policyName> <priority>
- show system user <userName>

Example

> bind system user user1 -policyName read_all 1

To bind command policies to a user by using the configuration utility

Navigate to System > User Administration > Users, select the user and bind command policies.

Optionally, you can modify the default priority to ensure that the policy is evaluated in the proper order.

To bind command policies to a group by using the command line interface

At the command prompt, type the following commands to bind a command policy to a user group and verify the configuration:

- bind system group <groupName> -policyName <policyName> <priority>
- show system group <groupName>

Example

> bind system group Managers -policyName read_all 1

To bind command policies to a group by using the configuration utility

Navigate to System > User Administration > Groups, select the group and bind command policies.

Optionally, you can modify the default priority to ensure that the policy is evaluated in the proper order.

Resetting the Default Administrator (nsroot) Password

Nov 24, 2014

The nsroot account provides complete access to all features of the appliance. Therefore, to preserve security, the nsroot account should be used only when necessary, and only individuals whose duties require full access should know the password for the nsroot account. Frequently changing the nsroot password is advisable. If you lose the password, you can reset it to the default and then change it.

To reset the nsroot password, you must boot the appliance into single user mode, mount the file systems in read/write mode, and remove the set NetScaler user nsroot entry from the ns.conf file. You can then reboot, log on with the default password, and choose a new password.

To reset the nsroot password

1. Connect a computer to the console port of the NetScaler ADC and log on.
   Note: You cannot log on by using SSH to perform this procedure; you must connect directly to the appliance.
2. Reboot the NetScaler ADC.
3. Press CTRL+C when the following message appears:
   Press [Ctrl-C] for command prompt, or any other key to boot immediately.

   Booting [kernel] in # seconds.
4. Run the following command to start the NetScaler in a single user mode:
   boot -s

   Note: If boot -s does not work, then try reboot -- -s and appliance will reboot in single user mode.
   After the appliance boots, it displays the following message:

   Enter full path name of shell or RETURN for /bin/sh:
5. Press ENTER key to display the # prompt, and type the following commands to mount the file systems:
   1. Run the following command to check the disk consistency:
      fsck /dev/ad0s1a

      Note: Your flash drive will have a specific device name depending on your NetScaler; hence, you have to replace ad0s1a in the preceding command with the appropriate device name.
   2. Run the following command to display the mounted partitions:
      df

      If the flash partition is not listed, you need to mount it manually.

   3. Run the following command to mount the flash drive:
      mount /dev/ad0s1a /flash
6. Run the following command to change to the nsconfig directory:
   cd /flash/nsconfig
7. Run the following commands to rewrite the ns.conf file and remove the set of system commands defaulting to the nsroot user:
   1. Run the following command to create a new configuration file that does not have commands defaulting to the

nsroot user:
grep –v “set system user nsroot” ns.conf > new.conf

2. Run the following command to make a backup of the existing configuration file:
   mv ns.conf old.ns.conf

3. Run the following command to rename the new.conf file to ns.conf:
   mv new.conf ns.conf

8. Run the following command to reboot the NetScaler:
   reboot

9. Log on using the default nsroot user credentials.
10. Run the following command to reset the nsroot user password:
    set system user nsroot <New_Password>

    Note: To use the "?" character in a password string, precede this character with the “\” character.

    For example, yourexamplepasswd\? is set for the nsroot account after you perform the following operation:

    > set system user nsroot yourexamplepasswd\?

Example of a User Scenario

Sep 06, 2013

The following example shows how to create a complete set of user accounts, groups, and command policies and bind each policy to the appropriate groups and users. The company, Example Manufacturing, Inc., has three users who can access the NetScaler appliance:

- **John Doe.** The IT manager. John needs to be able to see all parts of the NetScaler configuration but does not need to modify anything.
- **Maria Ramiez.** The lead IT administrator. Maria needs to be able to see and modify all parts of the NetScaler configuration except for NetScaler commands (which local policy dictates must be performed while logged on as nsroot).
- **Michael Baldrock.** The IT administrator in charge of load balancing. Michael needs to be able to see all parts of the NetScaler configuration, but needs to modify only the load balancing functions.

The following table shows the breakdown of network information, user account names, group names, and command policies for the sample company.

Table 1. Sample Values for Creating Entities

Field	Value	Note
NetScaler host name	ns01.example.net	N/A
User accounts	johnd, mariar, and michaelb	John Doe, IT manager, Maria Ramirez, IT administrator and Michael Baldrock, IT administrator.
Groups	Managers and SysOps	All managers and all IT administrators.
Command Policies	read_all, modify_lb, and modify_all	Allow complete read-only access, Allow modify access to load balancing, and Allow complete modify access.

The following description walks you through the process of creating a complete set of user accounts, groups, and command policies on the NetScaler appliance named ns01.example.net.

The description includes procedures for binding the appropriate user accounts and groups to one another, and binding appropriate command policies to the user accounts and groups.

This example illustrates how you can use prioritization to grant precise access and privileges to each user in the IT department.

The example assumes that initial installation and configuration have already been performed on the NetScaler.

Configuration steps

1. Use the procedure described in "Configuring User Accounts" to create user accounts **johnd**, **mariar**, and **michaelb**.
2. Use the procedure described in "Configuring User Groups" to create user groups **Managers** and **SysOps**, and then bind the users **mariar** and **michaelb** to the **SysOps** group and the user **johnd** to the **Managers** group.

3. Use the procedure described in "Creating Custom Command Policies" to create the following command policies:
   - **read_all** with action **Allow** and command spec "(^show\s+(?!system)(?!ns ns.conf)(?!ns runningConfig).*)|(^stat.*)"
   - **modify_lb** with action as **Allow** and the command spec "^set\s+lb\s+.*$"
   - **modify_all** with action as **Allow** and the command spec **"^\S+\s+(?!system).*"**
4. Use the procedure described in "Binding Command Policies to Users and Groups" to bind the **read_all** command policy to the **SysOps** group, with priority value **1**.
5. Use the procedure described in "Binding Command Policies to Users and Groups" to bind the **modify_lb** command policy to user **michaelb**, with priority value **5**.

The configuration you just created results in the following:

- John Doe, the IT manager, has read-only access to the entire NetScaler configuration, but he cannot make modifications.
- Maria Ramirez, the IT lead, has near-complete access to all areas of the NetScaler configuration, having to log on only to perform NetScaler-level commands.
- Michael Baldrock, the IT administrator responsible for load balancing, has read-only access to the NetScaler configuration, and can modify the configuration options for load balancing.

The set of command policies that applies to a specific user is a combination of command policies applied directly to the user's account and command policies applied to the group(s) of which the user is a member.

Each time a user enters a command, the operating system searches the command policies for that user until it finds a policy with an ALLOW or DENY action that matches the command. When it finds a match, the operating system stops its command policy search and allows or denies access to the command.

If the operating system finds no matching command policy, it denies the user access to the command, in accordance with the NetScaler appliance's default deny policy.

Note: When placing a user into multiple groups, take care not to cause unintended user command restrictions or privileges. To avoid these conflicts, when organizing your users in groups, bear in mind the NetScaler command policy search procedure and policy ordering rules.

Configuring External User Authentication

Jun 20, 2017

Authentication in a NetScaler appliance can be local or external. For authenticating external users, the appliance uses an external authentication server such as LDAP, RADIUS and TACACS+. In order to authenticate an external user and grant user access into the appliance, you must use an authentication policy. The NetScaler system authentication supports two types of authentication polices – Classic authentication policy and Advanced authentication policy. You can configure either a classic or advanced policy depending on your authentication need. Classic authentication policies use classic policy expressions and Advanced authentication policies use NetScaler advanced policy expressions. Advanced authentication policies are used for system user management in a partitioned NetScaler appliance.

Once you create an authentication policy, you must bind it to system global entity. You can configure an external authentication server (for example, TACACS) by binding a single authentication policy to the system global entity. Or, you can configure a cascade of authentication servers by binding multiple policies to the system global entity.

This document includes the following details:

- Configuring LDAP Authentication
- Configuring RADIUS Authentication
- Configuring TACACS+ Authentication
- Binding the Authentication Policies to the System Global Entity

Configuring LDAP Authentication

Updated: 2014-12-29

You can configure the NetScaler appliance to authenticate user access with one or more LDAP servers. LDAP authorization requires identical group names in Active Directory, on the LDAP server, and on the appliance. The characters and case must also be the same.

By default, LDAP authentication is secured by using SSL/TLS protocol. There are two types of secure LDAP connections. In the first type, the LDAP server accepts the SSL/TLS connection on a port separate from the port used to accept clear LDAP connections. After users establish the SSL/TLS connection, LDAP traffic can be sent over the connection. The second type allows both unsecure and secure LDAP connections and is handled by a single port on the server. In this scenario, to create a secure connection, the client first establishes a clear LDAP connection. Then the LDAP command StartTLS is sent to the server over the connection. If the LDAP server supports StartTLS, the connection is converted to a secure LDAP connection by using TLS.

The port numbers for LDAP connections are:

- 389 for unsecured LDAP connections
- 636 for secure LDAP connections
- 3268 for Microsoft unsecure LDAP connections
- 3269 for Microsoft secure LDAP connections

LDAP connections that use the StartTLS command use port number 389. If port numbers 389 or 3268 are configured on the appliance, it tries to use StartTLS to make the connection. If any other port number is used, connection attempts use SSL/TLS. If StartTLS or SSL/TLS cannot be used, the connection fails.

When configuring the LDAP server, the case of the alphabetic characters must match that on the server and on the appliance. If the root directory of the LDAP server is specified, all of the subdirectories are also searched to find the user attribute. In large directories, this can affect performance. For this reason, Citrix recommends that you use a specific organizational unit (OU).

The following table lists examples of user attribute fields for LDAP servers.

Table 1. User Attribute Fields for LDAP Servers

LDAP server	User attribute	Case sensitive?
Microsoft Active Directory	Server sAMAccountName	No
Novell eDirectory	cn	Yes
IBM Directory Server	uid	Yes
Lotus Domino	CN	Yes
Sun ONE directory (formerly iPlanet)	uid or cn	Yes

The following table lists examples of the base distinguished name (DN).

Table 2. Examples of Base Distinguished Name

LDAP server	Base DN
Microsoft Active Directory	DC=citrix, DC=local
Novell eDirectory	dc=citrix, dc=net
IBM Directory Server	cn=users
Lotus Domino	OU=City, O=Citrix, C=US

LDAP server	Base DN
Sun ONE directory (formerly iPlanet)	ou=People, dc=citrix, dc=com

The following table lists examples of the bind distinguished name (DN).

Table 3. Examples of Bind Distinguished Name

LDAP server	Bind DN
Microsoft Active Directory	CN=Administrator, CN=Users, DC=citrix, DC=local
Novell eDirectory	cn=admin, dc=citrix, dc=net
IBM Directory Server	LDAP_dn
Lotus Domino	CN=Notes Administrator, O=Citrix, C=US
Sun ONE directory (formerly iPlanet)	uid=admin, ou=Administrators, ou=TopologyManagement, o=NetscapeRoot

Configure LDAP authentication by using the command line interface

To configure LDAP classic policy

At the command prompt, do the following:

1. Create an LDAP action.
   add authentication ldapAction <name> {-serverIP <ip_addr|ipv6_addr|*> | {-serverName <string>}} >] [-authTimeout <positive_integer>] [-ldapBase <string>] [-ldapBindDn <string>] {-ldapBindDnPassword } [-ldapLoginName <string>] [-groupAttrName <string>] [-subAttributeName <string>]

   Example:
   add authentication ldapAction ldap_act -serverIP <IP> -authTimeout 30 -ldapBase "CN=xxxxx,DC=xxxx,DC=xxx" -ldapBindDn "CN=xxxxx,CN=xxxxx,DC=xxxx,DC=xxx" -ldapBindDnPassword abcd -l

2. Create an LDAP policy.
   Creating an LDAP Classic authentication policy:

   add authentication ldapPolicy <name> <rule> [<reqAction>]

   Example:

   add authentication ldappolicy ldap_pol_classic ns_true ldap_act

   Creating an LDAP Advanced authentication policy:

   add authentication ldapPolicy <name> <rule> [<reqAction>]

   Example:

   add authentication policy ldap_pol_advance -rule true -action ldap_act

3. Bind the LDAP policy to the following bind points at which the policy will be evaluated.
   - **System Global**: bind system global <policyName> [-priority <positive_integer>]
   - **VPN Global**: bind vpn global <policyName> [-priority <positive_integer>]
   - **Authentication Server**: bind authentication vserver <name> [-policy <string> [-priority <positive_integer>]
   - **VPN Server**: bind vpn vserver <name> [-policy <string> [-priority <positive_integer>]

To configure LDAP classic policy

At the command prompt, type:

add authentication Policy <name> -rule <expression> -action <string>

Example:

add authentication policy ldap_pol_classic -rule true -action ldap_act

To configure LDAP authentication by using the configuration utility

Navigate to System > Authentication > LDAP, and create the LDAP authentication policy.

Determining attributes in the LDAP directory

If you need help determining your LDAP directory attributes, you can easily look them up with the free LDAP browser from Softerra.

You can download the LDAP browser from the Softerra LDAP Administrator Web site at http://www.ldapbrowser.com. After the browser is installed, set the following attributes:

- The host name or IP address of your LDAP server.
- The port of your LDAP server. The default is 389.

- The base DN field can be left blank.
- The information provided by the LDAP browser can help you determine the base DN needed for the Authentication tab.
- The Anonymous Bind check determines whether the LDAP server requires user credentials for the browser to connect to it. If the LDAP server requires credentials, leave the check box cleared.

After completing the settings, the LDAP browser displays the profile name in the left pane and connects to the LDAP server.

Configuring RADIUS Authentication

Updated: 2014-08-08

You can configure the NetScaler appliance to authenticate user access with one or more RADIUS servers. If you are using RSA SecurID, SafeWord, or Gemalto Protiva products, use a RADIUS server.

Your configuration might require using a network access server IP address (NAS IP) or a network access server identifier (NAS ID). When configuring the appliance to use a RADIUS authentication server, use the following guidelines:
- If you enable use of the NAS IP, the appliance sends its configured IP address to the RADIUS server, rather than the source IP address used in establishing the RADIUS connection.
- If you configure the NAS ID, the appliance sends the identifier to the RADIUS server. If you do not configure the NAS ID, the appliance sends its host name to the RADIUS server.
- When the NAS IP is enabled, the appliance ignores any NAS ID that was configured by using the NAS IP to communicate with the RADIUS server.

To configure RADIUS authentication by using the configuration utility

Navigate to System > Authentication > Radius, and create the RADIUS authentication policy.

Choosing RADIUS authentication protocols

The NetScaler appliance supports implementations of RADIUS that are configured to use any of several protocols for user authentication, including:
- Password Authentication Protocol
- Challenge-Handshake Authentication Protocol (CHAP)
- Microsoft Challenge-Handshake Authentication Protocol (MS-CHAP Version 1 and Version 2)

If your deployment of the appliance is configured to use RADIUS authentication and your RADIUS server is configured to use Password Authentication Protocol, you can strengthen user authentication by assigning a strong shared secret to the RADIUS server. Strong RADIUS shared secrets consist of random sequences of uppercase and lowercase letters, numbers, and punctuation, and are at least 22 characters long. If possible, use a random character generation program to determine RADIUS shared secrets.

To further protect RADIUS traffic, assign a different shared secret to each appliance or virtual server. When you define clients on the RADIUS server, you can also assign a separate shared secret to each client. If you do this, you must configure separately each policy that uses RADIUS authentication.

Shared secrets are configured on the appliance when a RADIUS policy is created.

Configuring IP address extraction

You can configure the appliance to extract the IP address from a RADIUS server. When a user authenticates with the RADIUS server, the server returns a framed IP address that is assigned to the user. The following are attributes for IP address extraction:
- Allows a remote RADIUS server to supply an IP address from the internal network for a user logged on to the appliance.
- Allows configuration for any RADIUS attribute using the type ipaddress, including those that are vendor encoded.

When configuring the RADIUS server for IP address extraction, you configure the vendor identifier and the attribute type.

The vendor identifier enables the RADIUS server to assign an IP address to the client from a pool of IP addresses that are configured on the RADIUS server. The vendor ID and attributes are used to make the association between the RADIUS client and the RADIUS server. The vendor ID is the attribute in the RADIUS response that provides the IP address of the internal network. A value of zero indicates that the attribute is not vendor encoded. The attribute type is the remote IP address attribute in a RADIUS response. The minimum value is one and the maximum value is 255.

A common configuration is to extract the RADIUS attribute *framed IP address*. The vendor ID is set to zero or is not specified. The attribute type is set to eight.

To configure IP address extraction by using the configuration utility

1. Navigate to System > Authentication > Radius, and select a policy.
2. Modify the server parameters and set relevant values in Group Vendor Identifier and Group Attribute Type fields.

Configuring TACACS+ Authentication

Updated: 2014-08-07

You can configure a TACACS+ server for authentication. Similar to RADIUS authentication, TACACS+ uses a secret key, an IP address, and the port number. The default port number is 49. To configure the appliance to use a TACACS+ server, provide the server IP address and the TACACS+ secret. The port needs to be specified only when the server port number in use is something other than the default port number of 49.

To configure TACACS+ authentication by using the configuration utility

Navigate to System > Authentication > TACACS, and create the TACACS authentication policy.
After the TACACS+ server settings are configured on the appliance, bind the policy to the system global entity. For more information about binding authentication policies globally, see "Binding the Authentication Policies to the System Global Entity."

Binding Authentication Policies to the System Global Entity

Updated: 2014-12-30

When the authentication policies are configured, bind the policies to the system global entity.

To bind a classic authentication policy to system global using the command line interface

At the command line prompt, do the following:

bind system global <policyName> [-priority <positive_integer>]

Example:
bind system global ldap_pol_classic -priority 10

To bind advanced authentication policy to system global using the command line interface

At the command line prompt, do the following:

bind system global <policyName> [-priority <positive_integer>]

Example:

bind system global ldap_pol_advanced -priority 10

To bind an authentication policy to system global using the configuration utility

1. Navigate to System > Authentication, and select the authentication type.
2. On the Policies tab, click Global Bindings and bind the authentication policies.

TCP Configurations

Nov 01, 2017

TCP configurations for a NetScaler appliance can be specified in an entity called a TCP profile, which is a collection of TCP settings. The TCP profile can then be associated with services or virtual servers that want to use these TCP configurations.

A default TCP profile can be configured to set the TCP configurations that will be applied by default, globally to all services and virtual servers.

Note: When a TCP parameter has different values for service, virtual server, and globally, the value of the most-specific entity (the service) is given the highest precedence.
The NetScaler appliance also provides other approaches for configuring TCP. Read on for more information.

The NetScaler appliance supports the following TCP capabilities:

- Defending TCP against spoofing attacks. The NetScaler implementation of window attenuation is RFC 4953 compliant.
- Explicit Congestion Notification (ECN), which sends notification of the network congestion status to the sender of the data and takes corrective measures for data congestion or data corruption. The NetScaler implementation of ECN is RFC 3168 compliant.
- Round Trip Time Measurement (RTTM) using the TimeStamp option. For the TimeStamp option to work, at least one side of the connection (client or server) must support it. The NetScaler implementation of TimeStamp option is RFC 1323 compliant.
- Detection of spurious retransmissions can be done using TCP duplicate selective acknowledgment (D-SACK) and forward RTO-Recovery (F-RTO). In case of spurious retransmissions, the congestion control configurations are reverted to their original state. The NetScaler implementation of D-SACK is RFC 2883 compliant, and F-RTO is RFC 5682 compliant.
- Congestion control using New-Reno, BIC, CUBIC,, Nile and TCP Westwood algorithms.
- Window scaling to increase the TCP receive window size beyond its maximum value of 65,535 bytes.
  Note: Before configuring window scaling, make sure that:
  - You do not set a high value for the scale factor, because this could have adverse effects on the appliance and the network.
  - You do not configure window scaling unless you clearly know why you want to change the window size.
  - Both hosts in the TCP connection send a window scale option during connection establishment. If only one side of a connection sets this option, window scaling is not used for the connection.
  - Each connection for same session is an independent window scaling session. For example, when a client's request and the server's response flow through the appliance, it is possible to have window scaling between the client and the appliance without window scaling between the appliance and the server.
- TCP maximum congestion window size that is user configurable. The default value is 8190 bytes.
- Selective acknowledgment (SACK), using which the data receiver (either a NetScaler appliance or a client) notifies the sender about all the segments that have been received successfully.
- Forward acknowledgment (FACK) avoids TCP congestion by explicitly measuring the total number of data bytes outstanding in the network, and helping the sender (either a NetScaler ADC or a client) control the amount of data injected into the network during retransmission timeouts.
- TCP connection multiplexing enables reuse of existing TCP connections. The NetScaler appliance stores established TCP connections to the reuse pool. Whenever a client request is received, appliance checks for an available connection in the reuse pool and serves the new client if the connection is available. If it is unavailable, the appliance creates a new connection for the client request and stores the connection to the reuse pool.
  NetScaler supports connection multiplexing for HTTP, SSL, and DataStream connection types.

- Dynamic receive buffering allows the receive buffer to be adjusted dynamically based on memory and network conditions.
- MPTCP connections between client and NetScaler. MPTCP connections are not supported between NetScaler and the backend server.
  The NetScaler implementation of MPTCP is RFC 6824 compliant.

  Note:
  - To establish an MPTCP connection, both the client and the Netscaler appliance must support the same MPTCP version. If you use the NetScaler appliance as an MPTCP gateway for your servers, the servers do not have to support MPTCP. When the client starts a new MPTCP connection, the appliance identifies the client's MPTPC version from the MP_CAPABALE option in the SYN packet. If the client's version is higher than the one supported on the appliance, the appliance indicates its highest version in the MP_CAPABALE option of the SYN-ACK packet. The client then falls back to a lower version and sends the version number in the MP_CAPABALE option of the ACK packet. If that version is supportable, the appliance continues the MPTCP connection. Otherwise, the appliance falls back to a regular TCP.
  - The NetScaler appliance does not initiate subflows (MP_JOIN's). The appliance expects the client to initiate subflows.
- TCP keep-alive to monitor the TCP connections to verify if the peers are up.
- Extracting the TCP/IP path overlay option and inserting client-IP HTTP header. Extracting TCP/IP path overlay and inserting client-IP HTTP header. Data transport through overlay networks often uses connection termination or Network Address Translation (NAT), in which the IP address of the source client is lost. To avoid this, the Netscaler appliance extracts the TCP/IP path overlay option and inserts the source client's IP address into the HTTP header. With the IP address in the header, the web server can identify the source client that made the connection. The extracted data is valid for lifetime of the TCP connection and therefore, this prevents the next hop host from having to interpret the option again. This option is applicable only for web services that have the client-IP insertion option enabled. For more information, see Client Insertion on backend topic.

Additionally, NetScaler provides configuration support for the following:

- TCP segmentation offload.
- Synchronizing cookie for TCP handshake with clients. Disabling this capability prevents SYN attack protection on the NetScaler appliance.
- Learning MSS to enable MSS learning for all the virtual servers configured on the appliance.

This document includes the following details:
- Setting Global TCP Parameters
- Setting Service or Virtual Server Specific TCP Parameters
- Built-in TCP Profiles
- Sample TCP Configurations

Setting Global TCP Parameters

The NetScaler appliance allows you to specify values for TCP parameters that are applicable to all NetScaler services and virtual servers. This can be done using:

- Default TCP profile
- Global TCP command
- TCP buffering feature

Note: The recvBuffSize parameter of the set ns tcpParam command is deprecated from release 9.2 onwards. In later releases, set the buffer size by using the bufferSize parameter of the set ns tcpProfile command. If you upgrade to a

release where the recvBuffSize parameter is deprecated, the bufferSize parameter is set to its default value.

Default TCP profile

A TCP profile, named as nstcp_default_profile, is used to specify TCP configurations that will used if no TCP configurations are provided at the service or virtual server level.

Note:

- Not all TCP parameters can be configured through the default TCP profile. Some settings have to be performed by using the global TCP command (see section below).
- The default profile does not have to be explicitly bound to a service or virtual server.

To configure the default TCP profile

- Using the command line interface, at the command prompt enter:

  set ns tcpProfile nstcp_default_profile ...

- On the configuration utility, navigate to System > Profiles, click TCP Profiles and update nstcp_default_profile.

Global TCP command

Another approach you can use to configure global TCP parameters is the global TCP command. In addition to some unique parameters, this command duplicates some parameters that can be set by using a TCP profile. Any update made to these duplicate parameters is reflected in the corresponding parameter in the default TCP profile.

For example, if the SACK parameter is updated using this approach, the value is reflected in the SACK parameter of the default TCP profile (nstcp_default_profile).

Note: Citrix recommends that you use this approach only for TCP parameters that are not available in the default TCP profile.

To configure the global TCP command

- Using the command line interface, at the command prompt enter:

  set ns tcpParam ...

- On the configuration utility, navigate to System > Settings, click Change TCP parameters and update the required TCP parameters.

TCP buffering feature

NetScaler provides a feature called TCP buffering that you can use to specify the TCP buffer size. The feature can be enabled globally or at service level.

Note: The buffer size can also be configured in the default TCP profile. If the buffer size has different values in the TCP buffering feature and the default TCP profile, the greater value is applied.

To configure the TCP buffering feature globally

- At the command prompt enter:

  enable ns mode TCPB

set ns tcpbufParam -size <positiveInteger> -memLimit <positiveInteger>

- On the configuration utility, navigate to System > Settings, click Configure Modes and select TCP Buffering.
  And, navigate to System > Settings, click Change TCP parameters and specify the values for Buffer size and Memory usage limit.

Setting Service or Virtual Server Specific TCP Parameters

Using TCP profiles, you can specify TCP parameters for services and virtual servers. You must define a TCP profile (or use a built-in TCP profile) and associate the profile with the appropriate service and virtual server.

Note:

- You can also modify the TCP parameters of default profiles as per your requirements. For more information on built-in TCP profiles, see Built-in TCP Profiles.
- You can specify the TCP buffer size at service level using the parameters specified by the TCP buffering feature.

To specify service or virtual server level TCP configurations by using the command line interface

At the command prompt, perform the following:

1. Configure the TCP profile.
   set ns tcpProfile <profile-name>...
2. Bind the TCP profile to the service or virtual server.
   To bind the TCP profile to the service:

   set service <name> ....

   Example:
   > set service service1 -tcpProfileName profile1
   To bind the TCP profile to the virtual server:

   set lb vserver <name> ....

   Example:
   > set lb vserver lbvserver1 -tcpProfileName profile1

To specify service or virtual server level TCP configurations by using the configuration utility

At the configuration utility, perform the following:

1. Configure the TCP profile.
   Navigate to System > Profiles > TCP Profiles, and create the TCP profile.
2. Bind the TCP profile to the service or virtual server.
   Navigate to Traffic Management > Load Balancing > Services/Virtual Servers, and create the TCP profile, which should be bound to the service or virtual server.

Built-in TCP Profiles

For convenience of configuration, the NetScaler provides some built-in TCP profiles. Review the built-in profiles listed below and select a profile and use it as it is or modify it to meet your requirements. You can bind these profiles to your required services or virtual servers.

Table 1. Built-in TCP Profiles

Built-in profile	Description
nstcp_default_profile	Represents the default global TCP settings on the appliance.
nstcp_default_tcp_lan	Useful for back-end server connections, where these servers reside on the same LAN as the appliance.
nstcp_default_tcp_lan_thin_stream	Similar to the nstcp_default_tcp_lan profile; however, the settings are tuned to small size packet flows.
nstcp_default_tcp_interactive_stream	Similar to the nstcp_default_tcp_lan profile; however, it has a reduced delayed ACK timer and ACK on PUSH packet settings.
nstcp_default_tcp_lfp	Useful for long fat pipe networks (WAN) on the client side. Long fat pipe networks have long delay, high bandwidth lines with minimal packet drops.
nstcp_default_tcp_lfp_thin_stream	Similar to the nstcp_default_tcp_lfp profile; however, the settings are tuned for small size packet flows.
nstcp_default_tcp_lnp	Useful for long narrow pipe networks (WAN) on the client side. Long narrow pipe networks have considerable packet loss once in a while.
nstcp_default_tcp_lnp_thin_stream	Similar to the nstcp_default_tcp_lnp profile; however, the settings are tuned for small size packet flows.
nstcp_internal_apps	Useful for internal applications on the appliance (for example, GSLB sitesyncing). This contains tuned window scaling and SACK options for the desired applications. This profile should not be bound to applications other than internal applications.
nstcp_default_Mobile_profile	Useful for mobile devices.
nstcp_default_XA_XD_profile	Useful for a XenApp or XenDesktop deployment.

Sample TCP Configurations

Sample command line interface examples for configuring the following:

- Defending TCP against spoofing attacks
- Explicit Congestion Notification (ECN)
- Selective ACKnowledgment (SACK)
- Forward ACKnowledgment (FACK)
- Window Scaling (WS)
- Maximum Segment Size (MSS)
- NetScaler to learn the MSS of a virtual server
- TCP keep-alive
- Buffer size - using TCP profile
- Buffer size - using TCP buffering feature
- MPTCP
- Congestion control
- Dynamic receive buffering

Defending TCP against spoofing attacks

Enable the NetScaler to defend TCP against spoof attacks. By default the "rstWindowAttenuation" parameter is disabled. This parameter is enabled to protect the appliance against spoofing. If you enable, it will reply with corrective acknowledgement (ACK) for an invalid sequence number. Possible values are Enabled, Disabled.

Where RST window attenuation parameter protects the appliance against spoofing. When enabled, will reply with corrective ACK when a sequence number is invalid.

```
> set ns tcpProfile profile1 -rstWindowAttenuate ENABLED -spoofSynDrop ENABLED
 Done
> set lb vserver lbvserver1 -tcpProfileName profile1
 Done
```

Explicit Congestion Notification (ECN)

Enable ECN on the required TCP profile.

```
> set ns tcpProfile profile1 -ECN ENABLED
 Done
> set lb vserver lbvserver1 -tcpProfileName profile1
 Done
```

Selective ACKnowledgment (SACK)

Enable SACK on the required TCP profile.

```
> set ns tcpProfile profile1 -SACK ENABLED
 Done
> set lb vserver lbvserver1 -tcpProfileName profile1
 Done
```

Forward ACKnowledgment (FACK)

Enable FACK on the required TCP profile.

```
> set ns tcpProfile profile1 -FACK ENABLED
 Done
> set lb vserver lbvserver1 -tcpProfileName profile1
 Done
```

Window Scaling (WS)

Enable window scaling and set the window scaling factor on the required TCP profile.

```
> set ns tcpProfile profile1 –WS ENABLED –WSVal 9
 Done
> set lb vserver lbvserver1 -tcpProfileName profile1
```

Done

Maximum Segment Size (MSS)

Update the MSS related configurations.

```
> set ns tcpProfile profile1 –mss 1460 - maxPktPerMss 512
 Done
> set lb vserver lbvserver1 -tcpProfileName profile1
 Done
```

NetScaler to learn the MSS of a virtual server

Enable the NetScaler to learn the VSS and update other related configurations.

```
> set ns tcpParam -learnVsvrMSS ENABLED –mssLearnInterval 180 -mssLearnDelay 3600
 Done
```

TCP keep-alive

Enable TCP keep-alive and update other related configurations.

```
> set ns tcpProfile profile1 –KA ENABLED –KaprobeUpdateLastactivity ENABLED -KAconnIdleTime 900 -KAmaxProbes 3 -KaprobeInterval 75
 Done
> set lb vserver lbvserver1 -tcpProfileName profile1
 Done
```

Buffer size - using TCP profile

Specify the buffer size.

```
> set ns tcpProfile profile1 –bufferSize 8190
 Done
> set lb vserver lbvserver1 -tcpProfileName profile1
 Done
```

Buffer size - using TCP buffering feature

Enable the TCP buffering feature (globally or for a service) and then specify the buffer size and the memory limit.

```
> enable ns feature TCPB
 Done
> set ns tcpbufParam -size 64 -memLimit 64
 Done
```

MPTCP

Enable MPTCP and then set the optional MPTCP configurations.

```
> set ns tcpProfile profile1 -mptcp ENABLED
 Done
> set ns tcpProfile profile1 -mptcpDropDataOnPreEstSF ENABLED -mptcpFastOpen ENABLED -mptcpSessionTimeout 7200
 Done
> set ns tcpparam -mptcpConCloseOnPassiveSF ENABLED -mptcpChecksum ENABLED -mptcpSFtimeout 0 -mptcpSFReplaceTimeout 10
-mptcpMaxSF 4 -mptcpMaxPendingSF 4 -mptcpPendingJoinThreshold 0 -mptcpRTOsToSwitchSF 2 -mptcpUseBackupOnDSS ENABLED
 Done
```

Congestion control

Set the required TCP congestion control algorithm.

```
> set ns tcpProfile profile1 -flavor Westwood
Done
> set lb vserver lbvserver1 -tcpProfileName profile1
Done
```

Dynamic receive buffering

Enable dynamic receive buffering on the required TCP profile.

```
> set ns tcpProfile profile1 -dynamicReceiveBuffering ENABLED
Done
> set lb vserver lbvserver1 -tcpProfileName profile1
Done
```

HTTP Configurations

Jun 03, 2015

HTTP configurations for a NetScaler appliance can be specified in an entity called an HTTP profile, which is a collection of HTTP settings. The HTTP profile can then be associated with services or virtual servers that want to use these HTTP configurations.

A default HTTP profile can be configured to set the HTTP configurations that will be applied by default, globally to all services and virtual servers.

Note: When a HTTP parameter has different values for service, virtual server, and globally, the value of the most-specific entity (the service) is given the highest precedence.
The NetScaler appliance also provides other approaches for configuring HTTP. Read on for more information.

The NetScaler supports the following HTTP capabilities:

- WebSocket protocol which allows browsers and other clients to create a bi-directional, full duplex TCP connection to the servers. The NetScaler implementation of WebSocket is RFC 6455 compliant.
- SPDY (Speedy). For more information, see SPDY.

This document includes the following details:

- Setting Global HTTP Parameters
- Setting Service or Virtual Server Specific HTTP Parameters
- Built-in HTTP Profiles
- Sample HTTP Configurations

Setting Global HTTP Parameters

Updated: 2014-08-06

The NetScaler appliance allows you to specify values for HTTP parameters that are applicable to all NetScaler services and virtual servers. This can be done using:

- Default HTTP profile
- Global HTTP command

Default HTTP profile

A HTTP profile, named as nshttp_default_profile, is used to specify HTTP configurations that will be used if no HTTP configurations are provided at the service or virtual server level.

Note:

- Not all HTTP parameters can be configured through the default HTTP profile. Some settings have to be performed by using the global HTTP command (see section below).
- The default profile does not have to be explicitly bound to a service or virtual server.

To configure the default HTTP profile

- Using the command line interface, at the command prompt enter:

  set ns httpProfile nshttp_default_profile ...

- On the configuration utility, navigate to System > Profiles, click HTTP Profiles and update nshttp_default_profile.

Global HTTP command

Another approach you can use to configure global HTTP parameters is the global HTTP command. In addition to some unique parameters, this command duplicates some parameters that can be set by using a HTTP profile. Any update made to these duplicate parameters is reflected in the corresponding parameter in the default HTTP profile.

For example, if the maxReusePool parameter is updated using this approach, the value is reflected in the maxReusePool parameter of the default HTTP profile (nshttp_default_profile).

Note: Citrix recommends that you use this approach only for HTTP parameters that are not available in the default HTTP profile.
To configure the global HTTP command

- Using the command line interface, at the command prompt enter:

  set ns httpParam ...

- On the configuration utility, navigate to System > Settings, click Change HTTP parameters and update the required HTTP parameters.

Setting Service or Virtual Server Specific HTTP Parameters

Using HTTP profiles, you can specify HTTP parameters for services and virtual servers. You must define a HTTP profile (or use a built-in HTTP profile) and associate the profile with the appropriate service and virtual server.

Note: You can also modify the HTTP parameters of default profiles as per your requirements. For more information on built-in HTTP profiles, see Built-in HTTP Profiles.

To specify service or virtual server level HTTP configurations by using the command line interface

At the command prompt, perform the following:

1. Configure the HTTP profile.
   set ns httpProfile <profile-name>...

2. Bind the HTTP profile to the service or virtual server.
   To bind the HTTP profile to the service:

   set service <name> .....

   Example:
   > set service service1 -httpProfileName profile1
   To bind the HTTP profile to the virtual server:

   set lb vserver <name> .....

   Example:
   > set lb vserver lbvserver1 -httpProfileName profile1

To specify service or virtual server level HTTP configurations by using the

configuration utility

At the configuration utility, perform the following:

1. Configure the HTTP profile.
   Navigate to System > Profiles > HTTP Profiles, and create the HTTP profile.

2. Bind the HTTP profile to the service or virtual server.
   Navigate to Traffic Management > Load Balancing > Services/Virtual Servers, and create the HTTP profile, which should be bound to the service/virtual server.

Built-in HTTP Profiles

For convenience of configuration, the NetScaler provides some built-in HTTP profiles. Review the profiles listed below and use it as it is or modify it to meet your requirements. You can bind these profiles to the required services or virtual servers.

Table 1. Built-in HTTP Profiles

Built-in profile	Description
nshttp_default_profile	Represents the default global HTTP settings on the appliance.
nshttp_default_strict_validation	Settings for deployments that require strict validation of HTTP requests and responses.

Sample HTTP Configurations

Sample command line interface examples to configure the following:

- HTTP band statistics
- WebSocket connections

HTTP band statistics

Specify the band size for HTTP requests and responses.

```
> set protocol httpBand reqBandSize 300 respBandSize 2048
Done
> show protocol httpband -type REQUEST
```

WebSocket connections

Enable webSocket on the required HTTP profile.

```
> set ns httpProfile http_profile1 -webSocket ENABLED
Done
> set lb vserver lbvserver1 -httpProfileName profile1
Done
```

Configuring HTTP/2 on the NetScaler Appliance

Nov 05, 2017

Note: The HTTP/2 functionality is supported on the NetScaler MPX, VPX, and SDX models. For NetScaler VPX, the HTTP/2 functionality is supported from 11.0 release onwards.

The problem with web application performance is directly related to trend toward increasing the page size and the number of objects on the web pages. HTTP/1.1 was developed to support smaller web pages, slower Internet connections, and more limited server hardware than are common today. It is not well suited for newer technologies such as JavaScript and cascading style sheets (CSS), nor for new media types such as Flash videos and graphics-rich images, because it can request only one resource per connection to the server. This limitation significantly increases the number of round trips, causing longer page-rendering time and reduced network performance.

The HTTP/2 protocol addresses these limitations by allowing communication to occur with less data transmitted over the network, and providing the ability to send multiple requests and responses across a single connection. At its core, HTTP/2 addresses the key limitations of HTTP/1.1 by using the underlying network connections more efficiently. It changes the way requests and responses travel over the network.

HTTP/2 is a binary protocol. It is more efficient to parse, more compact on the wire, and most importantly, it is less error-prone, compared to textual protocols like HTTP/1.1. The HTTP/2 protocol uses a binary framing layer that defines the frame type and how HTTP messages are encapsulated and transferred between the client and server.

The HTTP/2 protocol includes a lot of performance-enhancing changes that significantly improve performance, particularly for clients connecting over a mobile network.

The following table lists the major improvements in HTTP/2 over HTTP/1.1:

HTTP/2 Features	Description
Header Compression	HTTP headers have a lot of repetitive information and therefore consume unnecessary bandwidth during data transmission. HTTP/2 reduces bandwidth requirements by compressing the header and minimizing the requirement to transport HTTP headers with every request and response.
Connection Multiplexing	Latency can have a huge impact on page load times and the end user experience. Connection multiplexing overcomes this problem by sending multiple requests and responses across a single connection.
Server Push	Server push enables the server to proactively push content to the client browser, avoiding round trip delay. This feature caches the responses it thinks the client will need, reduces the number round trips, and improves the page rendering time. **Important**: The NetScaler appliance does not support the server push functionality.
No Head-of-line Blocking	Under HTTP/1.1, browsers can download one resource at a time per connection. When a browser has to download a large resource, it blocks all other resources from downloading until the first download is complete. HTTP/2 overcomes this problem with a multiplexing approach. It allows the client browser to download other web components in parallel over the same connection and display them as they become available.
Request Prioritization	Not all resources have equal priority when the browser renders a web page. To accelerate the load time, all modern browsers prioritize requests by type of asset, their location on the page, and even by learned priority from previous visits. With HTTP/1.1, the browser has limited ability to leverage the priority data, because this protocol does not support multiplexing, and there is no way to communicate request prioritization by the server. The result is unnecessary network latency. HTTP/2 overcomes this problem by allowing the browser to dispatch all requests. The browser can communicate its stream prioritization preference via stream dependencies and weights, enabling the servers to optimize response delivery. **Important**: The NetScaler appliance does not support the request prioritization functionality.

How HTTP/2 Works on a NetScaler appliance

A NetScaler appliance supports HTTP/2 connections with clients. It converts the HTTP/2 headers to HTTP/1.1 for communication with servers. When a service or virtual server associated with a profile configured for HTTP/2 receives a request from a client, the NetScaler appliance accumulates the HTTP/2 headers and decodes them to form HTTP/1.1 headers. After decoding the headers, the appliance validates the HTTP/1.1 headers and ensures that the data is intact. Once the validation is complete, the appliance forwards the HTTP/1.1 headers to the server.

When the appliance receives the response headers from the server, it converts all the HTTP/1.1 headers to HTTP/2 headers and sends them to the client.

Note: HTTP/2 over SSL through ALPN is supported only between HTTP/2 client and NetScaler and not from NetScaler to the back-end server. Also, for ALPN+HTTP/2 requests, the appliance acts as a gateway.

HTTP/2 over an SSL (HTTPS) virtual server

If the HTTP/2 setting is enabled on the HTTP profile associated with an HTTPS virtual server, the NetScaler appliance uses the TLS ALPN extension (RFC 7301) to determine whether the HTTP client supports HTTP/2. If it does, the appliance chooses HTTP/2 as the application-layer protocol to transmit data between the client and the server NetScaler appliance (as described in RFC 7540 - Section 3.3).

The appliance uses the following order of preference when choosing the application-layer protocol through the TLS ALPN extension:

- HTTP/2 (if enabled in the HTTP profile)
- SPDY (if enabled in the HTTP profile)
- HTTP/1.1

HTTP/2 over an HTTP virtual server

If the HTTP/2 setting is enabled on the HTTP profile associated with the HTTP virtual server, the NetScaler appliance uses the HTTP protocol upgrade mechanism (as described in RFC 7540 - Section 3.2) to upgrade the connection to HTTP/2. The HTTP client requests a protocol upgrade and the appliance will upgrades the connection to HTTP/2.

Note: If the HTTP/2 setting is enabled on the HTTP profile associated with the virtual server, the NetScaler appliance does ***NOT*** support the direct use of HTTP/2, but still it acts as a TCP proxy by forwarding the HTTP/2 requests to servers.

Configuring HTTP/2 on the NetScaler Appliance

The HTTP/2 feature is part of the HTTP configurations on the NetScaler appliance. By default, the HTTP/2 feature is disabled. You have to enable the feature on a specific HTTP profile and associate the HTTP profile with services or virtual servers on which you want to use the HTTP/2 feature.

To know more about binding a HTTP profile to a virtual server, see Setting Service or Virtual Server Specific HTTP Parameters section on HTTP Configuration page.

Note: The HTTP/2 functionality will not work, if User Source IP (USIP) mode is enabled and the Proxy mode is disabled on the NetScaler appliance.

To configure HTTP/2 by using the command line

At the command prompt, type:

set ns httpProfile <name> [-**http2** (ENABLED | DISABLED)] [-**http2MaxHeaderListSize** <positive_integer>] [-**http2MaxFrameSize** <positive_integer>] [-**http2MaxConcurrentStreams** <positive_integer>] [-**http2InitialWindowSize** <positive_integer>] [-**http2HeaderTableSize** <positive_integer>]

To configure HTTP/2 by using the configuration utility

1. Create a HTTP/2 profile on the NetScaler appliance. Navigate to **System** > **Profiles**, click **HTTP Profiles** and then click **Add** to create a **HTTP profile with HTTP/2** checkbox selected.

2. [Optional] Configure HTTP/2 header table size.
   Navigate to **System** > **Profiles**, select a HTTP Profile and click **Edit** to specify the maximum size of the header compression table in the **HTTP/2 Header Table Size** text box.

3. [Optional] Configure HTTP/2 initial window size
   Navigate to **System** > **Profiles**, select a HTTP Profile and click **Edit** to specify initial window size for an HTTP/2 stream in the the **HTTP/2 Initial Window Size** text box.

4. [Optional] Configure HTTP/2 maximum concurrent streams.

Navigate to **System** > **Profiles**, select a HTTP Profile and click **Edit** to specify the maximum number of concurrent streams per connection in the **HTTP/2 Maximum Concurrent Streams** text box .

5. [Optional] Configure HTTP/2 maximum frame size.
   Navigate to **System** > **Profiles**, select a HTTP Profiles and click **Edit** to specify the maximum size of the frame in the **HTTP/2 Maximum Frame Size** text box.

6. [Optional] Configure HTTP/2 maximum header list size.
   Navigate to **System** > **Profiles**, select a **HTTP Profiles** and click **Edit** to specify the header size the **Maximum Header List Size** text box.

SNMP

Nov 01, 2017

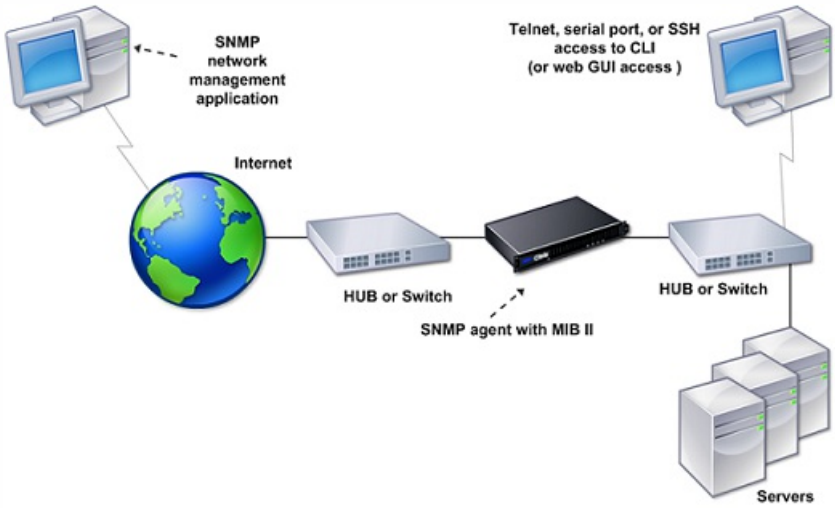
You can use Simple Network Management Protocol (SNMP) to configure the SNMP agent on the Citrix NetScaler appliance to generate asynchronous events, which are called *traps*. The traps are generated whenever there are abnormal conditions on the NetScaler. The traps are then sent to a remote device called a *trap listener*, which signals the abnormal condition on the NetScaler appliance. Or, you can query the SNMP agent for System-specific information from a remote device called an *SNMP manager*. The agent then searches the management information base (MIB) for the data requested and sends the data to the SNMP manager.

For information about SNMP parameters, traps, and its descriptions, see NetScaler SNMP OID reference.

The SNMP agent on the NetScaler can generate traps compliant with SNMPv1, SNMPv2, and SNMPv3. For querying, the SNMP agent supports SNMP version 1 (SNMPv1), SNMP version 2 (SNMPv2), and SNMP version 3 (SNMPv3).

The following figure illustrates a network with a NetScaler that has SNMP enabled and configured. In the figure, each SNMP network management application uses SNMP to communicate with the SNMP agent on the NetScaler. The SNMP agent searches its management information base (MIB) to collect the data requested by the SNMP Manager and provides the information to the application.

Figure 1. *NetScaler Supporting SNMP*



Importing MIB Files to the SNMP Manager and Trap Listener

To monitor a NetScaler appliance, you must download the MIB object definition files. The MIB files include the following:

- MIB-2 groups SYSTEM, IF, ICMP, UDP, and SNMP.
- NetScaler-specific configuration and statistics.

You can obtain the MIB object definition files from the /netscaler/snmp directory or from the Downloads tab of the NetScaler GUI.

If the SNMP management application is other than WhatsUpGold, download the following files to the SNMP management application:

- NS-MIB-smiv1.mib. Used by SNMPv1 managers and trap listeners.
- NS-MIB-smiv2.mib. Used by SNMPv2 and SNMPv3 managers and SNMPv2 trap listeners.

If the SNMP management application is WhatsUpGold, download the following files to the SNMP management application:

- mib.txt
- traps.txt

Configuring the NetScaler to Generate SNMP Traps

Sep 14, 2016

You can configure the NetScaler appliance to generate asynchronous events, which are called *traps*. The traps are generated whenever there are abnormal conditions on the appliance. The traps are sent to a remote device called a *trap listener*. This helps administrators monitor the appliance and respond promptly to any issues.

The NetScaler appliance provides a set of condition entities called *SNMP alarms*. When the condition in any SNMP alarm is met, the appliance generates SNMP trap messages that are sent to the configured trap listeners. For example, when the LOGIN-FAILURE alarm is enabled, a trap message is generated and sent to the trap listener whenever there is a login failure on the appliance.

To configure the NetScaler appliance to generate traps, you need to enable and configure alarms. Then, you specify trap listeners to which the appliance will send the generated trap messages.

This document includes the following details:

Enabling an SNMP Alarm

The NetScaler appliance generates traps only for SNMP alarms that are enabled. Some alarms are enabled by default, but you can disable them.

When you enable an SNMP alarm, the appliance generates corresponding trap messages when some events occur. Some alarms are enabled by default.

To enable an SNMP alarm by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- enable snmp alarm <trapName>
- show snmp alarm <trapName>

To enable an SNMP alarm by using the configuration utility

1. Navigate to System > SNMP > Alarms, and select the alarm.
2. Click Actions and select Enable.

Configuring Alarms

The NetScaler appliance provides a set of condition entities called *SNMP alarms*. When the condition set for an SNMP alarm is met, the appliance generates SNMP traps messages that are sent to the configured trap listeners. For example, when the LOGIN-FAILURE alarm is enabled, a trap message is generated and sent to the trap listener whenever there is a login failure on the appliance.

You can assign an SNMP alarm with a severity level. When you do this, the corresponding trap messages are assigned that severity level.

The following are the severity levels, defined on the appliance, in decreasing order of severity.

- Critical
- Major
- Minor
- Warning
- Informational

For example, if you set a warning severity level for the SNMP alarm named LOGIN-FAILURE, the trap messages generated when there is a login failure will be assigned with the warning severity level.

You can also configure an SNMP alarm to log the corresponding trap messages generated whenever the condition on that alarm is met.

To configure an SNMP alarm by using the command line interface

At the command prompt, type the following commands to configure an SNMP alarm and verify the configuration:

- set snmp alarm <trapName> [-thresholdValue <positive_integer> [-normalValue <positive_integer>]] [-time <secs>] [-state (ENABLED | DISABLED)] [-severity <severity>] [-logging (ENABLED | DISABLED)]
- show snmp alarm <trapName>

Where,

ThresholdValue: Value for the high threshold. The NetScaler appliance generates an SNMP trap message when the value of the attribute associated with the alarm is greater than or equal to the specified high threshold value.

NormalValue: Value for the normal threshold. A trap message is generated if the value of the respective attribute falls to or below this value after exceeding the high threshold.

To configure SNMP alarms by using the configuration utility

Navigate to System > SNMP > Alarms, select an alarm and configure the alarm parameters.

Configuring SNMPv1 or SNMPv2 Traps

After configuring the alarms, you need to specify the trap listener to which the appliance sends the trap messages. Apart from specifying parameters such as IP or IPv6 address and the destination port of the trap listener, you can specify the type of trap (either generic or specific) and the SNMP version.

You can configure a maximum of 20 trap listeners for receiving either generic or specific traps.

You can also configure the appliance to send SNMP trap messages with a source IP address other than the NetScaler IP (NSIP or NSIP6) address to a particular trap listener. For a trap listener that has an IPv4 address, you can set the source IP to either a mapped IP (MIP) address or a subnet IP (SNIP) address configured on the appliance. For a trap listener that has an IPv6 address, you can set the source IP to subnet IPv6 (SNIP6) address configured on the appliance.

You can also configure the appliance to send trap messages to a trap listener on the basis of a severity level. For example, if you set the severity level as Minor for a trap listener, all trap messages of the severity level equal to or greater than Minor (Minor, Major, and Critical) are sent to the trap listener.

If you have defined a community string for the trap listener, you must also specify a community string for each trap that is to be sent to the listener. A trap listener for which a community string has been defined accepts only trap messages that include a community string matching the community string defined in the trap listener. Other trap messages are dropped.

To add an SNMP trap by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp trap <trapClass> <trapDestination> -version (V1 | V2) -destPort <port> -communityName <string> -srcIP

<ip_addr> -severity <severity>

- show snmp trap

Example

```
> add snmp trap specific 10.102.29.3 -version V2 -destPort 80 -communityName com1 -severity Major
```

To configure SNMP Traps by using the configuration utility

Navigate to System > SNMP > Traps, and create the SNMP trap.

Configuring SNMPv3 Traps

SNMPv3 provides security capabilities such as authentication and encryption by using the credentials of SNMP users. An SNMP manager can receive SNMPv3 trap messages only if its configuration includes the password assigned to the SNMP user.

The trap destination can now receive SNMPv1, SNMPv2, and SNMPv3 trap messages.

To configure an SNMPv3 trap by using the command line interface

At the command prompt, do the following:

1. Add an SNMPv3 trap.
   add snmp trap <trapClass> <trapDestination> -version (V1 | V2 | V3) -destPort <port> -communityName <string> -srcIP <ip_addr> -severity <severity>

   Note: Once set, the SNMP trap version cannot not be modified.

   Example

   ```
   > add snmp trap specific 10.102.29.3 -version V3 -destPort 80 -communityName com1 -severity Major
   ```
2. Add an SNMP user.
   add snmp user <name> -group <string> [-authType (MD5 | SHA) { -authPasswd } [-privType (DES | AES) { -privPasswd }]]

   Example

   ```
   > add snmp user edocs_user -group edocs_group
   ```
3. Bind the SNMPv3 trap to the SNMP user.
   bind snmp trap <trapClass> <trapDestination> [-version <version>] (-userName <string> [-securityLevel <securityLevel>])

   Example

   ```
   > bind snmp trap specific 10.102.29.3 -version V3 -userName edocs_user -securityLevel authPriv
   ```

To configure an SNMPv3 trap by using the configuration utility

1. Add an SNMPv3 trap.
   Navigate to System > SNMP > Traps, and create the SNMP trap by selecting V3 as the SNMP version.

2. Add an SNMP user.
   Navigate to System > SNMP > Users, and create the SNMP user.

3. Bind the SNMPv3 trap to the SNMP user.
   - Navigate to System > SNMP > Traps, and select the SNMP version 3 trap.
   - Select the user to which the trap should be bound and define the appropriate Security Level.

SNMP Trap Logging

A NetScaler appliance can log SNMP trap messages (for SNMP alarms in which logging capability is enabled) when you enable the SNMP trap logging option and at least one trap listener is configured on the appliance. Now, you can specify the audit log level of trap messages sent to an external log server. The default log level is Informational. Possible values are Emergency, Alert, Critical, Error, Warning, Debug, and Notice.

For example, you can set the audit log level to Critical for an SNMP trap message generated by a logon failure. That information is then available on the NSLOG or SYSLOG server for troubleshooting.

To enable SNMP trap logging and configure trap log level by using the command line interface

At the command prompt, type the following commands to configure SNMP trap logging and verify the configuration:

- set snmp option [-snmpTrapLogging (ENABLED | DISABLED)][-snmpTrapLoggingLevel <snmpTrapLoggingLevel>]
- show snmp option

To enable SNMP trap logging and configure SNMP trap log level by using the configuration utility

Navigate to **System** > **SNMP**, click Change SNMP Options and set the following parameters:

1. SNMP Trap Logging—Select this check box to enable SNMP trap logging when at least one trap listener is configured on the appliance.
2. SNMP Trap Logging Level—Select an audit log level for the SNMP trap. By default, the audit level for SNMP trap is set to “Informational.”

Configuring the NetScaler for SNMP v1 and v2 Queries

Jun 01, 2015

You can query the NetScaler SNMP agent for system-specific information from a remote device called *SNMP managers*. The agent then searches the management information base (MIB) for the data requested and sends the data to the SNMP manager.

The following types of SNMP v1 and v2 queries are supported by the SNMP agent:

- GET
- GET NEXT
- ALL
- GET BULK

You can create strings called community strings and associate each of these to query types. You can associate one or more community strings to each query type. Community string are passwords and used to authenticate SNMP queries from SNMP managers.

For example, if you associate two community strings, such as **abc** and **bcd**, to the query type GET NEXT, the SNMP agent on the NetScaler appliance considers only those GET NEXT SNMP query packets that contain **abc** or **bcd** as the community string.

This document includes the following details:

Specifying an SNMP Manager

Updated: 2014-08-06

You must configure the NetScaler appliance to allow the appropriate SNMP managers to query it. You must also provide the SNMP manager with the required NetScaler-specific information. You can add up to a maximum of 100 SNMP managers or networks.

For an IPv4 SNMP manager you can specify a host name instead of the manager's IP address. If you do so, you must add a DNS name server that resolves the host name of the SNMP manager to its IP address. You can add up to a maximum of five host-name based SNMP managers.

Note: The appliance does not support use of host names for SNMP managers that have IPv6 addresses. You must specify the IPv6 address.
If you do not configure at least one SNMP manager, the appliance accepts and responds to SNMP queries from all IP addresses on the network. If you configure one or more SNMP managers, the appliance accepts and responds only to SNMP queries from those specific IP addresses.

If you remove an SNMP manager from the configuration, that manager can no longer query the appliance.

To add SNMP managers by specifying IP addresses by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp manager <IPAddress> ... [-netmask <netmask>]
- show snmp manager

Example

```
> add snmp manager 10.102.29.10 10.102.29.15 10.102.29.30
```

To add an SNMP manager by specifying its host name by using the command line interface

Important: If you specify the SNMP manager's host name instead of its IP address, you must configure a DNS name server to resolve the host name to the SNMP manager's IP address. For more information, see "Adding a Name Server."
At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp manager <IPAddress> [-domainResolveRetry **<integer>]**
- show snmp manager

Example

```
> add nameserver 10.103.128.15

> add snmp manager engwiki.eng.example.net –domainResolveRetry 10
```

To add an SNMP manager by using the configuration utility

1. Navigate to System > SNMP > Managers, and create the SNMP manager.
   Important: If you specify the SNMP manager's host name instead of its IPv4 address, you must configure a DNS name server to resolve the host name to the SNMP manager's IP address. For more information, see "Adding a Name Server."
   Note: The appliance does not support host names for SNMP managers that have IPv6 addresses.

Specifying an SNMP Community

You can create strings called community strings and associate them with the following SNMP query types on the appliance:

- GET
- GET NEXT
- ALL
- GET BULK

You can associate one or more community strings to each query types. For example, when you associate two community strings, such as **abc** and **bcd**, to the query type GET NEXT, the SNMP agent on the appliance considers only those GET NEXT SNMP query packets that contain **abc** or **bcd** as the community string.

If you do not associate any community string to a query type then the SNMP agent responds to all SNMP queries of that type.

To specify an SNMP community by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp community <communityName> <permissions>

- show snmp community

Example

```
> add snmp community com all
```

To configure an SNMP community string by using the configuration utility

Navigate to System > SNMP > Community, and create the SNMP community.

Configuring the NetScaler for SNMPv3 Queries

Nov 05, 2017

Simple Network Management Protocol Version 3 (SNMPv3) is based on the basic structure and architecture of SNMPv1 and SNMPv2. However, SNMPv3 enhances the basic architecture to incorporate administration and security capabilities, such as authentication, access control, data integrity check, data origin verification, message timeliness check, and data confidentiality.

To implement message level security and access control, SNMPv3 introduces the user-based security model (USM) and the view-based access control model (VACM).

- **User-Based Security Model.** The user-based security model (USM) provides message-level security. It enables you to configure users and security parameters for the SNMP agent and the SNMP manager. USM offers the following features:
  - **Data integrity:** To protect messages from being modified during transmission through the network.
  - **Data origin verification:** To authenticate the user who sent the message request.
  - **Message timeliness:** To protect against message delays or replays.
  - **Data confidentiality:** To protect the content of messages from being disclosed to unauthorized entities or individuals.
- **View-Based Access Control Model.** The view-based access control model (VACM) enables you to configure access rights to a specific subtree of the MIB based on various parameters, such as security level, security model, user name, and view type. It enables you to configure agents to provide different levels of access to the MIB to different managers.

The Citrix NetScaler supports the following entities that enable you to implement the security features of SNMPv3:

- SNMP Engines
- SNMP Views
- SNMP Groups
- SNMP Users

These entities function together to implement the SNMPv3 security features. Views are created to allow access to subtrees of the MIB. Then, groups are created with the required security level and access to the defined views. Finally, users are created and assigned to the groups.

Note: The view, group, and user configuration are synchronized and propagated to the secondary node in a high availability (HA) pair. However, the engine ID is neither propagated nor synchronized as it is unique to each NetScaler appliance.
To implement message authentication and access control, you need to:

- Set the Engine ID
- Configure Views
- Configure Groups
- Configure Users

Setting the Engine ID

Updated: 2014-08-06

SNMP engines are service providers that reside in the SNMP agent. They provide services such as sending, receiving, and authenticating messages. SNMP engines are uniquely identified using engine IDs.

The NetScaler appliance has a unique engineID based on the MAC address of one of its interfaces. It is not necessary to

override the engineID. However, if you want to change the engine ID, you can reset it.

To set the engine ID by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- set snmp engineId <engineID>
- show snmp engineId

Example

```
> set snmp engineId 8000173f0300c095f80c68
```

To set the engine ID by using configuration utility

Navigate to System > SNMP > Users, click Configure Engine ID and type an engine ID.

Configuring a View

Updated: 2014-08-06

SNMP views restrict user access to specific portions of the MIB. SNMP views are used to implement access control.

To add an SNMP view by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp view <name> <subtree> -type (included | excluded)
- show snmp view <name>

Where,

Name. Name for the SNMPv3 view. It can consist of 1 to 31 characters that include uppercase and lowercase letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters. You should choose a name that helps identify the SNMPv3 view.

Subtree. A particular branch (subtree) of the MIB tree that you want to associate with this SNMPv3 view. You must specify the subtree as an SNMP OID. This is an argument of maximum Length: 99.

type. Include or exclude the subtree, specified by the subtree parameter, in or from this view. This setting can be useful when you have included a subtree, such as A, in an SNMPv3 view and you want to exclude a specific subtree of A, such as B, from the SNMPv3 view. This is a mandatory argument. Possible values: included, excluded.

To configure an SNMP view by using the configuration utility

Navigate to System > SNMP > Views, and create the SNMP view.

Configuring a Group

Updated: 2014-08-06

SNMP groups are logical aggregations of SNMP users. They are used to implement access control and to define the security levels. You can configure an SNMP group to set access rights for users assigned to that group, thereby restricting the users to specific views.

You need to configure an SNMP group to set access rights for users assigned to that group.

To add an SNMP group by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp group <name> <securityLevel> -readViewName <string>
- show snmp group <name> <securityLevel>

Where,

Name. Name for the SNMPv3 group. Can consist of 1 to 31 characters that include uppercase and lowercase letters, numbers, and the hyphen (-), period (.) pound (#), space ( ), at sign (@), equals (=), colon (:), and underscore (_) characters. You should choose a name that helps identify the SNMPv3 group.

securityLevel. Security level required for communication between the NetScaler appliance and the SNMPv3 users who belong to the group. Specify one of the following options:

noAuthNoPriv. Require neither authentication nor encryption.

authNoPriv. Require authentication but no encryption.

authPriv. Require authentication and encryption. Note: If you specify authentication, you must specify an encryption algorithm when you assign an SNMPv3 user to the group. If you also specify encryption, you must assign both an authentication and an encryption algorithm for each group member. This is a mandatory argument. Possible values: noAuthNoPriv, authNoPriv, authPriv.

readViewName. Name of the configured SNMPv3 view that you want to bind to this SNMPv3 group. An SNMPv3 user bound to this group can access the subtrees that are bound to this SNMPv3 view as type INCLUDED, but cannot access the ones that are type EXCLUDED. If the NetScaler appliance has multiple SNMPv3 view entries with the same name, all such entries are associated with the SNMPv3 group. This is a mandatory argument. Maximum Length: 31

To configure an SNMP group by using the configuration utility

Navigate to System > SNMP > Groups, and create the SNMP group.

Configuring a User

Updated: 2014-08-06

SNMP users are the SNMP managers that the agents allow to access the MIBs. Each SNMP user is assigned to an SNMP group.

You need to configure users at the agent and assign each user to a group.

To configure a user by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add snmp user <name> -group <string> [-authType (MD5 | SHA) {-authPasswd } [-privType (DES | AES) {-privPasswd }]]
- show snmp user <name>

Where,

authType is the authentication option available while configuring an user. There are two authentication types such as MD5 and SHA.

privType is the encryption option available while configuring an user. There are two types of encryption such as DES of key size 128 bit, and AES of key size 128 bit.

Example

```
> add snmp user edocs_user -group edocs_group
```

To configure an SNMP user by using the configuration utility

Navigate to System > SNMP > Users, and create the SNMP user.

Configuring SNMP Alarms for Rate Limiting

Aug 24, 2016

Citrix NetScaler appliances such as the NetScaler MPX 10500, 12500, and 15500 are rate limited. The maximum throughput (Mbps) and packets per second (PPS) are determined by the license purchased for the appliance. For rate-limited platforms, you can configure SNMP traps to send notifications when throughput and PPS approach their limits and when they return to normal.

Throughput and PPS are monitored every seven seconds. You can configure traps with high-threshold and normal-threshold values, which are expressed as a percentage of the licensed limits. The appliance then generates a trap when throughput or PPS exceeds the high threshold, and a second trap when the monitored parameter falls to the normal threshold. In addition to sending the traps to the configured destination device, the NetScaler logs the events associated with the traps in the /var/log/ns.log file as EVENT ALERTSTARTED and EVENT ALERTENDED.

Exceeding the throughput limit can result in packet loss. You can configure SNMP alarms to report packet loss.

For more information about SNMP alarms and traps, see "Configuring the NetScaler to generate SNMP v1 and v2 Traps."

This document includes the following details:

Configuring an SNMP Alarm for Throughput or PPS

Updated: 2014-08-12

To monitor both throughout and PPS, you must configure seperate alarms and set threshold pps value in Mbps.

To configure an SNMP alarm for the throughput rate by using the command line interface

At the command prompt, type the following commands to configure the SNMP alarm, set threshold value in Mbps and verify the configuration:

- set snmp alarm PF-RL-RATE-THRESHOLD [-thresholdValue <positive_integer> [-normalValue <positive_integer>]] [-state (**ENABLED** | **DISABLED**)] [-severity <severity>] [-logging (**ENABLED** | **DISABLED**)]
- show snmp alarm PF-RL-RATE-THRESHOLD

Example

```
> set snmp alarm PF-RL-RATE-THRESHOLD -thresholdValue 70 -normalValue 50
```

To configure an SNMP alarm for PPS by using the command line interface

At the command prompt, type the following commands to configure the SNMP alarm for PPS and verify the configuration:

- set snmp alarm PF-RL-PPS-THRESHOLD [-thresholdValue <positive_integer> [-normalValue <positive_integer>]] [-state (**ENABLED** | **DISABLED**)] [-severity <severity>] [-logging (**ENABLED** | **DISABLED**)]
- show snmp alarm PF-RL-PPS-THRESHOLD

Example

```
> set snmp alarm PF-RL-PPS-THRESHOLD -thresholdValue 70 -normalValue 50
```

To configure an SNMP alarm for throughput or PPS by using the configuration utility

1. Navigate to System > SNMP > Alarms, and select PF-RL-RATE-THRESHOLD (for throughput rate) or PF-RL-PPS-THRESHOLD (for packets per second).

2. Set the alarm parameters and enable the selected SNMP alarm.

Configuring SNMP Alarm for Dropped Packets

Updated: 2014-08-12

You can configure an alarm for packets dropped as a result of exceeding the throughput limit and an alarm for packets dropped as a result of exceeding the PPS limit.

To configure an SNMP alarm for packets dropped because of excessive throughput, by using the command line interface

At the command prompt, type:
set snmp alarm PF-RL-RATE-PKTS-DROPPED [-state (**ENABLED** | **DISABLED**)] [-severity <severity>] [-logging (**ENABLED** | **DISABLED**)]

To configure an SNMP alarm for packets dropped because of excessive PPS, by using the command line interface

At the command prompt, type:
set snmp alarm PF-RL-PPS-PKTS-DROPPED [-state (**ENABLED** | **DISABLED**)] [-severity <severity>] [-logging (**ENABLED** | **DISABLED**)]

To configure an SNMP alarm for dropped packets by using the configuration utility

1. Navigate to System > SNMP > Alarms, and select PF-RL-RATE-PKTS-DROPPED (for packets dropped because of excessive throughput) or PF-RL-PPS-PKTS-DROPPED (for packets dropped because of excessive PPS).
2. Set the alarm parameters and enable the selected SNMP alarm.

Configuring SNMP in FIPS Mode

Dec 22, 2016

FIPS mode requires Simple Network Management Protocol version 3 (SNMPv3) with the authentication and privacy (authPriv) option. SNMP version 1 and version 2 use a community string mechanism to provide secured access to management data. The community string is sent as clear text between an SNMP manager and an SNMP agent. This type of communication is unsecure, allowing intruders to access SNMP information on the network.

The SNMPv3 protocol uses the User-based Security Model (USM) and View-based Access Control Model (VACM) to authenticate and control management access to SNMP messaging data. SNMPv3 has three security levels: no authentication no privacy (noAuthNoPriv), authentication and no privacy (authNoPriv), and authentication and privacy (authPriv).

Enabling FIPS mode and restarting the NetScaler appliance removes the following SNMP configurations from the appliance:

1. Community configuration for SNMPv1 and SNMPv2 protocols.
2. SNMPv3 groups configured with the noAuthNoPriv or authNoPriv security-level option.
3. Traps configured for SNMPv1 or SNMPv2, or SNMPv3 with the noAuthNoPriv security-level option.

After restarting the appliance, configure SNMPv3 with the authPriv option. For more information about configuring authPriv option in SMNP v3, see Configuring-snmpv3-queries.

Note: Enabling FIPS mode and restarting your appliance blocks execution of the following SNMP trap and group commands:

command COPY

```
1. add snmp community <communityName> <permissions>

2. add snmp trap <trapClass> <trapDestination> ... [-version: v1/v2]   [-td <positive_integer>] [-destPort <port>] [-communityName <string

3. add snmp group <name> <securityLevel : noAuthNoPriv/ authNoPriv > -readViewName <string>

4. bind snmp trap specific <TrapIp>-userName <v3 user name> -securityLevel <noAuthNoPriv/ authNoPriv>
```

Audit Logging

Jun 03, 2015

Auditing is a methodical examination or review of a condition or situation. The Audit Logging feature enables you to log the NetScaler states and status information collected by various modules in the kernel and in the user-level daemons. For audit logging, you can use the SYSLOG protocol, the native NSLOG protocol, or both.

SYSLOG is a standard protocol for logging. It has two components: the SYSLOG auditing module, which runs on the NetScaler appliance, and the SYSLOG server, which can run on the underlying FreeBSD operating system (OS) of the NetScaler appliance or on a remote system. SYSLOG uses user data protocol (UDP) for data transfer.

Similarly, the native NSLOG protocol has two components— the NSLOG auditing module, which runs on the NetScaler appliance, and the NSLOG server, which can run on the underlying FreeBSD OS of the NetScaler appliance or on a remote system. NSLOG uses transmission control protocol (TCP) for data transfer.

When you run a SYSLOG or NSLOG server, it connects to the NetScaler appliance. The NetScaler appliance then starts sending all the log information to the SYSLOG or NSLOG server, and the server can filter the log entries before storing them in a log file. An NSLOG or SYSLOG server can receive log information from more than one NetScaler appliance, and a NetScaler appliance can send log information to more than one SYSLOG server or NSLOG server.

If multiple SYSLOG servers are configured, the NetScaler appliance send its SYSLOG events and messages to all the configured external log servers. This results in storing redundant messages and makes monitoring difficult for system administrators. To address this issue, the NetScaler appliance offers load balancing algorithms that can load balance the SYSLOG messages among the external log servers for better maintenance and performance. The supported load balancing algorithms include RoundRobin, LeastBandwidth, CustomLoad, LeastPackets, and AuditlogHash.

The log information that a SYSLOG or NSLOG server collects from a NetScaler appliance is stored in a log file in the form of messages. These messages typically contain the following information:

- The IP address of a NetScaler appliance that generated the log message
- A time stamp
- The message type
- The predefined log levels (Critical, Error, Notice, Warning, Informational, Debug, Alert, and Emergency)
- The message information

To configure audit logging, you first configure the audit modules on the NetScaler appliance. That involves creating audit policies and specifying the NSLOG server or SYSLOG server information. You then install and configure the SYSLOG or the NSLOG server on the underlying FreeBSD OS of the NetScaler appliance or on a remote system.

Note: Because SYSLOG is an industry standard for logging program messages, and various vendors provide support, this documentation does not include SYSLOG server configuration information.
The NSLOG server has its own configuration file (auditlog.conf). You can customize logging on the NSLOG server system by making additional modifications to the configuration file (auditlog.conf).

Configuring the NetScaler Appliance for Audit Logging

Oct 26, 2017

Auditing module allows logging of all states and status information from different modules so that an administrator can see event history in the chronological order. Main components of Audit framework are 'audit action', 'audit policy'. 'Audit action' describes Audit Server configuration information whereas 'audit policy' links a bind entity to an 'audit action'. The audit policies use 'Classic Policy Engine'(CPE) framework to link 'audit action' to 'bind entities' or Progress Integration (PI) framework to link 'audit action' to 'system global bind entities'.

The policy frameworks differ from each other in the way the audit-log policies are bound to the global entities. Previously, the audit module supported only Classic expression but now it supports both Classic and Advanced policy expressions. Currently, the Advanced expression can bind audit-log policies only to System global entities.

Note: When binding a policy to global entities, you must bind a policy it to a system global entity of the same expression type. For example, you cannot bind a classic policy to an advanced global entity or bind an advanced policy to a classic global entity.

Configuring Audit-log Policies in a Classic Policy Expression

Configuring audit-logging in Classic policy consists of the following steps:

1. **Configuring an audit-log action**. You can configure an audit action for different servers and for different log levels. 'Audit action' describes Audit Server configuration information whereas 'audit policy' links a bind entity to an 'audit action'. By default, the SYSLOG and NSLOG uses only TCP to transfer log information to the log servers. TCP is more reliable than UDP for transferring complete data. When using TCP for SYSLOG, you can set the buffer limit on the NetScaler appliance to store the logs. After the after which the logs are sent to the SYSLOG server.
2. **Configuring audit-log policy**. Configure SYSLOG policies to log messages to a SYSLOG server, and/or NSLOG policy to log messages to an NSLOG server. Each policy includes a rule identifying the messages to be logged, and a SYSLOG or NS LOG action.
3. **Binding audit-log policies to global entities**. You must globally bind the audit log policies to global entities such SYSTEM, VPN, AAA etc., to enable logging of all NetScaler system events. By defining the priority level, you can set the evaluation order of the audit server logging. Priority 0 is the highest and is evaluated first. The higher the priority number, the lower is the priority of evaluation.

Each of these steps are explained in the following sections.

Configuring audit-log action

To configure SYSLOG action in Advanced Policy infrastructure by using the command line interface.

Note: The NetScaler appliance allows you to configure only one SYSLOG action to SYSLOG server IP address and port. The appliance does not allow you to configure multiple SYSLOG actions to the same server IP address and port.

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add audit syslogAction <name> <serverIP> [-serverPort <port>] -logLevel <logLevel> [-dateFormat (MMDDYYYY | DDMMYYYY)] [-transport (TCP | UDP)]
- show audit syslogAction [<name>]

To configure NSLOG action in Advanced Policy infrastructure by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add audit nslogAction <name> <serverIP> [-serverPort <port>] -logLevel <logLevel> [-dateFormat (MMDDYYYY | DDMMYYYY)]
- show audit nslogAction [<name>]

Configuring audit-log Policies

To configure audit-log Policies in Classic Policy infrastructure by using the command line interface

At the command prompt, type:

- add audit syslogpolicy <name> <-rule> <action>
- add audit nslogpolicy <name> < rule> < action >rm audit nslogpolicy <name>show audit nslogpolicy [<name>]set audit nslogpolicy <name> [-rule <expression >] [-action <name>]

Binding audit-log policies to global entities

To bind audit-log policy in Classic policy framework by using the command line interface

At the command prompt, type:

bind auditlog systemglobal <auditlog policy> -globalType SYSTEM -priority

Configuring Audit-log Policies using Advanced Policy Expression

Configuring audit-logging in Advanced policy consists of the following steps:

1. **Configuring an audit-log action**. You can configure an audit action for different servers and for different log levels. 'Audit action' describes Audit Server configuration information whereas 'audit policy' links a bind entity to an 'audit action'. By default, the SYSLOG and NSLOG uses only TCP to transfer log information to the log servers. TCP is more reliable than UDP for transferring complete data. When using TCP for SYSLOG, you can set the buffer limit on the NetScaler appliance to store the logs. After the after which the logs are sent to the SYSLOG server.
2. **Configuring audit-log policy**. Configure SYSLOG policies to log messages to a SYSLOG server, and/or NSLOG policy to log messages to an NSLOG server. Each policy includes a rule identifying the messages to be logged, and a SYSLOG or NS LOG action.
3. **Binding audit-log policies to global entities**. You must globally bind the audit log policies to SYSTEM global entity to enable logging of all NetScaler system events. By defining the priority level, you can set the evaluation order of the audit server logging. Priority 0 is the highest and is evaluated first. The higher the priority number, the lower is the priority of evaluation.

Configuring audit-log action

To configure syslog action in Advanced Policy infrastructure by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add audit syslogAction <name> <serverIP> [-serverPort <port>] -logLevel <logLevel> [-dateFormat (MMDDYYYY | DDMMYYYY)] [-transport (TCP | UDP)]
- show audit syslogAction [<name>]

To configure NSLOG action in Advanced Policy infrastructure by using the command line interface

At the command prompt, type the following commands to set the parameters and verify the configuration:

- add audit nslogAction <name> <serverIP> [-serverPort <port>] -logLevel <logLevel> [-dateFormat (MMDDYYYY | DDMMYYYY)]
- show audit nslogAction [<name>]

Configuring audit-log Policies

To add a syslog audit action by using the command line interface

At the command prompt, type:

Adding an Syslog Audit action COPY

```
add audit syslogAction <name> (<serverIP> | ((<serverDomainName>[-domainResolveRetry <integer>])

| -lbVserverName <string>))[-serverPort <port>] -logLevel <logLevel>[-dateFormat <dateFormat>]

 [-logFacility <logFacility>][-tcp ( NONE | ALL )] [-acl ( ENABLED | DISABLED )]

[-timeZone ( GMT_TIME | LOCAL_TIME )][-userDefinedAuditlog ( YES | NO )]

 [-appflowExport ( ENABLED | DISABLED )] [-lsn ( ENABLED | DISABLED )][-alg ( ENABLED | DISABLED )]

[-subscriberLog ( ENABLED | DISABLED )][-transport ( TCP | UDP )] [-tcpProfileName <string>][-maxLogDataSizeToHold
```

To add a nslog audit action by using the command line interface

At the command prompt, type:

Adding Nslog Audit action COPY

```
add audit nslogAction <name> (<serverIP> | (<serverDomainName>[-domainResolveRetry <integer>])) [-serverPort <port>]       -logLevel
```

Binding audit-log policies to global entities

To bind syslog audit-log policy in Advanced policy framework by using the command line interface

At the command prompt, type:

Binding Syslog Audit-log policy COPY

```
bind auditlog sysloggglobal <auditlog policy> -globalType SYSTEM -priority

bind auditlog nslogglobal <auditlog policy> -globalType SYSTEM –priority
```

Configuring audit-log policy by using the NetScaler GUI

1. Navigate to **Configuration** > **System** > **Auditing** > **Syslog** and then to **Policies** tab page to bind a syslog policy (advanced or classic) to system global entity. **Note**: System global can be either in “Classic” or “Advanced” mode. In “Classic” mode, you can bind only a classic audit-log policy and when in “Advanced” mode, you can bind only an advanced audit-log policy.
2. Select a policy and click **Action** to select a system global binding (Advanced or Classic) from the drop-down list.
3. In the **Auditing Syslog Classic Policy Global Binding** page, select a syslog policy and click **Add Binding** to bind the policy to system global entities (in Classic or Advance mode).

Sample Audit-log Configuration COPY

```
> add audit syslogaction audit-action1 10.102.1.1 -loglevel INFORMATIONAL -dateformat MMDDYYYY

> add audit nslogAction nslog-action1 10.102.1.3 -serverport 520 -loglevel INFORMATIONAL -dateFormat MMDDYYYY

> add audit syslogpolicy syslog-pol1 ns_true audit-action1

> add audit nslogPolicy nslog-pol1 ns_true nslog-action1

> bind system global nslog-pol1 -priority 20
```

Configuring Policy-Based Logging

You can configure policy-based logging for rewrite and responder policies. Audit messages are then logged in a defined format when the rule in a policy evaluates to TRUE. To configure policy-based logging, you configure an audit-message action that uses default syntax expressions to specify the format of the audit messages, and associate the action with a policy. The policy can be bound either globally or to a load balancing or content switching virtual server. You can use audit-message actions to log messages at various log levels, either in syslog format only or in both syslog and newnslog formats

Pre Requisites

- User Configurable Log Messages (userDefinedAuditlog) option is enabled for when configuring the audit action server to which you want to send the logs in a defined format.
- The related audit policy is bound to system global.

Configuring an Audit Message Action

You can configure audit message actions to log messages at various log levels, either in syslog format only or in both syslog and newnslog formats. Audit-message actions use expressions to specify the format of the audit messages.

To create an audit message action by using the command line interface

At the command prompt, type:

add audit messageaction <name> <logLevel> <stringBuilderExpr> [-logtoNewnslog (YES | NO)] [-bypassSafetyCheck (YES | NO)]

Example COPY

```
> add audit messageaction log-act1 CRITICAL '"Client:"+CLIENT.IP.SRC+" accessed "+HTTP.REQ.URL' -bypassSafetyCheck YES
```

To configure an audit message action by using the configuration utility

Navigate to **System** > **Auditing** > **Message Actions**, and create the audit message action.

Binding Audit Message Action to a Policy

After you have created an audit message action, you must bind it to a rewrite or responder policy. For more information about binding log message actions to a rewrite or responder policy, see "Rewrite" or "Responder".

Installing and Configuring the NSLOG Server

Jul 23, 2015

During installation, the NSLOG server executable file (auditserver) is installed along with other files. The auditserver executable file includes options for performing several actions on the NSLOG server, including running and stopping the NSLOG server. In addition, you use the auditserver executable to configure the NSLOG server with the IP addresses of the NetScaler appliances from which the NSLOG server will start collecting logs. Configuration settings are applied in the NSLOG server configuration file (auditlog.conf).

Then, you start the NSLOG server by executing the auditserver executable. The NSLOG server configuration is based on the settings in the configuration file. You can further customize logging on the NSLOG server system by making additional modifications to the NSLOG server configuration file (auditlog.conf).

Attention: The version of the NSLOG server package must be the same as that of the NetScaler. For example, if the version of the NetScaler is 10.1 Build 125.9, the NSLOG server must also be of the same version.
The following table lists the operating systems on which the NSLOG server is supported.

Table 1. Supported Platforms for the NSLOG Server

Operating system	Software requirements	Remarks
Windows	• Windows XP Professional • Windows Server 2003 • Windows 2000/NT • Windows Server 2008 • Windows Server 2008 R2	
Linux	• RedHat Linux 4 or later • SUSE Linux Enterprise 9.3 or later	
FreeBSD	FreeBSD 6.3 or later	For NetScaler 10.5, use only FreeBSD 8.4.
Mac OS	Mac OS 8.6 or later	Not supported on NetScaler 10.1 and later releases.

The minimum hardware specifications for the platform running the NSLOG server are as follows:

- Processor- Intel x86 ~501 megahertz (MHz)
- RAM - 512 megabytes (MB)
- Controller - SCSI

This document includes the following details:

Installing NSLOG Server on the Linux Operating System

Log on to the Linux system as an administrator. Use the following procedure to install the NSLOG server executable files on the system.

To install the NSLOG server package on a Linux operating system

1. At a Linux command prompt, type the following command to copy the NSauditserver.rpm file to a temporary directory:
   cp <path_to_cd>/Utilities/auditserver/Linux/NSauditserver.rpm /tmp
2. Type the following command to install the NSauditserver.rpm file:
   rpm -i NSauditserver.rpm

   This command extracts the files and installs them in the following directories:

   - /usr/local/netscaler/etc
   - /usr/local/netscaler/bin
   - /usr/local/netscaler/samples

To uninstall the NSLOG server package on a Linux operating system

1. At a command prompt, type the following command to uninstall the audit server logging feature:
   rpm -e NSauditserver
2. For more information about the NSauditserver RPM file, use the following command:
   rpm -qpi *.rpm
3. To view the installed audit server files use the following command:
   rpm -qpl *.rpm

   *.rpm: Specifies the file name.

Installing NSLOG Server on the FreeBSD Operating System

Before you can install the NSLOG server, you have to copy the NSLOG package from the NetScaler product CD or download it from www.citrix.com. The NSLOG package has the following name format:

AuditServer_<release number>-<build number>.zip

For example: AuditServer_10.5-58.11.zip

This package contains files for all supported platforms: Linux, Windows, and FreeBSD. On a FreeBSD operating system, install the NSLOG package that has the following name format:

audserver_bsd-<release number>-<build number>.tgz

For example: audserver_bsd-10.5-58.11.tgz

To download NSLOG package from www.citrix.com

1. In a web browser, go to www.citrix.com.
2. In the menu bar, click **Log In**.
3. Enter your login credentials, and then click **Log In**.
4. In the menu bar, click **Downloads**.
5. From the **Select a product** list, select **NetScaler ADC**.
6. On the **NetScaler ADC** page, select the release for which you want to download the NSLOG package (for example, Release 10.5), and then select **Firmware**.
7. Under **Firmware**, select the NetScaler firmware for the build number for which you want to download the NSLOG package.
8. On the page that appears, scroll down, select **Audit Servers**, and click **Download File** next to the package that you want to download.

To install the NSLOG server package on a FreeBSD operating system

1. On the system to which you have downloaded the NSLOG package AuditServer_<release number>-<build number>.zip (for example, AuditServer_9.3-51.5.zip), extract the FreeBSD NSLOG server package audserver_bsd-<release number>-<build number>.tgz (for example, audserver_bsd-9.3-51.5.tgz) from the package.
2. Copy the FreeBSD NSLOG server package audserver_bsd-<release number>-<build number>.tgz (for example, audserver_bsd-9.3-51.5.tgz) to a directory on a system running FreeBSD OS.
3. At a command prompt for the directory into which the FreeBSD NSLOG server package was copied, run the following command to install the package:
   pkg_add audserver_bsd-<release number>-<build number>.tgz

   Example
   pkg_add audserver_bsd-9.3-51.5.tgz
   The following directories are extracted:

   - <root directory extracted from the FreeBSD NSLOG server package tgz file>\netscaler\bin (for example, /var/auditserver/netscaler/bin)
   - <root directory extracted from the FreeBSD NSLOG server package tgz file>\netscaler\etc (for example, /var/auditserver/netscaler/etc)
   - <root directory extracted from the FreeBSD NSLOG server package tgz file>\netscaler\samples (for example, /var/auditserver/samples)
4. At a command prompt, type the following command to verify that the package is installed:
   pkg_info | grep NSaudserver

To uninstall the NSLOG server package on a FreeBSD operating system

At a command prompt, type:

pkg_delete NSaudserver

Installing NSLOG Server Files on the Windows Operating System

Before you can install the NSLOG server, you have to copy the NSLOG package from the NetScaler product CD or download it from www.citrix.com. The NSLOG package has the following name format AuditServer _<release number>-<build number>.zip (for example, AuditServer_9.3-51.5.zip). This package contains NSLOG installation packages for all

supported platforms.

To download NSLOG package from www.Citrix.com

1. In a web browser, go to www.citrix.com.
2. In the menu bar, click Log In.
3. Enter your login credentials, and then click Log In.
4. In the menu bar, click Downloads.
5. Search to find the page that provides the appropriate release number and build.
6. On that page, under Audit Servers, click Download to download the NSLOG package, having the format AuditServer_<release number>-<build number>.zip , to your local system (for example, AuditServer_9.3-51.5.zip).

To install NSLOG server on a Windows operating system

1. On the system, where you have downloaded the NSLOG package AuditServer_<release number>-<build number>.zip (for example, AuditServer_9.3-51.5.zip), extract audserver_win-<release number>-<build number>.zip (for example, audserver_win-9.3-51.5.zip) from the package.
2. Copy the extracted file audserver_<release number>-<build number>.zip (for example, audserver_win-9.3-51.5.zip) to a Windows system on which you want to install the NSLOG server.
3. Unzip the audserver_<release number>-<build number>.zip file (for example, audserver_win-9.3-51.5.zip).
4. The following directories are extracted:
   1. <root directory extracted from the Windows NSLOG server package zip file>\bin (for example, C:\audserver_win-9.3-51.5\bin)
   2. <root directory extracted from the Windows NSLOG server package zip file>\etc (for example, C:\audserver_win-9.3-51.5\ etc)
   3. < root directory extracted from the Windows NSLOG server package zip file >\samples (for example, C:\audserver_win-9.3-51.5\ samples)
5. At a command prompt, run the following command from the <root directory extracted from the Windows NSLOG server package zip file>\bin path:
   audserver -install -f <directorypath>**auditlog.conf**

   <directorypath>: Specifies the path to the configuration file (auditlog.conf). By default, log.conf is under <root directory extracted from Windows NSLOG server package zip file>\samples directory. But you can copy auditlog.conf to your desired directory.

To uninstall the NSLOG server on a Windows operating system

At a command prompt, run the following from the <root directory extracted from Windows NSLOG server package zip file>\bin path:

audserver -remove

NSLOG Server Command Options

The following table describes the commands that you can use to configure audit server options.

Table 2. Audit Server Options

Audit server commands	Specifies
audserver -help	The available Audit Server options.
audserver -addns -f <path to configuration file>	The system that gathers the log transaction data. You are prompted to enter the IP address of the NetScaler appliance. Enter the valid user name and password.
audserver -verify -f <path to configuration file>	Check for syntax or semantic errors in the configuration file (for example, auditlog.conf).
audserver -start -f <path to configuration file>	Start audit server logging based on the settings in the configuration file (auditlog.conf). Linux only: To start the audit server as a background process, type the ampersand sign (&) at the end of the command.
audserver -stop (Linux only)	Stops audit server logging when audit server is started as a background process. Alternatively, use the Ctrl+C key to stop audit server logging.
audserver -install -f <path to configuration file> (Windows only)	Installs the audit server logging client as a service on Windows.
audserver -startservice (Windows Only)	Start the audit server logging service, when you enter this command at a command prompt. You can also start audit server logging from Start > Control Panel > Services. Note: Audit server logging starts by using the configuration settings in the configuration file, for example, auditlog.conf file specified in the audit server install option.
audserver -stopservice (Windows Only)	Stop audit server logging.
audserver -remove	Removes the audit server logging service from the registry.

Run the audserver command from the directory in which the audit server executable is present:

- On Windows: \ns\bin
- On Solaris and Linux: \usr\local\netscaler\bin

The audit server configuration files are present in the following directories:

- On Windows: \ns\etc
- On Linux: \usr\local\netscaler\etc

The audit server executable is started as ./auditserver in Linux and FreeBSD.

Adding the NetScaler Appliance IP Addresses on the NSLOG Server

In the configuration file (auditlog.conf), add the IP addresses of the NetScaler appliances whose events must be logged.

To add the IP addresses of the NetScaler appliance

At a command prompt, type the following command:

audserver -addns -f <directorypath>\auditlog.conf

<directorypath>: Specifies the path to the configuration file (auditlog.conf).

You are prompted to enter the information for the following parameters:

NSIP: Specifies the IP address of the NetScaler appliance, for example, 10.102.29.1.

Userid: Specifies the user name, for example, nsroot.

Password: Specifies the password, for example, nsroot.

If you add multiple NetScaler IP addresses (NSIP), and later you do not want to log all of the NetScaler appliance event details, you can delete the NSIPs manually by removing the NSIP statement at the end of the auditlog.conf file. For a high availability (HA) setup, you must add both primary and secondary NetScaler IP addresses to auditlog.conf by using the audserver command. Before adding the IP address, make sure the user name and password exist on the system.

Verifying the NSLOG Server Configuration File

Check the configuration file (audit log.conf) for syntax correctness to enable logging to start and function correctly.

To verify configuration, at a command prompt, type the following command:

audserver -verify -f <directorypath>\auditlog.conf

<directorypath>: Specifies the path to the configuration file (audit log.conf).

Running the NSLOG Server

Jun 20, 2013

To start audit server logging

Type the following command at a command prompt:

audserver -start -f <directorypath>\auditlog.conf
<directorypath>: Specifies the path to the configuration file (audit log.conf).

To stop audit server logging that starts as a background process in FreeBSD or Linux

Type the following command:

audserver -stop

To stop audit server logging that starts as a service in Windows

Type the following command:

audserver -stopservice

Customizing Logging on the NSLOG Server

Jun 01, 2015

You can customize logging on the NSLOG server by making additional modifications to the NSLOG server configuration file (log.conf). Use a text editor to modify the log.conf configuration file on the server system.

To customize logging, use the configuration file to define filters and log properties.

- **Log filters.** Filter log information from a NetScaler appliance or a set of NetScaler appliances.
- **Log properties.** Each filter has an associated set of log properties. Log properties define how to store the filtered log information.

This document includes the following details:

Creating Filters

Updated: 2013-11-14

You can use the default filter definition located in the configuration file (audit log.conf), or you can modify the filter or create a new filter. You can create more than one log filter.

Note: For consolidated logging, if a log transaction occurs for which there is no filter definition, the default filter is used (if it is enabled.) The only way you can configure consolidated logging of all the NetScaler appliances is by defining the default filter.

To create a filter

At the command prompt, type the following command in the configuration file (auditlog.conf) :

filter <filterName> [IP <ip>] [NETMASK <mask>] [ON | OFF]

<filterName>: Specify the name of the filter (maximum of 64 alphanumeric characters).

<ip>: Specify the IP addresses.

<mask>: Specify the subnet mask to be used on a subnet.

Specify ON to enable the filter to log transactions, or specify OFF to disable the filter. If no argument is specified, the filter is ON

Examples

filter F1 IP 192.168.100.151 ON

To apply the filter F2 to IP addresses 192.250.100.1 to 192.250.100.254:

filter F2 IP 192.250.100.0 NETMASK 255.255.255.0 ON

filterName is a required parameter if you are defining a filter with other optional parameters, such as IP address, or the combination of IP address and Netmask.

Specifying Log Properties

Updated: 2013-11-13

Log properties associated with the filter are applied to all the log entries present in the filter. The log property definition starts with the key word BEGIN and ends with END as illustrated in the following example:

```
BEGIN <filtername>
 logFilenameFormat ...
 logDirectory ...
 logInterval ...
 logFileSizeLimit ....
END
```

Entries in the definition can include the following:

- **LogFilenameFormat** specifies the file name format of the log file. The name of the file can be of the following types:
  - Static: A constant string that specifies the absolute path and the file name.
  - Dynamic: An expression that includes the following format specifiers:
    - Date (%{format}t)
    - % creates file name with NSIP

  Example

  LogFileNameFormat Ex%{%m%d%y}t.log

  This creates the first file name as Exmmddyy.log. New files are named: Exmmddyy.log.0, Exmmddyy.log.1, and so on. In the following example, the new files are crated when the file size reaches 100MB.

  Example

  LogInterval size
  LogFileSize 100
  LogFileNameFormat Ex%{%m%d%y}t

  Caution: The date format %t specified in the LogFilenameFormat parameter overrides the log interval property for that filter. To prevent a new file being created every day instead of when the specified log file size is reached, do not use %t in the LogFilenameFormat parameter.
- **logDirectory** specifies the directory name format of the log file. The name of the file can be either of the following:
  - Static: Is a constant string that specifies the absolute path and file name.
  - Dynamic: Is an expression containing the following format specifiers:
    - Date (%{format}t)
    - % creates directory with NSIP

  The directory separator depends on the operating system. In Windows, use the directory separator \.

  Example:

  LogDirectory dir1\dir2\dir3

  In the other operating systems (Linux, FreeBsd, etc.), use the directory separator /.
- **LogInterval** specifies the interval at which new log files are created. Use one of the following values:
  - Hourly: A file is created every hour. Default value.
  - Daily: A file is created very day at midnight.
  - Weekly: A file is created every Sunday at midnight.

- Monthly : A file is created on the first day of the month at midnight.
- None: A file is created only once, when audit server logging starts.
- Size: A file is created only when the log file size limit is reached.

Example

```
LogInterval Hourly
```

- **LogFileSizeLimit** specifies the maximum size (in MB) of the log file. A new file is created when the limit is reached.

  Note that you can override the loginterval property by assigning size as its value.

  The default LogFileSizeLimit is 10 MB.

  Example

  ```
  LogFileSizeLimit 35
  ```

SYSLOG Over TCP

Sep 29, 2016

Syslog is a standard for sending event notification messages. These messages can be stored locally or on an external log server. Syslog enables network administrators to consolidate log messages and derive insights from the collected data.

Syslog was originally designed to work over UDP, which can transmit a huge amount of data within the same network with minimal packet loss. However, telco operators prefer to transmit syslog data over TCP, because they need reliable, ordered data transmission between networks (for example, telco tracks user activities), and TCP provides retransmission in the event of network failure.

How Syslog over TCP works

To understand how syslog over TCP works, consider two hypothetical cases:

Sam, a network administrator, wants to log significant events on an external syslog server.

XYZ Telecom, an Internet service provider, has to transmit and store a significant amount of data on syslog servers to comply with government regulations.

In both cases, the log messages must be transmitted over a reliable channel and stored safely on an external syslog server. Unlike UDP, TCP establishes a connection, transmits messages securely, and retransmits (from sender to receiver) any data that is corrupted or lost because of network failure.

The NetScaler appliance sends log messages over UDP to the local syslog daemon, and sends log messages over TCP or UDP to external syslog servers.

SNIP support for Syslog

When the audit-log module generates syslog messages, it uses a NetScaler subnet IP (SNIP) address as the source address for sending the messages to an external syslog server. To configure a SNIP as the source address, you must make it part of the netProfile option and bind the netProfile to the syslog action.

Note: If a netProfile is not bound to a syslog action, the NetScaler IP (NSIP) is used as the source address for transmitting data to the external log server.

> Important
> Use of a SNIP address is not supported in internal logging.

FQDN Support for Audit Log

Previously, the audit-log module was configured with the destination IP address of the external syslog server to which the log messages are sent. Now, the audit-log server uses a Fully Qualified Domain Name (FQDN) instead of the destination IP address. The FQDN configuration resolves the configured domain name of the syslog server to the corresponding destination IP address for sending the log messages from the audit-log module. To resolve the domain name and avoid domain based service issues, the name server must be properly configured.

Note: When configuring a FQDN, server domain name configuration of the same NetScaler appliance in syslog action or nslog action is not supported.

Configuring Syslog over TCP by using Command Line Interface

To configure a NetScaler appliance to send syslog messages over TCP by using the command line interface

At the command prompt, type:

Adding Audit Syslog Action COPY

```
add audit syslogAction <name> (<serverIP> | ((<serverDomainName>[-domainResolveRetry <integer>]) | -lbVserverName<string>))[-s
```

Example COPY

```
add audit syslogaction audit-action1 10.102.1.1 -loglevel INFORMATIONAL -dateformat MMDDYYYY -transport TCP
```

Adding SNIP IP address to netprofile option by using the Command Line Interface

To add a SNIP IP address to netprofile by using the command line interface

At the command prompt, type:

Adding SNIP IP address to netprofile COPY

```
add netProfile <name> [-td <positive_integer>] [-srcIP <string>][-srcippersistency ( ENABLED | DISABLED )][-overrideLsn ( ENABLED | DI
```

Example COPY

```
add netprofile net1 –srcip 10.102.147.204
```

where, srcIP is the SNIP.

Adding netprofile in a syslog action by using the Command Line Interface

To add a netProfile option in a syslog action by using the command line interface

At the command prompt, type:

Adding netprofile in a syslog action COPY

```
add audit syslogaction <name> (<serverIP> | -lbVserverName <string>)  -logLevel <logLevel>

-netProfile <string> …
```

Example COPY

```
add syslogaction sys_act1 10.102.147.36 –loglevel all –netprofile net1
```

Where -net Profile specifies the name of the configured net profile. The SNIP address is configured as part of the netProfile and this netProfile option is bound to the syslog action.

Note: You must always bind the netProfile option to the SYSLOGUDP or SYSLOGTCP services bound to the SYSLOGUDP or SYSLOGTCP load balancing virtual server when LB vserver name is configured in syslogaction.

Configuring FQDN support by using the Command Line Interface

To add a server domain name to a Syslog action by using the command line interface

At the command prompt, type:

Adding Server Domain Name COPY

```
add audit syslogAction <name> (<serverIP> | ((<serverDomainName>[-domainResolveRetry <integer>]) | -lbVserverName <string>)) -log

set audit syslogAction <name> [-serverIP <ip_addr|ipv6_addr|*>]-serverDomainName <string>] [-lbVserverName <string>]-domainResolv
```

To add a server domain name to a Nslog action by using the command line interface.

At the command prompt, type:

Adding a server domain name to a Nslog action COPY

```
add audit nslogAction <name> (<serverIP> | (<serverDomainName>[-domainResolveRetry <integer>]))  -logLevel <logLevel> ...

set audit nslogAction <name> [-serverIP <ip_addr|ipv6_addr|*>][-serverDomainName <string>] [-domainResolveRetry <integer>][-domain
```

Where

<serverDomainName> is the domain name of the log server. This is mutually exclusive with serverIP/ lbVserverName.

-domainResolveRetry<integer> is the time (in seconds) that the NetScaler appliance waits, after a DNS resolution fails, before sending the next DNS query to resolve the domain name.

-domainResolveNow is included if the DNS query has to be sent immediately to resolve the server's domain name.

Configuring Syslog over TCP by using the NetScaler GUI

To configure the NetScaler appliance to send Syslog messages over TCP by using the NetScaler GUI

1. Navigate to **System** > **Auditing** > **Syslog** and select the **Servers** tab.
2. Click **Add** and select Transport Type as **TCP**.

Configuring netprofile for SNIP support by using the NetScaler GUI

To configure netprofile for SNIP support by using the NetScaler GUI

1. Navigate to **System** > **Auditing** > **Syslog** and select the **Servers** tab.
2. Click **Add** and select a netprofile from the list.

Configuring FQDN by using the NetScaler GUI

To configure FQDN by using the NetScaler GUI

1. Navigate to **System** > **Auditing** > **Syslog** and select the **Servers** tab.
2. Click **Add** and select a Server Type and Server Domain Name from the list.

Load Balancing SYSLOG Servers

Oct 09, 2016

The NetScaler appliance send its SYSLOG events and messages to all the configured external log servers. This results in storing redundant messages and makes monitoring difficult for system administrators. To address this issue, the NetScaler appliance offers load balancing algorithms that can load balance the SYSLOG messages among the external log servers for better maintenance and performance. The supported load balancing algorithms include RoundRobin, LeastBandwidth, CustomLoad, LeastConnection, LeastPackets, and AuditlogHash.

Load balancing of SYSLOG servers using the command line interface

At the command prompt, type:

1. Add a service and specify the service type as SYSLOGTCP or SYSLOGUDP.
   add service <name>(<IP> | <serverName>) <serviceType (SYSLOGTCP | SYSLOGUDP)> <port>
2. Add a load balancing virtual server, specify the service type as SYSLOGTCP or SYSLOGUDP, and load balancing method as AUDITLOGHASH.
   add lb vserver <name> <serviceType (SYSLOGTCP | SYSLOGUDP)> [-lbMethod <AUDITLOGHASH>]
3. Bing the service to the load balancing virtual server.
   Bind lb vserver <name> <serviceName>
4. Add a SYSLOG action and specify the load balancing server name that has SYSLOGTCP or SYSLOGUDP as service type.
   add syslogaction <name> <serverIP> [-lbVserverName <string>] [-logLevel <logLevel>]
5. Add a SYSLOG policy by specifying the rule and action.
   add syslogpolicy <name> <rule> <action>
6. Bind the SYSLOG policy to the system global for the policy to take effect.
   bind system global <policyName>

Load balancing of SYSLOG servers using the configuration utility

1. Add a service and specify the service type as SYSLOGTCP or SYSLOGUDP.
   Navigate to **Traffic Management** > **Services**, click **Add** and select **SYLOGTCP** or **SYSLOGUDP** as protocol.
2. Add a load balancing virtual server, specify the service type as SYSLOGTCP or SYSLOGTCP, and load balancing method as AUDITLOGHASH.
   Navigate to **Traffic Management** > **Virtual Servers**, click **Add** and select **SYLOGTCP** or **SYSLOGUDP** as protocol.
3. Bing the service to the load balancing virtual server to the service.
   Bing the service to the load balancing virtual server.

   Navigate to **Traffic Management** > **Virtual Servers**, select a virtual server and then select **AUDITLOGHASH** in the **Load Balancing Method.**
4. Add a SYSLOG action and specify the load balancing server name that has SYSLOGTCP or SYSLOGUDP as service type.
   Navigate to **System** > **Auditing**, click **Servers** and add a server by selecting **LB Vserver** option in **Servers**.
5. Add a SYSLOG policy by specifying the rule and action.
   Navigate to **System** > **Syslog**, click **Policies** and add a SYSLOG policy.

6. Bind the SYSLOG policy to the system global for the policy to take effect.
   Navigate to **System** > **Syslog**, select a SYSLOG policy and click **Action**, and then click **Global Bindings** and bind the policy to system global.

Example

The following configuration specifies load balance of SYSLOG messages among the external log servers using the AUDITLOGHASH as load balancing method. AUDITLOGHASH method load balances the traffic based on input hash value from the audit agents. The agents are the modules which generate auditlog in a NetScaler appliance. For example, if an agent LSN wants to load balance auditlogs based on client IP address, LSN module generates the hash value based on clientIP and passes the hash value to auditlog module. The auditlog module sends the auditlog messages which have same hash value to the external syslog server.

The NetScaler appliance generates SYSLOG events and messages that are load balanced amongst the services, service1, service2, and service 3.

```
add service service1 192.0.2.10 SYSLOGUDP 514
add service service2 192.0.2.11 SYSLOGUDP 514
add service service3 192.0.2.11 SYSLOGUDP 514
add lb vserver lbvserver1 SYSLOGUDP -lbMethod AUDITLOGHASH
bind lb vserver lbvserver1 service1
bind lb vserver lbvserver1 service2
bind lb vserver lbvserver1 service3
add syslogaction sysaction1 -lbVserverName lbvserver1 -logLevel All
add syslogpolicy syspol1 ns_true sysaction1
bind system global syspol1
```

Limitations

- The NetScaler appliance does not support an external load balancing virtual server load balancing the SYSLOG messages among the log servers.

Default Settings for the Log Properties

Mar 28, 2012

The following is an example of the default filter with default settings for the log properties:

```
begin default
 logInterval Hourly
 logFileSizeLimit 10
 logFilenameFormat auditlog%{%y%m%d}t.log
 end default
```

Following are two examples of defining the default filters:

Example 1

```
Filter f1 IP 192.168.10.1
```

This creates a log file for NSI 192.168.10.1 with the default values of the log in effect.

Example 2

```
Filter f1 IP 192.168.10.1
begin f1
 logFilenameFormat logfiles.log
end f1
```

This creates a log file for NSIP 192.168.10.1. Since the log file name format is specified, the default values of the other log properties are in effect.

Sample Configuration File (audit.conf)

Mar 28, 2012

Following is a sample configuration file:

```
##############################
# This is the Auditserver configuration file
# Only the default filter is active
# Remove leading # to activate other filters
##############################
MYIP <NSAuditserverIP>
MYPORT 3023
# Filter filter_nsip  IP <Specify the NetScaler IP address to filter on > ON
# begin filter_nsip
#  logInterval   Hourly
#  logFileSizeLimit  10
#  logDirectory   logdir\%A\
#  logFilenameFormat  nsip%{%d%m%Y}t.log
# end filter_nsip
Filter default
begin default
 logInterval   Hourly
 logFileSizeLimit  10
 logFilenameFormat  auditlog%{%y%m%d}t.log
end default
```

Web Server Logging

Jun 25, 2014

You can use the Web server logging feature to send logs of HTTP and HTTPS requests to a client system for storage and retrieval. This feature has two components:

- The Web log server, which runs on the NetScaler.
- The NetScaler Web Logging (NSWL) client, which runs on the client system.

When you run the NetScaler Web Logging (NSWL) client:

1. It connects to the NetScaler.
2. The NetScaler buffers the HTTP and HTTPS request log entries before sending them to the client.
3. The client can filter the entries before storing them.

To configure Web server logging, you first enable the Web logging feature on the NetScaler and configure the size of the buffer for temporarily storing the log entries. Then, you install NSWL on the client system. You then add the NetScaler IP address (NSIP) to the NSWL configuration file. You are now ready to start the NSWL client to begin logging. You can customize Web server logging by making additional modifications to the NSWL configuration file (log.conf).

Configuring the NetScaler for Web Server Logging

Oct 09, 2016

To configure the NetScaler for web server logging you are required to only enable the Web Server Logging feature. Optionally, you can perform the following configurations:

- Modify the size of the buffer (default size is 16 MB) that stores the logged information before it is sent to the NetScaler Web Logging (NSWL) client.
- Specify the custom HTTP headers that you want to export to the NSWL client. You can configure a maximum of two HTTP request and two HTTP response header names.

To configure web server logging by using the command line interface

At the command prompt, perform the following operations:

- Enable the web server logging feature.
  enable ns feature WL
- [Optional] Modify the buffer size for storing the logged information.
  set ns weblogparam -bufferSizeMB <size>

  Note: To activate your modification, you must disable and then re-enable the Web server logging feature.
- [Optional] Specify the custom HTTP header names that you want to export.
  set ns weblogparam [-customReqHdrs <string> ...] [-customRspHdrs <string> ...]

Example COPY

```
> enable ns feature WL

Done

> set ns weblogparam -bufferSizeMB 60

Done

> show ns weblogparam

    Web Logging parameters:

    Log buffer size:  60MB

    Custom HTTP request headers: (none)

    Custom HTTP response headers: (none)

Done

> set ns weblogparam -customReqHdrs req1 req2 -customRspHdrs res1 res2

Done

> show ns weblogparam

    Web Logging parameters:

    Log buffer size:  60MB

    Custom HTTP request headers: req1, req2

    Custom HTTP response headers: res1, res2

Done
```

To configure web server logging by using the configuration utility

Navigate to System > Settings and perform the following operations:

- To enable the web server logging feature, click Change Advanced Features and select Web Logging.
- To modify the buffer size, click Change Global System Settings and under Web Logging, enter the buffer size.
- To specify the custom HTTP headers to be exported, click Change Global System Settings and under Web Logging, specify the header values.

Installing the NetScaler Web Logging (NSWL) Client

Jun 01, 2015

During installation, the NSWL client executable file (nswl) is installed along with other files. The nswl executable file provides a list of options that you can use. For details, see Configuring the NSWL Client.

Attention: The version of the NSWL client must be the same as that of the NetScaler. For example, if the version of the NetScaler is 10.1 Build 125.9, the NSWL client must also be of the same version.
The following table lists the operating systems on which the NSWL client can be installed.

Table 1. Supported Platforms for the NSWL Client with hardware requirements

Operating system	Version	Hardware requirements	Remarks
Windows	• Windows XP Professional • Windows Server 2003 • Windows 2000/NT • Windows Server 2008 • Windows Server 2008 R2	Processor - Intel x86 ~501 MHz RAM - 512 MB Controller - SCSI	
Mac OS	Mac OS 8.6 or later	-	Not supported on NetScaler 10.1 and later releases.
Linux	• RedHat Linux 4 or later • SUSE Linux Enterprise 9.3 or later	Processor - Intel x86 ~501 MHz RAM - 512 MB Controller - SCSI	
Solaris	Solaris Sun OS 5.6 or later	Processor - UltraSPARC-IIi 400 MHz RAM - 512 MB Controller - SCSI	Not supported on NetScaler 10.5 and later releases.
FreeBSD	FreeBSD 6.3 or later	Processor - Intel x86 ~501 MHz RAM - 512 MB Controller - SCSI	For NetScaler 10.5, use only FreeBSD 8.4.

Operating system	Version	Hardware requirements	Remarks
AIX	AIX 6.1		Not supported on NetScaler 10.5 and later releases.

If the NSWL client system cannot process the log transaction because of a CPU limitation, the Web log buffer overruns and the logging process reinitiates.

Caution: Reinitiation of logging can result in loss of log transactions.
To temporarily solve a NSWL client system bottleneck caused by a CPU limitation, you can tune the Web server logging buffer size on the NetScaler appliance. To solve the problem, you need a client system that can handle the site's throughput.

This document includes the following details:

- Downloading the NSWL Client
- Installing the NSWL Client on a Solaris System
- Installing the NSWL Client on a Linux System
- Installing the NSWL Client on a FreeBSD System
- Installing the NSWL Client on a Mac System
- Installing the NSWL Client on a Windows System
- Installing the NSWL Client on a AIX System

Downloading the NSWL Client

Updated: 2014-06-25

You can obtain the NSWL client package from either the NetScaler product CD or the Citrix downloads site. Within the package there are separate installation packages for each supported platforms.

To download the NSWL client package from the Citrix site

1. Open the URL: https://www.citrix.com/downloads.html.
2. Log in to the site using your credentials.
3. Open the page for the required release number and build.
4. In the page, under Weblog Clients, click Download. The package has the name format as follows: Weblog-<release number>-<build number>.zip.

Installing the NSWL Client on a Solaris System

Updated: 2014-06-25

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the nswl_solaris-<release number>-<build number>.tar file from the package.
2. Copy the extracted file to a Solaris system on which you want to install the NSWL client.
3. Extract the files from the tar file with the following command:
   tar xvf nswl_solaris-9.3-51.5.tar
   A directory NSweblog is created in the temporary directory, and the files are extracted to the NSweblog directory.
4. Install the package with the following command:
   pkgadd -d
   The list of available packages appears. In the following example, one NSweblog package is shown:

1 NSweblog NetScaler Weblogging (SunOS,sparc) 7.0

5. You are prompted to select the packages. Select the package number of the NSweblog to be installed.
   After you select the package number and press Enter, the files are extracted and installed in the following directories:
   - /usr/local/netscaler/etc
   - /usr/local/netscaler/bin
   - /usr/local/netscaler/samples
6. To check whether the NSWL package is installed, execute the following command:
   pkginfo | grep NSweblog
   Note: To uninstall the NSWL package, execute the following command:
   pkgrm NSweblog

Installing the NSWL Client on a Linux System

Updated: 2014-06-25

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the nswl_linux-<release number>-<build number>.rpm file from the package.
2. Copy the extracted file to a system, running Linux OS, on which you want to install the NSWL client.
3. To install the NSWL package, execute the following command:
   rpm -i nswl_linux-9.3-51.5.rpm
   This command extracts the files and installs them in the following directories.
   - /usr/local/netscaler/etc
   - /usr/local/netscaler/bin
   - /usr/local/netscaler/samples
   Note: To uninstall the NSWL package, execute the following command:
   rpm -e NSweblog
   Note: To get more information about the NSweblog RPM file, execute the following command:
   rpm -qpi *.rpm
   Note: To view the installed Web server logging files, execute the following command:
   rpm -qpl *.rpm

Installing the NSWL Client on a FreeBSD System

Updated: 2014-06-25

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the nswl_bsd-<release number>-<build number>.tgz file from the package.
2. Copy the extracted file to a system, running FreeBSD OS, on which you want to install the NSWL client.
3. To install the NSWL package, execute the following command:
   pkg_add nswl_bsd-9.3-51.5.tgz
   This command extracts the files and installs them in the following directories.
   - /usr/local/netscaler/etc
   - /usr/local/netscaler/bin
   - /usr/local/netscaler/samples
   Note: To uninstall the NSWL package, execute the following command:
   pkg_delete NSweblog
4. To verify that the package is installed, execute the following command:

pkg_info | grep NSweblog

Installing the NSWL Client on a Mac System

Updated: 2014-06-25

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the nswl_macos-<release number>-<build number>.tgz file from the package.
2. Copy the extracted file to a system, running Mac OS, on which you want to install the NSWL client.
3. To install the NSWL package, execute the following command:
   pkg_add nswl_macos-9.3-51.5.tgz
   This command extracts the files and installs them in the following directories:
   - /usr/local/netscaler/etc
   - /usr/local/netscaler/bin
   - /usr/local/netscaler/samples

   Note: To uninstall the NSWL package, execute the following command:
   pkg_delete NSweblog
4. To verify that the package is installed, execute the following command:
   pkg_info | grep NSweblog

Installing the NSWL Client on a Windows System

Updated: 2014-09-18

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the nswl_win-<release number>-<build number>.zip file from the package.
2. Copy the extracted file to a Windows system on which you want to install the NSWL client.
3. On the Windows system, unzip the file in a directory (referred as <NSWL-HOME>). The following directories are extracted: bin, etc, and samples.
4. At the command prompt, run the following command from the <NSWL-HOME>\bin directory:
   nswl -install -f <directorypath>\log.conf
   where,

   <directorypath> refers to the path of the configuration file (log.conf). By default, the file is in the <NSWL-HOME>\etc directory. However, you can copy the configuration file to any other directory.

   Note: To uninstall the NSWL client, at the command prompt, run the following command from the <NSWL-HOME>\bin directory:
   > nswl -remove

Installing the NSWL Client on a AIX System

Updated: 2014-06-25

To install the NSWL client, perform the following operations on the system where you downloaded the package.

1. Extract the nswl_aix-<release number>-<build number>.rpm file from the package.
2. Copy the extracted file to a system, running AIX OS, on which you want to install the NSWL client.
3. To install the NSWL package, execute the following command:
   rpm -i nswl_aix-9.3-51.5.rpm

This command extracts the files and installs them in the following directories.

- /usr/local/netscaler/etc
- /usr/local/netscaler/bin
- /usr/local/netscaler/samples

Note: To uninstall the NSWL package, execute the following command:

```
rpm -e NSweblog
```

Note: To get more information about the NSweblog RPM file, execute the following command:

```
rpm -qpi *.rpm
```

Note: To view the installed Web server logging files, execute the following command:

```
rpm -qpl *.rpm
```

Configuring the NSWL Client

Jun 01, 2015

After installing the NSWL client, you can configure the NSWL client using the nswl executable. These configurations are then stored in the NSWL client configuration file (log.conf).

Note: You can further customize logging on the NSWL client system by making additional modifications to the NSWL configuration file (log.conf). For details, see Customizing Logging on the NSWL Client System.
The following table describes the commands that you can use to configure the NSWL client.

NSWL command	Specifies
nswl -help	The available NSWL help options.
nswl -addns -f <path-to-configuration-file>	The system that gathers the log transaction data. You are prompted to enter the IP address of the NetScaler appliance. Enter a valid user name and password.
nswl -verify -f <path-to-configuration-file>	Check for syntax or semantic errors in the configuration file.
nswl -start -f <path-to-configuration-file>	Start the NSWL client based on the settings in the configuration file. Note: For Solaris and Linux: To start Web server logging as a background process, type the ampersand sign (&) at the end of the command.
nswl -stop (Solaris and Linux only)	Stop the NSWL client if it was started as a background process; otherwise, use CTRL+C to stop Web server logging.
nswl -install -f <path-to-configuration-file> (Windows only)	Install the NSWL client as a service in Windows.
nswl -startservice (Windows only)	Start the NSWL client by using the settings in the configuration file specified in the nswl install option. You can also start NSWL client from Start > Control Panel > Services. **Note:** The NSWL log files will be created in **C:\Windows\SysWOW64**
nswl -stopservice (Windows only)	Stops the NSWL client.
nswl -remove	Remove the NSWL client service from the registry.

Run the following commands from the directory in which the NSWL executable is located:

- Windows: \ns\bin
- Solaris and Linux: \usr\local\netscaler\bin

The Web server logging configuration files are located in the following directory path:

- Windows: \ns\etc

- Solaris and Linux: \usr\local\netscaler\etc

The NSWL executable is started as .\nswl in Linux and Solaris.

This document includes the following details:

Adding the IP Addresses of the NetScaler Appliance

Updated: 2013-07-17

In the NSWL client configuration file (log.conf), add the NetScaler IP address (NSIP) from which the NSWL client will start collecting logs.

To add the NSIP address of the NetScaler appliance

1. At the client system command prompt, type:

   nswl -addns -f < directorypath > \log.conf

   < directorypath >: Specifies the path to the configuration file (log.conf).

2. At the next prompt, enter the following information:

   - **NSIP**: Specify the IP address of the NetScaler appliance.
   - Username and Password: Specify the nsroot user credentials of the NetScaler appliance.

Note: If you add multiple NetScaler IP addresses (NSIP), and later you do not want to log all of NetScaler system log details, you can delete the NSIPs manually by removing the NSIP statement at the end of the log.conf file. During a failover setup, you must add both primary and secondary NetScaler IP addresses to the log.conf by using the command. Before adding the IP address, make sure the user name and password exist on the NetScaler appliances.

Verifying the NSWL Configuration File

To make sure that logging works correctly, check the NSWL configuration file (log.conf) on the client system for syntax errors.

To verify the configuration in the NSWL configuration file

At the client system command prompt, type:

nswl -verify -f <directorypath>\log.conf

< directorypath >: Specifies the path to the configuration file (log.conf).

Running the NSWL Client

To start Web server logging

At the client system command prompt, type:

nswl -start -f <directorypath>\log.conf
<directorypath>: Specifies the path to the configuration file (log.conf).

To stop Web server logging started as a background process on the Solaris or Linux operating systems

At the command prompt, type:

```
nswl -stop
```

To stop Web server logging started as a service on the Windows operating system

At the command prompt, type:

```
nswl -stopservice
```

Customizing Logging on the NSWL Client System

Feb 13, 2017

You can customize logging on the NSWL client system by making additional modifications to the NSWL client configuration file (log.conf). Use a text editor to modify the log.conf configuration file on the client system.

To customize logging, use the configuration file to define filters and log properties.

- **Log filters.** Filter log information based on the host IP address, domain name, and host name of the Web servers.
- **Log properties.** Each filter has an associated set of log properties. Log properties define how to store the filtered log information.

This document includes the following details:

Sample Configuration File

Following is a sample configuration file:

```
##########
# This is the NSWL configuration file
# Only the default filter is active
# Remove leading # to activate other filters
##########
##########
# Default filter (default on)
# W3C Format logging, new file is created every hour or on reaching 10MB file size,
# and the file name is Exyymmdd.log
##########

logFilenameFormat /ns/prod/vhost/%v/Ex%{%m%d%y}t
#end VHOST_F

########## END FILTER CONFIGURATION ##########
```

Creating Filters

Updated: 2014-01-06

You can use the default filter definition located in the configuration file (log.conf), or you can modify the filter or create a new filter. You can create more than one log filter.

Note: Consolidated logging, which logs transactions for which no filter is defined, uses the default filter if it is enabled. Consolidated logging of all servers can be done by defining only the default filter.
If the server hosts multiple Web sites and each Web site has its own domain name, and each domain is associated with a virtual server, you can configure Web server logging to create a separate log directory for each Web site. The following table displays the parameters for creating a filter.

Table 1. Parameters for Creating a Filter

Parameter	Specifies
filterName	Name of the filter. The filter name can include alphanumeric characters and cannot be longer than 59 characters. Filter names longer than 59 characters are truncated to 59 characters.
HOST name	Host name of the server for which the transactions are being logged.
IP ip	IP address of the server for which transactions are to be logged (for example, if the server has multiple domains that have one IP address).
IP ip 2...ip n:	Multiple IP addresses (for example, if the server domain has multiple IP addresses).
ip6 ip	IPv6 address of the server for which transactions are to be logged.
IP ip NETMASK mask	IP addresses and netmask combination to be used on a subnet.
ON | OFF	Enable or disable the filter to log transactions. If no argument is selected, the filter is enabled (ON).

To create a filter

To create a filter, enter the following command in the log.conf file:

- filter <filterName> <HOST name> | [IP<ip>] | [IP<ip 2...ip n>] | <IP ip NETMASK mask> [ON | OFF]
- filter <filterName> <HOST name> | [IP6 ip/<prefix length>] [ON | OFF]

To create a filter for a virtual server

To create a filter for a virtual server, enter the following command in the log.conf file:

filter <filterName> <VirtualServer IP address>
Example

In the following example, you specify an IP address of 192.168.100.0 and netmask of 255.255.255.0. The filter applies to IP addresses 192.168.100.1 through 192.168.100.254.

```
Filter F1 HOST www.netscaler.com ON
```

Filter F2 HOST www.netscaler.com IP 192.168.100.151 ON
Filter F3 HOST www.netscaler.com IP 192.168.100.151 192.165.100.152 ON
Filter F4 IP 192.168.100.151
Filter F5 IP 192.168.100.151 HOST www.netscaler.com OFF
Filter F6 HOST www.netscaler.com HOST www.xyz.com HOST www.abcxyz.com IP 192.168.100.200 ON
Filter F7 IP 192.250.100.0 NETMASK 255.255.255.0
Filter F8 HOST www.xyz.com IP 192.250.100.0 NETMASK 255.255.255.0 OFF
For creating filters for servers having IPv6 addresses.
Filter F9 2002::8/112 ON
Filter F10 HOST www.abcd.com IP6 2002::8 ON

Specifying Log Properties

Log properties are applied to all log entries associated with the filter. The log property definition begins with the keyword BEGIN and ends with END as illustrated in the following example:

```
BEGIN <filtername>
 logFormat ...
 logFilenameFormat ...
 logInterval ...
 logFileSize ....
 logExclude ....
 logTime ….
 END
```

Entries in the definition can include the following:

- **LogFormat** specifies the Web server logging feature that supports NCSA, W3C Extended, and custom log file formats.

  By default, the logformat property is w3c. To override, enter custom or NCSA in the configuration file, for example:

  ```
  LogFormat NCSA
  ```

  Note: For the NCSA and custom log formats, local time is used to time stamp transactions and for file rotation.
- **LogInterval** specifies the intervals at which new log files are created. Use one of the following values:
  - Hourly: A file is created every hour.
  - Daily: A file is created every day at midnight. Default value.
  - Weekly: A file is created every Sunday at midnight.
  - Monthly: A file is created on the first day of the month at midnight.
  - None: A file is created only once, when Web server logging starts.

  Example

  ```
  LogInterval Daily
  ```
- **LogFileSizeLimit** specifies the maximum size of the log file in MB. It can be used with any log interval (weekly, monthly, and so on.) A file is created when the maximum file size limit is reached or when the defined log interval time elapses.

  To override this behavior, specify the size as the loginterval property so that a file is created only when the log file size limit is reached.

  The default LogFileSizeLimit is 10 MB.

  Example

  ```
  LogFileSizeLimit 35
  ```
- **LogFilenameFormat** specifies the file name format of the log file. The name of the file can be of the following types:
  - Static: Specifies a constant string that contains the absolute path and file name.
  - Dynamic: Specifies an expression containing the following format:
    - Server IP address (%A)
    - Date (%{format}t)
    - URL suffix (%x)
    - Host name (%v)

  Example

  ```
  LogFileNameFormat Ex%{%m%d%y}t.log
  ```

  This command creates the first file name as Exmmddyy.log, then every hour creates a file with file name: Exmmddyy.log.0, Exmmddyy.log.1,..., Exmmddyy.log.n.

  Example

  ```
  LogInterval size
  LogFileSize 100
  LogFileNameFormat Ex%{%m%d%y}t
  ```

  Caution: The date format %t specified in the LogFilenameFormat command overrides the log interval property for that filter. To prevent a new file being created every day instead of when the specified log file size is reached, do not use %t in the LogFilenameFormat.
- **LogExclude** prevents logging of transactions with the specified file extensions.

  Example

  ```
  LogExclude .html
  ```

  This command creates a log file that excludes log transactions for *.html files.
- **LogTime** specifies log time as either GMT or LOCAL.

The defaults are:

- NCSA log file format: LOCAL
- W3C log file format: GMT.

Understanding the NCSA and W3C Log Formats

The NetScaler supports the following standard log file formats:

- NCSA Common Log Format
- W3C Extended Log Format

NCSA Common Log Format

If the log file format is NCSA, the log file displays log information in the following format:

Client_IP_address -User_Name [Date:Time -TimeZone] "Method Object HTTP_version" HTTP_StatusCode BytesSent
To use the NCSA Common log format, enter NCSA in the LogFormat argument in the log.conf file.

The following table describes the NCSA Common log format.

Table 2. NCSA Common Log Format

Argument	Specifies
Client _IP_address	The IP address of the client computer.
User Name	The user name.
Date	The date of the transaction.
Time	The time when the transaction was completed.
Time Zone	The time zone (Greenwich Mean Time or local time).
Method	The request method (for example; GET, POST).
Object	The URL.
HTTP_version	The version of HTTP used by the client.
HTTP_StatusCode	The status code in the response.
Bytes Sent	The number of bytes sent from the server.

W3C Extended Log Format

An extended log file contains a sequence of lines containing ASCII characters terminated by either a Line Feed (LF) or the sequence Carriage Return Line Feed (CRLF.) Log file generators must follow the line termination convention for the platform on which they are run.

Log analyzers must accept either LF or CRLF form. Each line may contain either a directive or an entry. If you want to use the W3C Extended log format, enter W3C as the Log-Format argument in the log.conf file.

By default, the standard W3C log format is defined internally as the custom log format, shown as follows:

%{%Y-%m-%d%H:%M:%S}t %a %u %S %A %p %m %U %q %s %j %J %T %H %+{user-agent}i %+{cookie} i%+{referer}i
You can also change the order or remove some fields in this W3C log format. For example:

logFormat W3C %{%Y-%m-%d%H:%M:%S}t %m %U
W3C log entries are created with the following format:

#Version: 1.0 #Fields: date time cs-method cs-uri #Date: 12-Jun-2001 12:34 2001-06-12 12:34:23 GET /sports/football.html 2001-06-12 12:34:30 GET /sports/football.html

Entries

Entries consist of a sequence of fields relating to a single HTTP transaction. Fields are separated by white space; Citrix recommends the use of tab characters. If a field in a particular entry is not used, a dash (-) marks the omitted field.

Directives

Directives record information about the logging process. Lines beginning with the pound sign (#) contain directives.

The following table describes the directives.

Table 3. Directive Descriptions

Directive	Description
Version: <integer>.<integer>	Displays the version of the extended log file format used. This document defines version 1.0.
Fields: [<specifier>...]	Identifies the fields recorded in the log.
Software: <string>	Identifies the software that generated the log.
Start-Date: <date> <time>	Displays the date and time at which the log was started.

Directive	Description
End-Date: <date> <time>	Displays the date and time at which logging finished.
Date: <date> <time>	Displays the date and time when the entry was added.
Remark: <text>	Displays comments. Analysis tools ignore data recorded in this field.

Note: The Version and Fields directives are required. They precede all other entries in the log file.

Example

The following sample log file shows the log entries in W3C Extended log format:

#Version: 1.0 #Fields: time cs-method cs-uri #Date: 12-Jan-1996 00:00:00 00:34:23 GET /sports/football.html 12:21:16 GET /sports/football.html 12:45:52 GET /sports/football.html 12:57:34 GET /sports/fo

Fields

The Fields directive lists a sequence of field identifiers that specify the information recorded in each entry. Field identifiers may have one of the following forms:

- **identifier:** Relates to the transaction as a whole.
- **prefix-identifier:** Relates to information transfer between parties defined by the value prefix.
- **prefix (header):** Specifies the value of the HTTP header field header for transfer between parties defined by the value prefix. Fields specified in this manner always have the type <string>.

The following table describes defined prefixes.

Table 4. Prefix Descriptions

Prefix	Specifies
c	Client
s	Server
r	Remote
cs	Client to server
sc	Server to client
sr	Server to remote server (prefix used by proxies)
rs	Remote server to server (prefix used by proxies)
x	Application-specific identifier

Examples

The following examples are defined identifiers that use prefixes:

cs-method: The method in the request sent by the client to the server.

sc(Referer): The Referer field in the reply.

c-ip: The IP address of the client.

Identifiers

The following table describes the W3C Extended log format identifiers that do not require a prefix.

Table 5. W3C Extended Log Format Identifiers (No Prefix Required)

Identifier	Description
date	The date on which the transaction was done.
time	The time when the transaction is done.
time-taken	The time taken (in seconds) for the transaction to complete.
bytes	The number of bytes transferred.
cached	Records whether a cache hit has occurred. A zero indicates a cache miss.

The following table describes the W3C Extended log format identifiers that require a prefix.

Table 6. W3C Extended Log Format Identifiers (Requires a Prefix)

Identifier	Description
IP	The IP address and the port number.
dns	The DNS name.
status	The status code.

Identifier	Description
comment	The comment returned with status code.
method	The method.
url	The URL.
url-stem	The stem portion of the URL.
url-query	The query portion of the URL.

The W3C Extended Log file format allows you to choose log fields. These fields are shown in the following table.

Table 7. W3C Extended Log File Format (Allows Log Fields)

Field	Description
Date	The date on which the transaction is done.
Time	The time when the transaction is done.
Client IP	The IP address of the client.
User Name	The user name.
Service Name	The service name, which is always HTTP.
Server IP	The server IP address.
Server Port	The server port number
Method	The request method (for example; GET, POST).
Url Stem	The URL stem.
Url Query	The query portion of the URL.
Http Status	The status code in the response.
Bytes Sent	The number of bytes sent to the server (request size, including HTTP headers).
Bytes Received	The number of bytes received from the server (response size, including HTTP headers).
Time Taken	The time taken for transaction to complete, in seconds.
Protocol Version	The version number of HTTP being used by the client.
User Agent	The User-Agent field in the HTTP protocol.
Cookie	The Cookie field of the HTTP protocol.
Referer	The Referer field of the HTTP protocol.

Creating a Custom Log Format

Updated: 2013-09-30

You can customize the display format of the log file data manually or by using the NSWL library. By using the custom log format, you can derive most of the log formats that Apache currently supports.

Creating a Custom Log Format by Using the NSWL Library

Use one of the following NSWL libraries depending on whether the NSWL executable has been installed on a Windows or Solaris host computer:

- **Windows:** The nswl.lib library located in \ns\bin directory on the system manager host computer.
- **Solaris:** The libnswl.a library located in /usr/local/netscaler/bin.

To create the custom log format by using the NSWL Library

1. Add the following two C functions defined by the system in a C source file:
   ns_userDefFieldName() : This function returns the string that must be added as a custom field name in the log record.

   ns_userDefFieldVal() : This function implements the custom field value, then returns it as a string that must be added at the end of the log record.
2. Compile the file into an object file.
3. Link the object file with the NSWL library (and optionally, with third party libraries) to form a new NSWL executable.
4. Add a %d string at the end of the logFormat string in the configuration file (log.conf).

Example

########## # A new file is created every midnight or on reaching 20MB file size, # and the file name is /datadisk5/netscaler/log/NS<hostname>/Nsmmddyy.log and create digital #signature field for each

Creating a Custom Log Format Manually

To customize the format in which log file data should appear, specify a character string as the argument of the LogFormat log property definition. For more information, see Arguments for Defining a Custom Log Format. The following is an example where character strings are used to create a log format:

LogFormat Custom ""%a - "%{user-agent}i" %[%d/%m/%Y]t %U %s %b %T"

- The string can contain the “c” type control characters \n and \t to represent new lines and tabs.
- Use the <Esc> key with literal quotes and backslashes.

The characteristics of the request are logged by placing % directives in the format string, which are replaced in the log file by the values.

If the %v (Host name) or %x (URL suffix) format specifier is present in a log file name format string, the following characters in the file name are replaced by an underscore symbol in the log configuration file name:

" * . / : < > ? \ |

Characters whose ASCII values lie in the range of 0-31 are replaced by the following:

%<ASCII value of character in hexadecimal>.

For example, the character with ASCII value 22 is replaced by %16.

Caution: If the %v format specifier is present in a log file name format string, a separate file is opened for each virtual host. To ensure continuous logging, the maximum number of files that a process can have open should be sufficiently large. See your operating system documentation for a procedure to change the number of files that can be opened.

Creating Apache Log Formats

You can derive from the custom logs most of the log formats that Apache currently supports. The custom log formats that match Apache log formats are:

NCSA/combined: LogFormat custom %h %l %u [%t] "%r" %s %B "%{referer}i" "%{user-agent}i"

NCSA/Common: LogFormat custom %h %l %u [%t] "%r" %s %B

Referer Log: LogFormat custom "%{referer}i" -> %U

Useragent: LogFormat custom %{user-agent}i

Similarly, you can derive the other server log formats from the custom formats.

Arguments for Defining a Custom Log Format

Updated: 2015-04-02

The following table describes the data that you can use as the Log Format argument string:

Table 8. Custom Log Format

Argument	Specifies
%a	Remote IPv4 address.
%A	Local IPv4 address.
%a6	Remote IPv6 address.
%A6	Local IPv6 address.
%B	Bytes sent, excluding the HTTP headers (response size).
%b	Bytes received, excluding the HTTP headers (request size).
%d	User-defined field.
%e1	Value of the first custom HTTP request header.
%e2	Value of the second custom HTTP request header.
%E1	Value of the first custom HTTP response header.
%E2	Value of the second custom HTTP response header.
Note: For instructions on how to export custom HTTP headers, see Configuring the NetScaler for Web Server Logging.	
%g	Greenwich Mean Time offset (for example, -0800 for Pacific Standard Time).
%h	Remote host.
%H	Request protocol.
%{Foobar}i	Contents of the Foobar: header line(s) in the request sent to the server. The system supports the User-Agent, Referer and cookie headers. The + after the % in this format informs

Argument	Specifies
	the logging client to use the + as a word separator.
%j	Bytes received, including headers (request size)
%J	Bytes sent, including headers (response size)
%l	Remote log name (from identd, if supplied).
%m	Request method.
%M	Time taken to serve the request (in microseconds)
%{Foobar}o	Contents of Foobar: header line(s) in the reply. USER-AGENT, Referer, and cookie headers (including set cookie headers) are supported.
%p	Canonical port of the server serving the request.
%P	The admin partition.
%q	Query string (prefixed with a question mark (?) if a query string exists).
%r	First line of the request.
%s	Requests that were redirected internally, this is the status of the original request.
%t	Time, in common log format (standard English time format).
%{format}t	Time, in the form given by format, must be in the strftime(3) format. For format descriptions, see Time Format Definition.
%T	Time taken to serve the request, in seconds.
%u	Remote user (from auth; may be bogus if return status (%s) is 401).
%U	URL path requested.
%v	Canonical name of the server serving the request.
%V	Virtual server IPv4 address in the system, if load balancing, content switching, and/or cache redirection is used.
%V6	Virtual server IPv6 address in the system, if load balancing, content switching, and/or cache redirection is used.

For example, if you define the log format as %+{user-agent}i, and if the user agent value is Citrix NetScaler system Web Client, then the information is logged as NetScaler system+Web+Client. An alternative is to use double quotation marks. For example, "%{user-agent}i" logs it as "Citrix NetScaler system Web Client." Do not use the <Esc> key on strings from %.. .r, %. . .i and, %. . .o. This complies with the requirements of the Common Log Format. Note that clients can insert control characters into the log. Therefore, you should take care when working with raw log files.

Time Format Definition

Updated: 2015-04-28

The following table lists the characters that you can enter as the format part of the %{format}t string described in the Custom Log Format table of Arguments for Defining a Custom Log Format. Values within brackets ([ ]) show the range of values that appear. For example, [1,31] in the %d description in the following table shows %d ranges from 1 to 31.

Table 9. Time Format Definition

Argument	Specifies
%%	The same as %.
%a	The abbreviated name of the week day for the locale.
%A	The full name of the week day for the locale.
%b	The abbreviated name of the month for the locale.
%B	The full name of the month for the locale.
%C	The century number (the year divided by 100 and truncated to an integer as a decimal number [1,99]); single digits are preceded by a 0.

Argument	Specifies
%d	The day of month [1,31]; single digits are preceded by 0.
%e	The day of month [1,31]; single digits are preceded by a blank.
%h	The abbreviated name of the month for the locale.
%H	The hour (24-hour clock) [0,23]; single digits are preceded by a 0.
%I	The hour (12-hour clock) [1,12]; single digits are preceded by a 0.
%j	The number of the day in the year [1,366]; single digits are preceded by 0.
%k	The hour (24-hour clock) [0,23]; single digits are preceded by a blank.
%l	The hour (12-hour clock) [1,12]; single digits are preceded by a blank.
%m	The number of the month in the year [1,12]; single digits are preceded by a 0.
%M	The minute [00,59]; leading 0 is permitted but not required.
%n	Inserts a new line.
%p	The equivalent of either a.m. or p.m. for the locale.
%r	The appropriate time representation in 12-hour clock format with %p.
%S	The seconds [00,61]; the range of values is [00,61] rather than [00,59] to allow for the occasional leap second and for the double leap second.
%3	The milliseconds [000,999]; the range of values is [000,999].
%6	The microseconds [000000,999999]; the range of values is [000000,999999].
%9	The nanoseconds [000000000,999999999]; the range of values is [000000000,999999999].
%t	Inserts a tab.
%u	The day of the week as a decimal number [1,7]. 1 represents Sunday, 2 represents Tuesday and so on.
%U	The number of the week in the year as a decimal number [00,53], with Sunday as the first day of week 1.
%w	The day of the week as a decimal number [0,6]. 0 represents Sunday.
%W	Specifies the number of the week in the year as a decimal number [00,53]. Monday is the first day of week 1.
%y	The number of the year within the century [00,99]. For example, 5 would be the fifth year of that century.
%Y	The year, including the century (for example, 1993).

Note: If you specify a conversion that does not correspond to any of the ones described in the preceding table, or to any of the modified conversion specifications listed in the next paragraph, the behavior is undefined and returns 0.
The difference between %U and %W (and also between modified conversions %OU and %OW) is the day considered to be the first day of the week. Week number 1 is the first week in January (starting with a Sunday for %U, or a Monday for %W). Week number 0 contains the days before the first Sunday or Monday in January for %U and %W.

Displaying Server Logs

You can configure a NetScaler Web Logging (NSWL) feature to display server logs on the console or redirect server logs to a directory on the NetScaler appliance.

There are two ways to display logs on the console (standard output):
Option 1: Display all logs on the console.
Option 2: Display only selected logs on the console where filters with logfilenameformat as STDOUT.

Call Home

Aug 19, 2016

Note: The current NetScaler 1000V release does not support this feature.

The Call Home feature monitors your NetScaler appliance for critical error conditions. Call Home registers your appliance with the Citrix Technical Support server. If your appliance is successfully registered with the Support server, Call Home automatically uploads system data to that server in the event that one of the conditions occurs. The NetScaler Appliance keeps a full log of all upload events. If you are unable to correct the problem after reviewing the appliance's log, you can contact the Citrix Technical Support team and open a service request. The team can analyze the uploaded system data and recommend possible solutions.

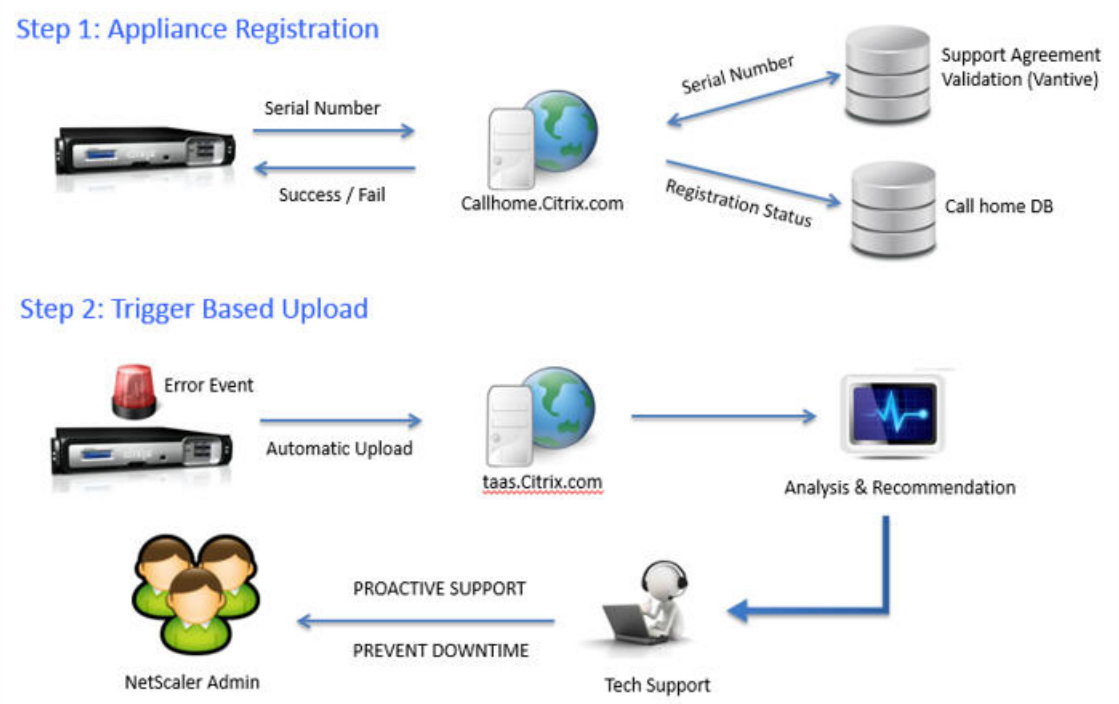
The Call Home feature is supported on all three platforms of NetScaler ADC.

- In NetScaler MPX, Call Home feature is supported on all MPX models.
- In NetScaler VPX, Call Home feature is supported only for VPX-1000 and VPX 3000 models.
  Note: CallHome support has been extended for VPX appliances that obtain their licenses from external or central licensing pools. However, the feature remains same as for a standard VPX appliance.

- In NetScaler SDX, Call Home feature is supported on VPX instances running on a SDX platform. It monitors the Hard Disk and assigned SSL chips for any errors or failures. The VPX instance however does not have access to the Power Supply Unit (PSU) and therefore CallHome does not monitor its status. In a SDX platform, you can configure CallHome either directly on an individual instance or through the SVM.

  Note: Monitoring of other SDX components is not supported.

Following is a typical setup for Call Home.



To implement Call Home, you must do the following:

- Authenticating the appliance
- Enabling Call Home
- Registering the appliance
- Uploading the system data
- Generating a service request

Authenticating the appliance. If your NetScaler appliance does not have direct Internet connectivity, you can configure a proxy server through which system logs generated by Call Home feature are uploaded to the Citrix server. When using a proxy server, Call Home provides three types of security authentication.

1. No authentication. If both the appliance and the proxy server are located at the customer end, no authentication is needed.

2. Proxy Server authentication. One-way authentication, in which the proxy server is authenticated by the NetScaler appliance. To configure one-way proxy server authentication, do the following:

1. Add an SSL service for the proxy server IP address, and enable server authentication for the service.
2. Bind a CA certificate to the service.
3. Bind an HTTPS Monitor to the service.
   When the service is up and running, it indicates that the server is authenticated, and you can proceed to the next step.
4. Set CallHome to use the newly added service

3. NetScaler and Proxy Server authentication. Two-way authentication, in which the NetScaler appliance is also authenticated. To configure a two-way authentication, do the following:

1. Add a SSL service for proxy server IP
2. Bind a CA certificate to the service.
3. Bind a Client Certificate.
4. Bind HTTPS Monitor to the service.
5. Set CallHome to use the new added service

Enabling Call Home. By default, the Citrix Call Home feature is disabled on the appliance. You must first enable the service to register the appliance for critical error conditions.

Registering a NetScaler appliance. The appliance has to be registered to the Citrix Technical Support server before Call Home can upload the system data to the server when predefined error conditions occur on the appliance.to the Citrix technical support server.

1. The Call Home process sends the following details to the Citrix Technical Support server:
   - Hardware serial number is shared for NetScaler MPX and SDX models
   - License serial number is shared for NetScaler VPX models.
2. The server checks its database for an active technical support service contract for the appliance.
3. If there is an active technical support service contract, the support server registers the NetScaler appliance for Call Home and sends a successful-registration response to the appliance stating that the feature is successfully enabled. If there is no active technical support service contract, the server sends a registration-failure response to the NetScaler appliance.

The following table lists the error conditions that Call Home currently monitors on a NetScaler appliance:

Table 1. List of error conditions monitored by Call Home

Error Condition	Indicates	Call Home Monitoring Interval	Corresponding SNMP Alarm Name
Compact flash drive errors	The compact flash drive on the appliance that encountered read or write errors.	24 hours	COMPACT-FLASH-ERRORS
Hard disk drive errors	The hard drives on the appliance that encountered read or write errors.	24 hours	HARD-DISK-DRIVE-ERRORS
Power supply unit failure	One of the power supply units on the NetScaler appliance has failed.	7 seconds	POWER-SUPPLY-FAILURE
SSL card failure	One of the SSL cards on the NetScaler appliance has failed.	7 seconds	SSL-CARD-FAILED
Warm restart	The appliance has warm restarted due to a failure of a system process.	After every restart of the NetScaler appliance.	WARM-RESTART-EVENT

Note: The Call Home feature do not monitor the power supply unit (PSU) status for VPX models and VPX instances.

Uploading appliance's data to the technical support server. An error condition triggers the following sequence of events:

1. The Call Home process checks the registration status. If the status indicates successful registration, the process advances to the next step.
2. The Call Home process runs a showtech support script that collects all of the system related data in a tar file. The data in the tar file includes configurations, logs, and statistics. Call Home locally saves the tar file at /var/tmp/support/callhome.
3. Call Home uploads a copy of the tar file to the Citrix Technical Support server. The Appliance logs the uploading of the tar file in a log file named *callhome.log* located at /var/log. You can also configure the CALLHOME-UPLOAD-EVENT SNMP alarm to generate an SNMP alert whenever Call Home uploads happen.
4. If the SNMP alarm related to the error condition is enabled, the SNMP agent on the appliance generates an SNMP trap message and sends it to all of the configured SNMP trap destinations. For more information about configuring SNMP alarms and trap destinations, see "Configuring the NetScaler to Generate SNMPv1 and SNMPv2 Traps."

Note:

- Call Home creates the Call Home tar file and uploads it to the CITRIX tech support server for only the first occurrence of a particular error condition since the appliance was last restarted. If you want the NetScaler appliance to send you alerts each time a particular error condition occurs, configure the corresponding SNMP alarm for the error condition.
- For the warm restart error condition, the Call Home tar file is uploaded to the server again only if the result of the failure is different from the result of the previous failure.

The Call Home tar file has the following name format:

collector_callhome_<NSIP of the appliance>_<P for Primary or standalone, or S for Secondary>_<date>_<hours, in 24 hr format, according to the local time zone>_<minutes>.tar.gz. For example, collector_callhome_10.105.13.100_P_2Feb2012_20_30.tar.gz.

Creating a technical support service request . After you review the logs and SNMP trap messages for Call Home upload events, you have the option of contacting the Citrix Technical Support team and opening a service request. For more information about contacting the team and opening a service request, see http://support.citrix.com/article/CTX132307.

The Support team can then analyze the system data in the uploaded Call Home tar files and sends recommendations for possible solutions to the administrator's email address.

Before you begin configuring Call Home, do the following:

- Make sure that the NetScaler appliance is connected to the Interne or to a proxy server that has internet connectivity.
- Make sure that you have an active Citrix Technical Support service contract for the appliance.

Configuring Call Home on the NetScaler appliance consists of the following tasks:

1. **Enable the Call Home feature**. When you enable the Call Home feature, the Call Home process registers the appliance with the Citrix Technical Support server. The registration takes some time to complete. During that time, the appliance displays the status as IN PROGRESS. When the registration is complete, the appliance displays the status as SUCCESSFUL.
   Note: While upgrading the NetScaler appliance from an older release to release 10.1 or later, the NetScaler appliance prompts you to enable the Call Home feature, if:
   - The Call Home feature is not supported in the older release.
   - The Call Home feature is disabled in the older release.
2. **(Optional) Specify the administrator's email address**. The Call Home process sends the email address to the Support server, where it is stored for future correspondence regarding Call Home uploads.
3. **(Optional) Specify Proxy server settings**. Netscaler appliance needs internet connectivity to upload the collector archive to the Citrix Technical Support server. If the appliance does not have internet connectivity, then a proxy server (having internet connectivity) can be configured to upload the data.
4. **(Optional) Enable the CALLHOME-UPLOAD-EVENT SNMP alarm**. The SNMP agent on the NetScaler appliance generates a trap message and sends to all the configured SNMP trap destinations. The message includes the status of uploading of the Call Home tar file by the Call Home process. For more information about configuring SNMP alarms and trap destinations, see "Configuring the NetScaler to Generate SNMPv1 and SNMPv2 Traps."
5. **(Optional) Enable all of the corresponding SNMP alarms**. Call Home creates and uploads a Call Home tar file for the first occurrence of a monitored error condition since the appliance was last restarted. If you want to be alerted of these error conditions, you can configure the corresponding SNMP alarm. Table 1 lists all the corresponding SNMP alarms. For more information about configuring SNMP alarms and trap destinations, see "Configuring the NetScaler to Generate SNMPv1 and SNMPv2 Traps."

Proactive Support for Hardware Errors

If you enable the Citrix Call Home service, it automatically generates a support case and uploads the system data to the Technical Support server if a critical hardware error, such as failure of a hard disk drive (HDD), Compact Flash (CF) device, SSL card, or power supply unit (PSU), occurs in the NetScaler appliance.

To enable Call Home by using the command line interface

At the command prompt, type any of the following:

- enable ns feature ch
- enable ns feature callhome

To configure one-way proxy server authentication by using the command interface

One Way Proxy Server Authentication COPY

```
set callhome –proxyMode Yes –proxyAuthService callhome_proxy -port 80
```

To configure two-way proxy server authentication by using the command interface

Two Way Proxy Server Authentication COPY

```
Set callhome -proxyAuthService <string> -port <port|*> -proxyMode ( YES | NO )
```

To check the status of the appliance's registration to the Support server by using the command line interface

At the command prompt, type:
show callhome
Example

```
> enable ns feature ch
Done

> show callhome
 Callhome feature: ENABLED
 Registration with Citrix upload server IN PROGRESS

 E-mail address configured:
 Proxy mode:NO   Ipaddress:     Port:0

 Trigger event              State     First occurrence   Latest occurrence
 -------------              -----     ----------------   -----------------
 1) Compact flash errors      Enabled   ..                 ..
 2) Hard disk drive errors    Enabled   ..                 ..
```

```
3) Power supply unit failure   Enabled   ..              ..
4) SSL card failure            Enabled   ..              ..
5) Warm restart                Enabled   N/A             ..
Done

> show callhome
Callhome feature: ENABLED
Registration with Citrix upload server SUCCESSFUL

E-mail address configured:
Proxy mode:NO   Ipaddress:     Port:0

Trigger event                  State     First occurrence   Latest occurrence
-------------                  -----     ----------------   -----------------
1) Compact flash errors        Enabled   ..                 ..
2) Hard disk drive errors      Enabled   ..                 ..
3) Power supply unit failure   Enabled   ..                 ..
4) SSL card failure            Enabled   ..                 ..
5) Warm restart                Enabled   N/A                ..
Done
```

To specify the administrator's email address and proxy server settings by using the command line interface

At the command prompt, type:

- set callhome -emailAddress <string>
- set callhome -proxyMode (YES | NO) [-IPAddress <ip_addr|ipv6_addr|*>] [-port <port|*>]
- show callhome

Example

```
> set callhome -emailAddress exampleadmin@example.com
Done

> set callhome –proxyMode Yes –IPAddress 10.102.167.33 –port 80
Done

> show callhome
 E-mail address configured: exampleadmin@example.com
 Proxy mode:YES   Ipaddress: 10.102.167.33      Port:80

 Trigger event                  State     First occurrence   Latest occurrence
 -------------                  -----     ----------------   -----------------
 1) Compact flash errors        Enabled   ..                 ..
 2) Hard disk drive errors      Enabled   ..                 ..
 3) Power supply unit failure   Enabled   ..                 ..
 4) SSL card failure            Enabled   ..                 ..
 5) Warm restart                Enabled   N/A                ..
```

```
Done
```

To enable Call Home proxy mode by using the command line interface

At the command prompt, type:

- set callhome -ipAddress <ipaddress> -port <port> -proxyMode [yes | no]
- show callhome

  Note: Proxy mode is enabled only when the -proxymode parameter is set to YES. If it is set to NO, the proxy functionality does not work, even if the IP address and port are configured. The port number should be for an HTTP service on the proxy server, not for an HTTPS service.

Example

```
> set callhome ipAddress 10.0.0.1 -port 80 -proxyMode yes
Done
```

To enable Proxy Server Authentication by using the configuration utility

Navigate to **System** > **Diagnostics** and under **Technical Support Tools,** select **Call Home** option to select the proxy authentication service type.

To enable Call Home by using the configuration utility

Navigate to System > Settings, click Configure Advanced Features and select the Call Home option.

To check the status of the appliance's registration with the Support server by using the configuration utility

Navigation to System > Diagnostics and, in the Technical Support Tools group, select Call Home option to view the status of registration.

To specify the administrator's email address by using the configuration utility

Navigation to System > Diagnostics and, in the Technical Support Tools group, select Call Home option to specify the administrator's email address.

To enable Call Home proxy mode by using the configuration utility

Navigation to System > Diagnostics and, in the Technical Support Tools group, select Call Home option to specify the proxy server's IP address and the port number.

To enable Call Home by using the SVM configuration utility

Navigate to **NetScaler** > **Call Home,** select a NetScaler instance and click **Enable** option.

To upload the technical support collector archive by using the NetScaler GUI

1. Navigate to **System** > **Diagnostics** page and click **Generate support** file.
2. In the **Tech Support** page, select the scope of archive from the drop-down list and select the **Upload the Collector Archive** check box to set the following options:
   1. Proxy Server (Optional) — Name of the server used for uploading the collective archive. You can use this parameter if the appliance does not have a direct internet connection or DNS configuration on this system. The basic proxy format is proxy IP:<proxy_port>. If the proxy requires authentication, the format is **username:password@proxy_IP:<proxy_port>**.
   2. Case or Service Request Number—Case serial number if the case is already opened by Citrix Technical Support.
   3. Collector Archive File—The name of the collector archive file (for example, **/var/tmp/supported/collector_P_10.102.29.200_1Jun2016_15_11.tar.gz**) to be uploaded. If the file name is specified, no new collector archive is generated.
   4. Description—A brief description about the archive upload.

5. User Name—My Citrix user name to log on to the Citrix Upload server.
6. Password—My Citrix account password to gain access into Citrix Upload server.

3. Click **Run** to automatically upload the collected archive on to the Citrix Upload server.

Reporting Tool

Feb 13, 2017

Use the Citrix® NetScaler® Reporting tool to view NetScaler performance statistics data as reports. Statistics data are collected by the nscollect utility and are stored in a database. When you want to view certain performance data over a period of time, the Reporting tool pulls out specified data from the database and displays them in charts.

Reports are a collection of charts. The Reporting tool provides built-in reports as well as the option to create custom reports. In a report, you can modify the charts and add new charts. You can also modify the operation of the data collection utility, nscollect, and stop or start its operation.

This document includes the following details:

- Using the Reporting Tool
- Working with Reports
- Working with Charts
- Examples
- Stopping and Starting the Data Collection Utility

Using the Reporting Tool

The Reporting tool is a Web-based interface accessed from the Citrix® NetScaler® appliance. Use the Reporting tool to display the performance statistics data as reports containing graphs. In addition to using the built-in reports, you can create custom reports, which you can modify at any time. Reports can have between one and four charts. You can create up to 256 custom reports.

To invoke the Reporting tool

1. Use the Web browser of your choice to connect to the IP address of the NetScaler (for example, http://10.102.29.170/). The Web Logon screen appears.
2. In the User Name text box, type the user name assigned to the NetScaler.
3. In the Password text box, type the password.
4. In the Start in drop-down box, select Reporting.
5. Click Login.

The following screen shots show the report toolbar and the chart toolbar, which are frequently referenced in this documentation.

Figure 1. *Report Toolbar*

Figure 2. *Chart Toolbar*

Working with Reports

Updated: 2013-09-27

You can plot and monitor statistics for the various functional groups configured on the NetScaler over a specified time interval. Reports enable you to troubleshoot or analyze the behavior of your appliance. There are two types of reports: built-in reports and custom reports. Report content for built-in or custom reports can be viewed in a graphical format or a

tabular format. The graphical view consists of the line, area, and bar charts that can display up to 32 sets of data (counters). The tabular view displays the data in columns and rows. This view is useful for debugging error counters.

The default report that is displayed in the Reporting tool is CPU vs. Memory Usage and HTTP Requests Rate. You can change the default report view by displaying the report you want as your default view, and then click Default Report.

Reports can be generated for the last hour, last day, last week, last month, last year, or you can customize the duration.

You can do the following with reports:

- Toggle between a tabular view of data and a graphical view of data.
- Change the graphical display type, such as bar chart or line chart.
- Customize charts in a report.
- Export the chart as an Excel comma-separated value (CSV) file.
- View the charts in detail by zooming in, zooming out, or using a drag-and-drop operation (scrolling).
- Set a report as the default report for viewing whenever you log on.
- Add or remove counters.
- Print reports.
- Refresh reports to view the latest performance data.

Using Built-in Reports

The Reporting tool provides built-in reports for frequently viewed data. Built-in reports are available for the following functional groups: System, Network, SSL, Compression, Integrated Cache, NetScaler Gateway, and Citrix NetScaler Application Firewall. By default, the built-in reports are displayed for the last day. However, you can view the reports for the last hour, last week, last month, or last year.

Note: You cannot save changes to built-in reports, but you can save a modified built-in report as a custom report.
To display a built-in report

1. In the left pane of the Reporting tool, under Built-in Reports, expand a group (for example, SSL).
2. Click a report (for example, SSL > All Backend Ciphers).

Creating and Deleting Reports

You can create your own custom reports and save them with user-defined names for reuse. You can plot different counters for different groups based on your requirements. You can create up to 256 custom reports.

You can either create a new report or save a built-in report as a custom report. By default, a newly created custom report contains one chart named System Overview, which displays the CPU Usage counter plotted for the last day. You can customize the interval and set the data source and time zone from the report toolbar. Within a report, you can use the chart toolbars to add, modify, or delete charts, as described in "Working with Charts."

By default, newly created custom reports contain one chart named System Overview that displays a CPU Usage counter plotted for the last day.

To create a custom report

1. In the Reporting tool, on the report toolbar, click Create, or if you want to create a new custom report based on an existing report, open the existing report, and then click Save As.

2. In Report Name box, type a name for the custom report.
3. Do one of the following:
   - To add the report to an existing folder, in Create in or Save in, click the down arrow to choose an existing folder, and then click OK.
   - To create a new folder to store the report, click the Click to add folder icon, in Folder Name, type the name of the folder, and in Create in, specify where you want the new folder to reside in the hierarchy, and then click OK.

   Note: You can create up to 128 folders.

To delete a custom report

1. In the left pane of the Reporting tool, next to Custom Reports, click the Click to manage custom reports icon.
2. Select the check box that corresponds with the report you want to delete, and then click Delete.

   Note: When you delete a folder, all the contents of that folder are deleted.

Modifying the Time Interval

By default, built-in reports display data for the last day. However, if you want to change the time interval for a built-in report, you can save the report as a custom report. The new interval applies to all charts in the report. The following table describes the time-interval options.

Table 1. Time Intervals

Time interval	Displays
Last Hour	Statistics data collected for the last hour.
Last Day	Statistics data collected for the last day (24 hours).
Last Week	Statistics data collected for the last week (7 days).
Last Month	Statistics data collected for the last month (31 days).
Last Year	Statistics data collected for the last year (365 days).

Time interval	Displays data collected for a time period that you are prompted to specify.
Custom	

To modify the time interval

1. In the left pane of the Reporting tool, click a report.
2. On the report toolbar, click Duration, and then click a time interval.

Setting the Data Source and Time Zone

You can retrieve data from different data sources to display them in the reports. You can also define the time zone for the reports and apply the currently displayed report's time selection to all the reports, including the built-in reports.

To set the data source and time zone

1. In the Reporting tool, on the report toolbar, click Settings.
2. In the Settings dialog box, in Data Source, select the data source from which you want to retrieve the counter information.
3. Do one or both of the following:
   - If you want the tool to remember the time period for which a chart is plotted, select the Remember time selection for charts check box.
   - If you want the reports to use the time settings of your NetScaler appliance, select the Use Appliance's time zone check box.

Exporting and Importing Custom Reports

You can share reports with other NetScaler administrators by exporting reports. You can also import reports.

To export or import custom reports

1. In the left pane of the Reporting tool, next to Custom Reports, click the Click to manage custom reports icon.
2. Select the checkbox that corresponds with the report you want to export or import, and then click Export or Import.
   Note: When you export the file, it is exported in a .gz file format.

Working with Charts

Updated: 2013-09-06

Use charts to plot and monitor counters or groups of counters. You can include up to four charts in one report. In each chart, you can plot up to 32 counters. The charts can use different graphical formats (for example, area and bar). You can move the charts up or down within the report, customize the colors and visual display for each counter in a chart, and delete a chart when you do not want to monitor it.

In all report charts, the horizontal axis represents time and the vertical axis represents the value of the counter.

Adding a Chart

When you add a chart to a report, the System Overview chart appears with the CPU Usage counter plotted for the last one day. To plot a different group of statistics or select a different counter, see "Modifying a Chart".

Note: If you add charts to a built-in report, and you want to retain the report, you must save the report as a custom report. Use the following procedure to add a chart to a report.

To add a chart to a report

1. In the left pane of the Reporting tool, click a report.
2. Under the chart where you want to add the new chart, click the Add icon.

Modifying a Chart

You can modify a chart by changing the functional group for which the statistics are displayed and by selecting different counters.

To modify a chart

1. In the left pane of the Reporting tool, click a report.
2. Under the chart that you want to modify, click Counters.
3. In the dialog box that appears, in the Title box, type a name for the chart.
4. Next to Plot chart for, do one of the following:
   - To plot counters for global counters, such as Integrated Cache and Compression, click System global statistics.
   - To plot entity counters for entity types, such as Load Balancing and GSLB, click System entities statistics.
5. In Select group, click the desired entity.
6. Under Counters, in Available, click the counter name(s) that you want to plot, and then click the > button.
7. If you selected System entities statistics in step 4, on the Entities tab, under Available, click the entity instance name(s) you want to plot, and then click the > button.
8. Click OK.

Viewing a Chart

You can specify the graphical formats of the plotted counters in a chart. Charts can be viewed as line charts, spline charts, step-line charts, scatter charts, area charts, bar charts, stacked area charts, and stacked bar charts. You can also zoom in, zoom out, or scroll inside the plot area of a chart. You can zoom in or out for all data sources for 1 hour, 1 day, 1 week, 1 month, 1 year, and 3 years.

Other options for customizing the view of a chart include customizing the axes of the charts, changing the background and edge color of the plot area, customizing the color and size of the grids, and customizing the display of each data set (counter) in a chart.

Data set numbers, such as Data Set 1, correspond to the order in which the counters in your graph are displayed at the bottom of the chart. For example, if CPU usage and Memory usage are displayed in first and second order at the bottom of the chart, CPU usage is equal to Data Set 1 and Memory usage is equal to Data Set 2.

Whenever you modify a built-in report, you need to save the report as a custom report to retain your changes.

To change the graph type of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart you want to view, on the chart toolbar, click Customize.
3. On the Chart tab, under Category, click Plot type, and then click the graph type you want to display for the chart. If you want to display the graph is 3D, select the Use 3D check box.

To refocus a chart with detailed data

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, on the report toolbar, click Zoom In, and do one or both of the following:
   - To refocus the chart to display data for a specific time window, drag and drop the cursor from the start time to the end time. For example, you can view data for a one-hour period on a certain day.
   - To refocus the chart to display data for a data point, simply click once on chart where you want to zoom in and get more detailed information.
3. Once you have the desired range of time for which you want to view detailed data, on the report toolbar, click Tabular View. Tabular view displays the data in numeric form in rows and columns.

To view numeric data for a graph

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, on the report toolbar, click Tabular View. To return to the graphical view, click Graphical View.
   Note: You can also view the numeric data in the graphical view by hovering your cursor over the notches in the gridlines.

To scroll through time in a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, on the report toolbar, click Scroll, and then click inside the chart and drag the cursor in the direction for which you want to see data for a new time period. For example, if you want to view data in the past, click and drag to the left.

To change the background color and text color of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the axes, click Customize.
3. On the Chart tab, under Category, click one or more of the following:
   - To change the background color, click Background Color, and then select the options for color, transparency, and effects.
   - To change the text color, click Text Color, and then select the options for color, transparency, and effects.

To customize the axes of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the axes, click Customize.
3. On the Chart tab, under Category, click one or more of the following:
   - To change the scale of the left y-axis, click Left Y-Axis, and then select the scale you want.
   - To change the scale of the right y-axis, click Right Y-Axis, in Data set to plot, select the date set, and then select the scale you want.
     Note: The data set numbers, such as Data Set 1, correspond to the order in which the counters in your graph are displayed at the bottom of the chart. For example, if CPU usage and Memory usage are displayed in first and second order at the bottom of the chart, CPU usage is equal to Data Set 1 and Memory usage is equal to Data Set 2.
   - To plot each data set in its own hidden y-axis, click Multiple Axes, and then click Enable.

To change the background color, edge color, and gridlines for a plot area of a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the plot area, click Customize.
3. On the Plot Area tab, under Category, click one or more of the following:

- To change the background color and edge color of the chart, click Background Color and Edge Color, and then select the options for color, transparency, and effects.
- To change the horizontal or vertical grids of the chart, click Horizontal Grids or Vertical Grids, and then select the options for displaying the grids, grid width, grid color, transparency, and effects.

To change the color and graph type of a data set

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart for which you want to customize the display of the data set (counters), click Customize.
3. On the Data Set tab, in Select Data Set, select the data set (counter) for which you want to customize the graphical display.
   Note: The data set numbers, such as Data Set 1, correspond to the order in which the counters in your graph are displayed at the bottom of the chart. For example, if CPU usage and Memory usage are displayed in first and second order at the bottom of the chart, CPU usage is equal to Data Set 1 and Memory usage is equal to Data Set 2.
4. Under Category, do one of more of the following:
   - To change the background color, click Color, and then select the options for color, transparency, and effects.
   - To change the graph type, click Plot type, and then select the graph type you want to display for the data set. If you want to display the graph as 3D, select the Use 3D check box.

Exporting Chart Data to Excel

For further data analysis, you can export charts to Excel in a comma-separated value (CSV) format.

To export chart data to Excel

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart with the data you want to export to Excel, click Export.

Deleting a Chart

If you do not want to use a chart, you can remove it from the report. You can permanently remove charts from custom reports only. If you delete a chart from a built-in report and want to retain the changes, you need to save the report as a custom report.

To delete a chart

1. In the left pane of the Reporting tool, select a report.
2. In the right pane, under the chart that you want to delete, click the Delete icon.

Examples

To display the trend report for CPU usage and memory usage for the last week

1. In the left pane of the Reporting tool, under Built-in Reports, expand System.
2. Click the report CPU vs. Memory Usage and HTTP Requests Rate.
3. In the right pane, on the report toolbar, click Duration, and then click Last Week.

To compare the bytes received rate and the bytes transmitted rate between two

interfaces for the last week

1. In the right pane, on the report toolbar, click Create.
2. In the Report Name box, type a name for the custom report (for example, Custom_Interfaces), and then click OK. The report is created with the default System Overview chart, which displays the CPU Usage counter plotted for the last hour.
3. Under System Overview, on the chart toolbar, click Counters.
4. In the counter selection pane, in Title, type a name for the chart (for example, Interfaces bytes data).
5. In Plot chart for, click System entities statistics, and then in Select Group, select Interface.
6. On the Entities tab, click the interface name(s) you want to plot (for example, 1/1 and 1/2), and then click the > button.
7. On the Counters tab, click Bytes received (Rate) and Bytes transmitted (Rate) and then click the > button.
8. Click OK.
9. On the report toolbar, click Duration, and then click Last Week.

Stopping and Starting the Data Collection Utility

Updated: 2014-09-24

The data collection utility, nscollect, runs automatically when you start the NetScaler ADC. This utility retrieves the application performance data and stores it in the form of data sources on the ADC. You can create up to 32 data sources. The default data source is /var/log/db/default.

The data collection utility creates databases for global counters and entity-specific counters, and uses this data to generate reports. Global-counter databases are created at /var/log/db/<DataSourceName> . The entity-specific databases are created based on the entities configured on the NetScaler, and a separate folder is created for each entity type in /var/log/db/<DataSourceName/EntityNameDB>.

Nscollect retrieves data once every 5 minutes. It retains data in 5-minute granularity for one day, hourly for the last 30 days, and daily for three years.

You might have to stop and restart the data collection utility if data is not updated accurately or the reports display corrupted data.

To stop nscollect

At the command prompt, type:
/netscaler/nscollect stop

To start nscollect on the current SSH session to the NetScaler:

At the command prompt, type:

/netscaler/nscollect start

To start nscollect on the local system:

At the command prompt, type:

/netscaler/nscollect start &

AutoScale

Aug 26, 2013

Efficient hosting of applications in a cloud requires continuous optimization of application availability. To meet increasing demand, you have to scale network resources upward. When demand subsides, you need to scale down to avoid the unnecessary cost of idle resources. To minimize the cost of running the application by deploying only as many instances as are necessary during any given period of time, you have to constantly monitor traffic. However, monitoring traffic manually is not a feasible option. For the application environment to be able to scale up or down rapidly, you need to automate the processes of monitoring traffic and of scaling resources up and down whenever necessary.

If your organization uses Citrix CloudPlatform to deploy and manage the cloud environment, a Citrix NetScaler appliance can automatically scale users' applications as needed. The CloudPlatform elastic load balancing feature includes a feature called *AutoScale*. A CloudPlatform user can use the AutoScale feature to specify thresholds for various conditions for automatically scaling the application fleet upward and downward. The scale-up and scale-down conditions can vary from simple use cases, such as a server's CPU usage, to complex use cases, such as a combination of a server's CPU usage and responsiveness. CloudPlatform, in turn, configures the NetScaler appliance to load balance traffic to the application virtual machines (VMs), monitor application thresholds and performance, and trigger scale-up and scale-down actions to add or remove VMs to or from the application fleet.

The CloudPlatform user performs all AutoScale configuration tasks by using the CloudPlatform user interface or APIs. The CloudPlatform user:

1. Creates a load balancing rule, with the necessary load balancing algorithm and stickiness.
2. Configures AutoScale parameters by specifying the application instance template, the minimum number of instances to maintain, the maximum number of instances permitted, scale-up and scale-down policies, and other information necessary for the functioning of the feature.
3. Submits the configuration.

For information about configuring a load balancing rule and AutoScale, see *Citrix CloudPlatform 3.0.5 (powered by Apache CloudStack) Administrator's Guide*, at http://support.citrix.com/article/CTX134823.

When the CloudPlatform user completes the AutoScale configuration, CloudPlatform uses the NetScaler NITRO API to push all the necessary configuration commands to the NetScaler appliance. As the NetScaler administrator, you do not have to perform any tasks for configuring AutoScale on the NetScaler appliance. However, you might have to be aware of certain prerequisites, and you might have to troubleshoot the configuration if issues arise in the AutoScale configuration. To troubleshoot the configuration, you have to be aware of how CloudPlatform works and what configuration CloudPlatform pushes to the NetScaler appliance. You also need a working knowledge of how to troubleshoot issues on a NetScaler appliance.

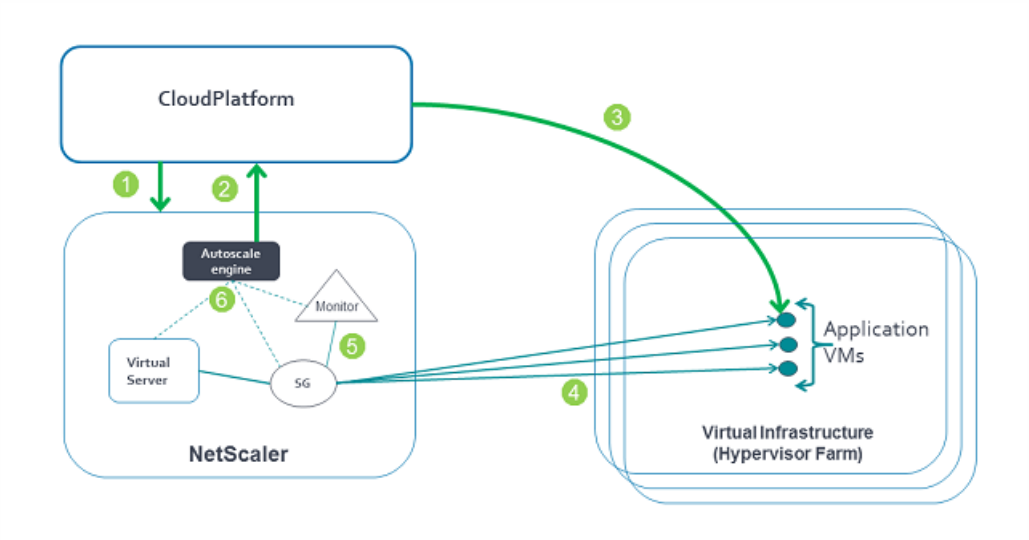
How AutoScale Works

Sep 06, 2013

When the CloudPlatform user completes the AutoScale configuration, CloudPlatform uses the NetScaler NITRO API to create an AutoScale-related configuration on the NetScaler appliance. For information about the configuration commands that CloudPlatform uses to configure the NetScaler appliance, see "NetScaler Configuration Details."

The following diagram shows the sequence of operations, beginning with CloudPlatform pushing the AutoScale configuration to the NetScaler appliance. The events are numbered in the order in which they occur, and are described below.

Figure 1. AutoScale Architecture



When the CloudPlatform user submits the AutoScale configuration, the following events occur:

1. CloudPlatform uses the NetScaler NITRO API to push the AutoScale configuration to the NetScaler appliance, creating AutoScale-related entities on the appliance. The entities include a load balancing virtual server, a service group, and monitors.
2. The AutoScale engine on the NetScaler appliance sends API requests to CloudPlatform to initially deploy the minimum number of virtual machines required.
3. CloudPlatform provisions the minimum number of instances (VMs) on the hypervisors (virtualization hosts) that it manages.
4. The NetScaler appliance discovers the IP addresses assigned by CloudPlatform to the newly created VMs and binds them, as services, to the service group representing them. The NetScaler appliance can then load balance traffic to the VMs.
5. NetScaler monitors bound to the service group start monitoring the load by collecting SNMP metrics from the instances.
6. The AutoScale engine on the NetScaler appliance monitors the metrics collected from the VMs and triggers scale-up and scale-down events whenever the metrics breach the configured threshold for the specified period. As part of the scale-up trigger, the NetScaler AutoScale engine sends an API request to CloudPlatform to deploy a new VM. After the virtual machine is deployed, the AutoScale engine binds the service representing the VM (IP address and port) to the service group and, after the configured quiet time, starts forwarding load balanced traffic to the new virtual machine. Likewise, as part of the scale-down trigger, the NetScaler AutoScale engine selects a VM, stops forwarding new requests to that

instance, and waits for the configured quiet time (to allow for the processing of current requests to complete) before it sends an API request to CloudPlatform to destroy the chosen instance.

In this way, the NetScaler appliance monitors the application and triggers scale-up and scale-down events on the basis of application load and/or performance.

Supported Environment

Sep 30, 2013

AutoScale is supported in the following environment:

- Citrix CloudPlatform 3.0.5.
- Citrix NetScaler MPX/SDX/virtual appliance running Citrix NetScaler release 10.e and later.
- SNMP v1/v2.

Prerequisites

Sep 06, 2013

Before you set up AutoScale, do the following:

- Make sure that CloudPlatform is reachable from the NetScaler appliance. You can do so by logging on to the NetScaler appliance and sending ping requests to the CloudPlatform server's IP address.
- Make sure that the network service offering used in CloudPlatform includes the NetScaler appliance as an external load balancing device.
- Use a CloudPlatform and NetScaler release that supports AutoScale. For information about NetScaler releases that support AutoScale, see "Supported Environment."

If you have to troubleshoot an AutoScale setup, you also have to know the prerequisites for setting up AutoScale in CloudPlatform. See the "Prerequisites" section of "Configuring AutoScale" in the *Citrix CloudPlatform 3.0.5 (powered by Apache CloudStack) Administrator's Guide*, at http://support.citrix.com/article/CTX134823.

NetScaler Configuration Details

Mar 19, 2012

The following table describes the AutoScale configuration commands that are used by Citrix CloudPlatform to configure a NetScaler appliance.

Table 1. NetScaler Configuration for AutoScale

AutoScale configuration command(s)	Description
add lb vserver Cloud-VirtualServer-192.0.2.116-22 TCP 192.0.2.116 22 -persistenceType NONE -lbMethod ROUNDROBIN -cltTimeout 9000 -minAutoscaleMembers 2 -maxAutoscaleMembers 5	Creates a load balancing virtual server to evenly distribute the load on the application instances (ROUND-ROBIN method). The virtual server also specifies the limits for the number of instances to which the application can scale up or down (maxAutoscaleMembers and minAutoscaleMembers, respectively).
add serviceGroup Clouda35a6b6b76614006b97476e841b80f79 TCP -maxClient 0 -maxReq 0 -cip DISABLED -usip NO -useproxyport YES -cltTimeout 9000 -svrTimeout 9000 -CKA NO -TCPB NO -CMP NO -autoScale POLICY -memberPort 22 bind lb vserver Cloud-VirtualServer-192.0.2.116-22 Clouda35a6b6b76614006b97476e841b80f79	Creates an AutoScale service group for the application instances, with the service group's autoScale parameter set to POLICY. Also specifies the port on which the service group members must receive traffic. The second command binds the service group to the load balancing virtual server.
add server autoscale-internal_server_Clouda35a6b6b76614006b97476e841b80f79 autoscale-internal_server_Clouda35a6b6b76614006b97476e841b80f79 bind serviceGroup Clouda35a6b6b76614006b97476e841b80f79 autoscale-internal_server_Clouda35a6b6b76614006b97476e841b80f79 22	Creates a server entry to represent the application instances. Binds the server entry to the service group.
add lb metricTable Cloud-MTbl-192.0.2.116-22 bind lb metricTable Cloud-MTbl-192.0.2.116-22 Linux_User_CPU_-_percentage 1.3.6.1.4.1.2021.11.9.0	Configures a new SNMP monitor to retrieve the specified

AutoScale configuration command(s)	Description
add lb monitor Cloud-Mon-192.0.2.116-22 LOAD -interval 24 -destPort 161 -snmpCommunity public -metricTable Cloud-MTbl-192.0.2.116-22 bind lb monitor Cloud-Mon-192.0.2.116-22 -metric Linux_User_CPU_-_percentage -metricThreshold 2147483647 bind serviceGroup Clouda35a6b6b76614006b97476e841b80f79 -monitorName Cloud-Mon-192.0.2.116-22 -passive	metrics.
add autoscale profile Cloud-AutoScale-Profile-192.0.2.116-22 -type CLOUDSTACK -url "http://10.102.31.107:8080/client/api" -apiKey t0fEWPtk_ncQYbofjAm1jjlgGTR7UNZrkZ3sdEpLREBNzBPLSNpNz8qNSbc439xNtYnEYdWn_MsUC_CUazalKg -sharedSecret -PrE5h3DP7swHAN12TGBlX-xSTRLHzob91l6O0VO1FMxvE1UOl7uoD6_Z0bkkLaVtK5Y10oBkTzgbTwp3u5lCQ	Creates an AutoScale profile to specify the details required by NetScaler for making API requests to CloudPlatform (URL, API key, and shared secret).
add autoscale action Cloud-AutoScale-ScaleUpAction-192.0.2.116-22 -type SCALE_UP -profileName Cloud-AutoScale-Profile-192.0.2.116-22 -parameters "command=deployVirtualMachine&zoneid=2ab23590-78cb-4106-8d85-4412a2f2435f&serviceofferingid=b9503e47-0d8f-4c89-a88d-04d8b17fe8e9&templateid=1a4a5084-208c-47a8-9c16-d582550cf759&displayname=AutoScale-LB-lb&networkids=a3c97129-b729-4c72-994f-7b918f20ce4d&lbruleid=f96b7f3b-19ec-4123-891c-604f05b032b3" -quietTime 90 -vServer Cloud-VirtualServer-192.0.2.116-22	Creates a scale-up action, which enables the NetScaler appliance to add virtual machines (instances) to the application fleet.
add autoscale action Cloud-AutoScale-ScaleDownAction-192.0.2.116-22 -type SCALE_DOWN -profileName Cloud-AutoScale-Profile-192.0.2.116-22 -parameters "command=destroyVirtualMachine&lbruleid=f96b7f3b-19ec-4123-891c-604f05b032b3" -vmDestroyGracePeriod 30 -quietTime 90 -vServer Cloud-VirtualServer-192.0.2.116-22	Creates a scale-down action, which enables the NetScaler appliance to remove virtual machines (instances) from the application fleet.
add autoscale policy Cloud-AutoScale-Policy-Min-192.0.2.116-22 -rule "SYS.VSERVER(\"Cloud-VirtualServer-192.0.2.116-22\").ACTIVESERVICES.LT(SYS.VSERVER(\"Cloud-VirtualServer-192.0.2.116-22\").MINAUTOSCALEMEMBERS)" -action Cloud-AutoScale-ScaleUpAction-192.0.2.116-22	Creates an AutoScale policy to initially create the specified minimum number of VMs and, later, to ensure that the number of VMs in the fleet does not fall below the required minimum.
add autoscale policy Cloud-AutoScale-Policy-Max-192.0.2.116-22 -rule "SYS.VSERVER(\"Cloud-VirtualServer-192.0.2.116-22\").ACTIVESERVICES.GT(SYS.VSERVER(\"Cloud-VirtualServer-192.0.2.116-22\").MAXAUTOSCALEMEMBERS)" -action Cloud-AutoScale-ScaleDownAction-192.0.2.116-22	Creates an AutoScale policy to prevent the number of VMs in the fleet from exceeding the specified maximum.
add autoscale policy Cloud-AutoScale-Policy-192.0.2.116-22-35 -rule "SYS.VSERVER(\"Cloud-VirtualServer-192.0.2.116-22\").ACTIVESERVICES.LT(SYS.VSERVER(\"Cloud-VirtualServer-192.0.2.116-22\").MAXAUTOSCALEMEMBERS) && (SYS.VSERVER(\"Cloud-VirtualServer-192.0.2.116-22\").SNMP_TABLE(0).AVERAGE_VALUE.GT(90))" -action Cloud-AutoScale-ScaleUpAction-192.0.2.116-22	Creates an AutoScale policy to evaluate the metrics that are collected and trigger a

AutoScale configuration command(s)	Description
	scale-up action when the metric value breaches the threshold specified for the scale-up policy.
add autoscale policy Cloud-AutoScale-Policy-192.0.2.116-22-36 -rule "SYS.VSERVER(\"Cloud-VirtualServer-192.0.2.116-22\").ACTIVESERVICES.GT(SYS.VSERVER(\"Cloud-VirtualServer-192.0.2.116-22\").MINAUTOSCALEMEMBERS) && (SYS.VSERVER(\"Cloud-VirtualServer-192.0.2.116-22\").SNMP_TABLE(0).AVERAGE_VALUE.LT(30))" -action Cloud-AutoScale-ScaleDownAction-192.0.2.116-22	Creates an AutoScale policy to evaluate the collected metrics and trigger a scale-down action when the metric value breaches the threshold specified by the scale-down policy.
add ns timer Cloud-AutoScale-Timer-192.0.2.116-22 -interval 30 bind ns timer Cloud-AutoScale-Timer-192.0.2.116-22 -policyName Cloud-AutoScale-Policy-Min-192.0.2.116-22 -priority 1 -gotoPriorityExpression END -sampleSize 1 -threshold 1 bind ns timer Cloud-AutoScale-Timer-192.0.2.116-22 -policyName Cloud-AutoScale-Policy-Max-192.0.2.116-22 -priority 2 -gotoPriorityExpression END -sampleSize 1 -threshold 1 bind ns timer Cloud-AutoScale-Timer-192.0.2.116-22 -policyName Cloud-AutoScale-Policy-192.0.2.116-22-35 -priority 3 -gotoPriorityExpression END -sampleSize 2 -threshold 2 bind ns timer Cloud-AutoScale-Timer-192.0.2.116-22 -policyName Cloud-AutoScale-Policy-192.0.2.116-22-36 -priority 4 -gotoPriorityExpression END -sampleSize 2 -threshold 2	Creates a timer that enables evaluation of the AutoScale policies at the configured sampling intervals.

Troubleshooting

Sep 06, 2013

Before you attempt to resolve an AutoScale issue, make sure that the prerequisites have been adhered to, on both the CloudPlatform server and the NetScaler appliance, as described in "Prerequisites." If that does not resolve the issue, your problem could be one of the following.

The AutoScale configuration was successfully configured in CloudPlatform. Yet, the minimum number of VMs has not been created.

- Recommend that the CloudPlatform user deploy one VM manually in the network before configuring AutoScale. Ask the user to remove the AutoScale configuration from the NetScaler appliance or the load balancer from the network, manually deploy one VM (preferably using the template created for the AutoScale configuration), and then create the AutoScale configuration.
- Verify that the CloudPlatform user has configured the VM template in such a way that the VMs that are created from the template can accept traffic without manual intervention. If a provisioned VM cannot accept traffic automatically, the metric remains above the threshold, and the AutoScale configuration continues to provision additional VMs, as designed. To remedy the issue, disable AutoScale from CloudPlatform, fix the template, and then enable AutoScale.
- Verify that the CloudPlatform user has not exceeded the limit for the number of VMs imposed by the user's account.
- Verify that the CloudPlatform server is up and is reachable from the NetScaler appliance.
- Verify that the CloudPlatform log file, management-server.log, has reported the successful creation of the AutoScale configuration in CloudPlatform.
- Verify that the scale-up policy that is responsible for initial scale up (the policy name is prefixed with Cloud-AutoScale-Policy-Min) is receiving hits.

The AutoScale configuration is rapidly spawning a large number of VMs

- Verify that the CloudPlatform user has configured the VM template in such a way that the VMs that are created from the template can accept traffic without manual intervention. If a provisioned VM cannot accept traffic automatically, the metric remains above the threshold, and the AutoScale configuration continues to provision additional VMs, as designed. To remedy the issue, disable AutoScale from CloudPlatform, fix the template, and then enable AutoScale.
- Verify that the quiet time that the CloudPlatform user has configured in the AutoScale configuration is sufficient to ensure even traffic distribution to all the VMs, including the new VM. If the quiet time is too low, and traffic distribution has not stabilized, the metrics might remain above the threshold, and additional VMs might be spawned.

When I ran the top command on my VM, I noticed that the CPU usage on my VM had breached the threshold that was configured for the scale-up action in AutoScale. Yet, the application is not scaling up.

- Verify that the CloudPlatform user has installed an SNMP agent in the VM template, and that the SNMP agent is up and running on every VM.
- Verify that the CloudPlatform user has not exceeded the limit for the number of VMs imposed by the user's account.
- Verify that the CloudPlatform user has correctly configured the SNMP parameters to collect metrics from the VM (for example, the community string and the port).
- Verify that the scale-up or scale-down policy is receiving hits.
- Verify that the CloudPlatform server is up, and that the CloudPlatform server is reachable from the NetScaler appliance.

One or more additional VMs have been created, but they are not accepting traffic (that is, VMs have been created, but the average value of the metrics is still above the threshold)

- Verify that the user has configured the templates in such a way that the VMs created from the templates can start serving traffic without any manual intervention.
- Verify that the service is running on the VMs, on the configured member port.
- Send a ping request to the gateway (virtual router), from the VM that is not accepting traffic.

The AutoScale configuration has been deleted, but the VMs continue to exist

- The VMs might not be deleted immediately after the AutoScale configuration is deleted. Wait for about 5 minutes after you have deleted the AutoScale configuration, and then check again.
- If the destruction of VMs has not commenced after 5 minutes, you might have to delete the VMs manually.

CloudBridge Connector

Oct 18, 2016

Note: The current NetScaler 1000V release does not support this feature.

The CloudBridge Connector feature of the Citrix NetScaler appliance connects enterprise datacenters to external clouds and hosting environments, making the cloud a secure extension of your enterprise network. Cloud-hosted applications appear as though they are running on one contiguous enterprise network. With Citrix CloudBridge Connector, you can augment your datacenters with the capacity and efficiency available from cloud providers.

The CloudBridge Connector enables you to move your applications to the cloud to reduce costs and increase reliability.

In addition to using CloudBridge Connector between a datacenter and a cloud, you can use it to connect two datacenters for a high-capacity secure and accelerated link.

Understanding CloudBridge Connector

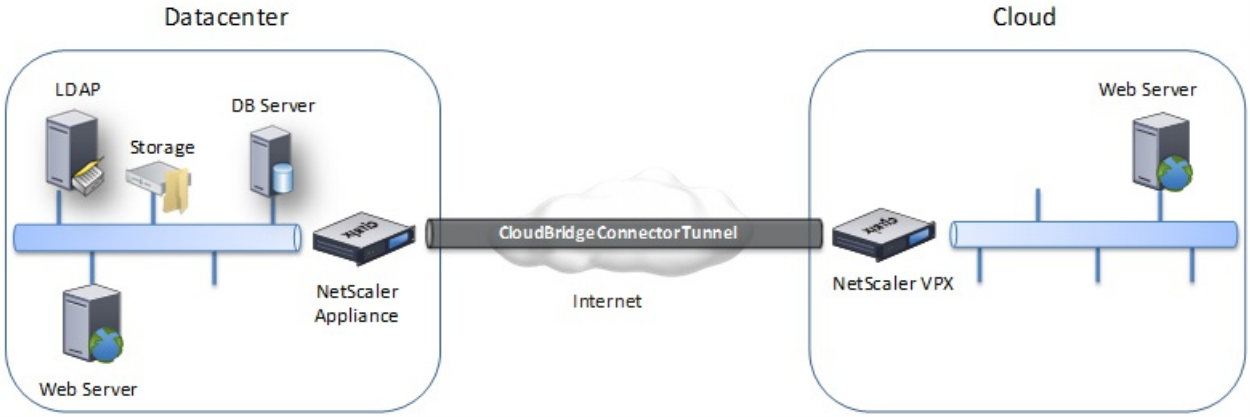
Updated: 2014-04-14

To implement the Citrix CloudBridge Connector solution, you connect a datacenter to another datacenter or an external cloud by setting up a tunnel called the CloudBridge Connector tunnel.

To connect a datacenter to another datacenter, you set up a CloudBridge Connector tunnel between two NetScaler appliances, one in each datacenter.

To connect a datacenter to an external cloud (for example, Amazon AWS cloud), you set up a CloudBridge Connector tunnel between a NetScaler appliance in the datacenter and a virtual appliance (VPX) that resides in the Cloud. The remote end point can be a CloudBridge Connector or a NetScaler VPX with platinum license.

The following illustration shows a CloudBridge Connector tunnel set up between a datacenter and an external cloud.



The appliances between which a CloudBridge Connector tunnel is set up are called the *end points* or *peers* of the CloudBridge Connector tunnel.

A CloudBridge Connector tunnel uses the following protocols:

- Generic Routing Encapsulation (GRE) protocol
- Open-standard IPSec Protocol suite, in transport mode

The GRE protocol provides a mechanism for encapsulating packets, from a wide variety of network protocols, to be forwarded over another protocol. GRE is used to:

- Connect networks running non-IP and non-routable protocols.
- Bridge across a wide area network (WAN).
- Create a transport tunnel for any type of traffic that needs to be sent unchanged across a different network.

The GRE protocol encapsulates packets by adding a GRE header and a GRE IP header to the packets.

The Internet Protocol security (IPSec) protocol suite secures communication between peers in the CloudBridge Connector tunnel.

In a CloudBridge Connector tunnel, IPSec ensures:

- Data integrity
- Data origin authentication
- Data confidentiality (encryption)
- Protection against replay attacks

IPSec uses the transport mode in which the GRE encapsulated packet is encrypted. The encryption is done by the Encapsulating Security Payload (ESP) protocol. The ESP protocol ensures the integrity of the packet by using a HMAC hash function, and ensures confidentiality by using an encryption algorithm. After the packet is encrypted and the HMAC is calculated, an ESP header is generated. The ESP header is inserted after the GRE IP header and, an ESP trailer is inserted at the end of the encrypted payload.

Peers in the CloudBridge Connector tunnel use the Internet Key Exchange version (IKE) protocol (part of the IPSec protocol suite) to negotiate secure communication, as follows:

- The two peers mutually authenticate with each other, using one of the following authentication methods:
  - **Pre-shared key authentication**. A text string called a pre-shared key is manually configured on each peer. The pre-shared keys of the peers are matched against each other for authentication. Therefore, for the authentication to be successful, you must configure the same pre-shared key on each of the peers.
  - **Digital certificates authentication**. The initiator (sender) peer signs message interchange data by using its private key, and the other receiver peer uses the sender's public key to verify the signature. Typically, the public key is exchanged in messages containing an X.509v3 certificate. This certificate provides a level of assurance that a peer's identity as represented in the certificate is associated with a particular public key.
- The peers then negotiate to reach agreement on:
  - An encryption algorithm.
  - Cryptographic keys for encrypting data in one peer and decrypting the data in the other.

This agreement upon the security protocol, encryption algorithm and cryptographic keys is called a Security Association (SA). SAs are one-way (simplex). For example, when two peers, CB1 and CB2, are communicating through a Connector tunnel, CB1 has two Security Associations. One SA is used for processing out-bound packets, and the other SA is used for processing inbound packets.

SAs expire after a specified length of time, which is called the *lifetime*. The two peers use the Internet Key Exchange (IKE) protocol (part of the IPSec protocol suite) to negotiate new cryptographic keys and establish new SAs. The purpose of the limited lifetime is to prevent attackers from cracking a key.

The following table lists some IPSec propeties supported by a NetScaler appliance:

IPSec Properties	Types Supported
IKE Versions	• V1 • V2
IKE Authentication Methods	• Pre-shared key authentication • Digital certificates authentication
Encryption Algorithm	• AES • 3DES
Hash Algorithm	• HMAC SHA1 • HMAC SHA256 • HMAC SHA384 • HMAC SHA512 • HMAC MD5

Monitoring CloudBridge Connector Tunnels

Oct 12, 2016

You can display the statistics for monitoring the performance of a CloudBridge Connector tunnel. To display CloudBridge Connector tunnel statistics on a NetScaler appliance, use the NetScaler GUI or the NetScaler command line.

The following table lists the statistical counters available for monitoring CloudBridge Connector tunnels on a NetScaler appliance.

Statistical counter	**Specifies**
Bytes Received	Total number of bytes received by the NetScaler appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.
Bytes Sent	Total number of bytes sent by the NetScaler appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.
Packets Received	Total number of packets received by the NetScaler appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.
Packets Sent	Total number of packets sent by the NetScaler appliance through all the configured CloudBridge Connector tunnels since the appliance was last started.
Bytes Received Rate	Number of bytes per second received by the NetScaler appliance through all the configured CloudBridge Connector tunnels.
Bytes Sent Rate	Number of bytes per second sent by the NetScaler appliance through all the configured CloudBridge Connector tunnels
Packets Received Rate	Number of bytes per second received by the NetScaler appliance through all the configured CloudBridge Connector tunnels
Packets Sent Rate	Number of bytes per second received by the NetScaler appliance through all the configured CloudBridge Connector tunnels

All these counters are reset to 0 when the NetScaler appliance is restarted. They do not increment during the following phases:

- Internet Key Exchange (IKE) authentication (pre-shared key) phase on any configured CloudBridge Connector tunnel.
- IKE Security Association (SA) establishment phase on any configured CloudBridge Connector tunnel.

To display CloudBridge Connector tunnel statistics by using the NetScaler command line

At the command prompt, type:

- **stat ipsec counters**

To display CloudBridge Connector tunnel statistics by using the NetScaler GUI

1. Access the NetScaler GUI by using a web browser to connect to the IP address of the NetScaler appliance.
2. On the **Configuation** tab, navigate to **System** > **CloudBridge Connector**.
3. On the CloudBridge Connector page, click **Create/Monitor CloudBridge Connector**. The **IPSec Bytes** and **IPSec Packets** charts display the bytes received rate, bytes sent rate, packets received rate, and packets sent rate of all the CloudBridge Connector tunnels configured on the NetScaler appliance.

Sample Output COPY

```
> stat ipsec counters

Secure tunnel(s) summary

                Rate (/s)       Total

Bytes Received    0    2811248

Bytes Sent        0    157460630

Packets Received    0    56787

Packets Sent      0    200910

Done

>
```

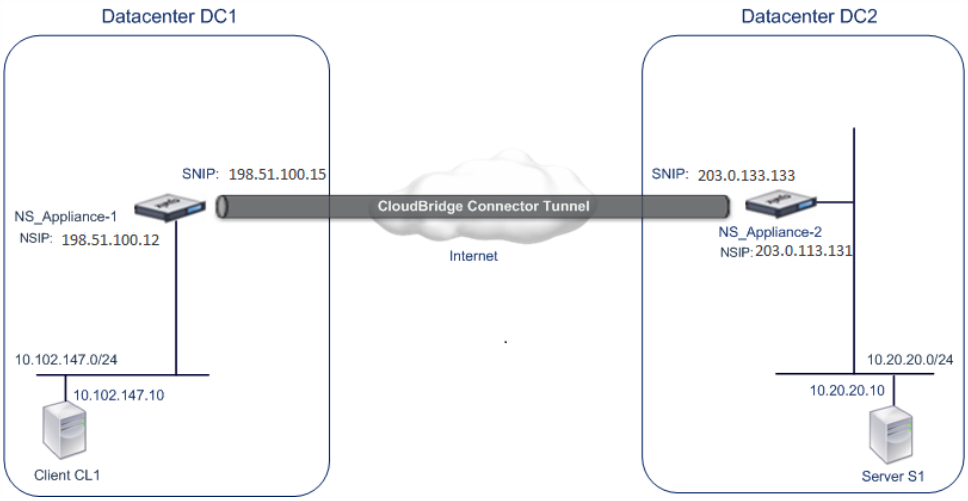
Configuring a CloudBridge Connector Tunnel between two Datacenters

Oct 12, 2016

You can configure a CloudBridge Connector tunnel between two different datacenters to extend your network without reconfiguring it, and leverage the capabilities of the two datacenters. A CloudBridge Connector tunnel between the two geographically separated datacenters enables you to implement redundancy and safeguard your setup from failure. The CloudBridge Connector tunnel helps achieve optimal utilization of infrastructure and resources across datacenters. The applications available across the two datacenters appear as local to the user.

To connect a datacenter to another datacenter, you set up a CloudBridge Connector tunnel between a NetScaler appliance in one datacenter and a NetScaler appliance in the other datacenter.

As an illustration of CloudBridge Connector tunnel between datacenters, consider an example in which a CloudBridge Connector tunnel is set up between NetScaler appliance NS_Appliance-1 in datacenter DC1 and NetScaler appliance NS_Appliance-2 in datacenter DC2.



Both NS_Appliance-1 and NS_Appliance-2 function in L2 and L3 mode. They enable communication between private networks in datacenters DC1 and DC2. In L3 mode, NS_Appliance-1 and NS_Appliance-2 enable communication between client CL1 in datacenter DC1 and server S1 in the datacenter DC2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

Because client CL1 and server S1 are on different private networks, L3 mode is enabled on NS_Appliance-1 and NS_Appliance-2, and routes are updated as follows:

- CL1 has a route to NS_Appliance-1 for reaching S1.
- NS_Appliance-1 has a route to NS_Appliance-2 for reaching S1.
- S1 has a route to NS_Appliance-2 for reaching CL1.
- NS_Appliance-2 has a route to NS_Appliance-1 for reaching CL1.

The following table lists the settings on NetScaler appliance NS_Appliance-1 in datacenter DC1.

Entity	Name	Details
The NSIP address		198.51.100.12

SNIP address		198.51.100.15
CloudBridge Connector tunnel	Cloud_Connector_DC1-DC2	• Local endpoint IP address of the CloudBridge Connector tunnel: 198.51.100.15 • Remote endpoint IP address of the CloudBridge Connector tunnel: 203.0.113.133 **GRE Tunnel Details** • Name = Cloud_Connector_DC1-DC2 **IPSec Profile Details** • Name = Cloud_Connector_DC1-DC2 • Encryption algorithm = AES • Hash algorithm = HMAC SHA1

The following table lists the settings on NetScaler appliance NS_Appliance-2 in datacenter DC2.

Entity	Name	Details
The NSIP address		203.0.113.131
SNIP address		203.0.113.133
CloudBridge Connector tunnel	Cloud_Connector_DC1-DC2	• Local endpoint IP address of the CloudBridge Connector tunnel: 203.0.113.133 • Remote endpoint IP address of the CloudBridge Connector tunnel: 198.51.100.15 **GRE Tunnel Details** • Name = Cloud_Connector_DC1-DC2 **IPSec Profile Details** • Name = Cloud_Connector_DC1-DC2 • Encryption algorithm = AES • Hash algorithm = HMAC SHA1

Points to Consider for Configuring CloudBridge Connector Tunnel

Before setting up a CloudBridge Connector tunnel, verify that the following tasks have been completed:

1. Deploy and set up a NetScaler appliance in each of the two datacenters.
2. Make sure that the CloudBridge Connector tunnel end-point IP addresses are accessible to each other.

Configuration Procedure

To set up a CloudBridge Connector tunnel between a NetScaler appliance that resides in one datacenter and another NetScaler appliance that resides in the other datacenter, use the configuration utility or the command line interface of one of the NetScaler appliances.

When you use the configuration utility, the CloudBridge Connector tunnel configuration created on the first NetScaler appliance is automatically pushed to the other endpoint (the other NetScaler appliance) of the CloudBridge Connector tunnel. Therefore, you do not have to access the configuration utility of the other NetScaler appliance to create the corresponding CloudBridge Connector tunnel configuration on it.

The CloudBridge Connector tunnel configuration on each of the NetScaler appliances consists of the following entities:

- **IPSec profile**—An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and PSK, to be used by the IPSec protocol in the CloudBridge Connector tunnel.
- **GRE tunnel**—An IP tunnel specifies the local IP address (a public SNIP address configured on the local NetScaler appliance), remote IP address (a public SNIP address configured on the remote NetScaler appliance), protocol (GRE) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity.
- **Create a PBR rule and associate the IP tunnel with it**—A PBR entity specifies a set of conditions and an IP tunnel entity. The source IP address range and the destination IP range are the conditions for the PBR entity. You must set the source IP address range and the destination IP address range to specify the subnet whose traffic is to traverse the CloudBridge Connector tunnel. For example, consider a request packet that originates from a client on the subnet in the first datacenter and is destined to a server on the subnet in the second datacenter. If this packet matches the source and destination IP address range of the PBR entity on the NetScaler appliance in the first datacenter, it is sent across the CloudBridge Connector tunnel associated with the PBR entity.

To create an IPSEC profile by using the command line interface

At the command prompt, type:

- **add ipsec profile** <name> [-**ikeVersion** (V1 | V2)] [-**encAlgo** (AES | 3DES) ...] [-**hashAlgo** <hashAlgo> ...] [-**lifetime** <positive_integer>] (-**psk** | (-**publickey** <string> -**privatekey** <string> -**peerPublicKey** <string>)) [-**livenessCheckInterval** <positive_integer>] [-**replayWindowSize** <positive_integer>] [-**ikeRetryInterval** <positive_integer>] [-**retransmissiontime** <positive_integer>]
- **show ipsec profile** <name>

To create an IP tunnel and bind the IPSEC profile to it by using the command line interface

At the command prompt, type:

- **add ipTunnel** <name> <remote><remoteSubnetMask> <local> [-**protocol** <protocol>] [-**ipsecProfileName** <string>]
- **show ipTunnel** <name>

To create a PBR rule and bind the IPSEC tunnel to it by using the command line interface

At the command prompt, type:

- **add ns pbr** <pbr_name> ALLOW -**srcIP** = <local_subnet_range> -**destIP** = <remote_subnet_range> -**ipTunnel** <tunnel_name>
- **apply ns pbrs**
- **show ns pbr** <pbr_name>

Sample Configuration COPY

```
> add ipsec profile Cloud_Connector_DC1-DC2  -encAlgo AES -hashAlgo HMAC_SHA1

Done

> add ipTunnel Cloud_Connector_DC1-DC2 203.0.113.133 255.255.255.255 198.51.100.15 -protocol GRE -ipsecProfileName Cloud_Co

Done

> add ns pbr PBR-DC1-DC2 ALLOW -srcIP 198.51.100.15 -destIP 203.0.113.133 ipTunnel Cloud_Connector_DC1-DC2

Done

> apply ns pbrs

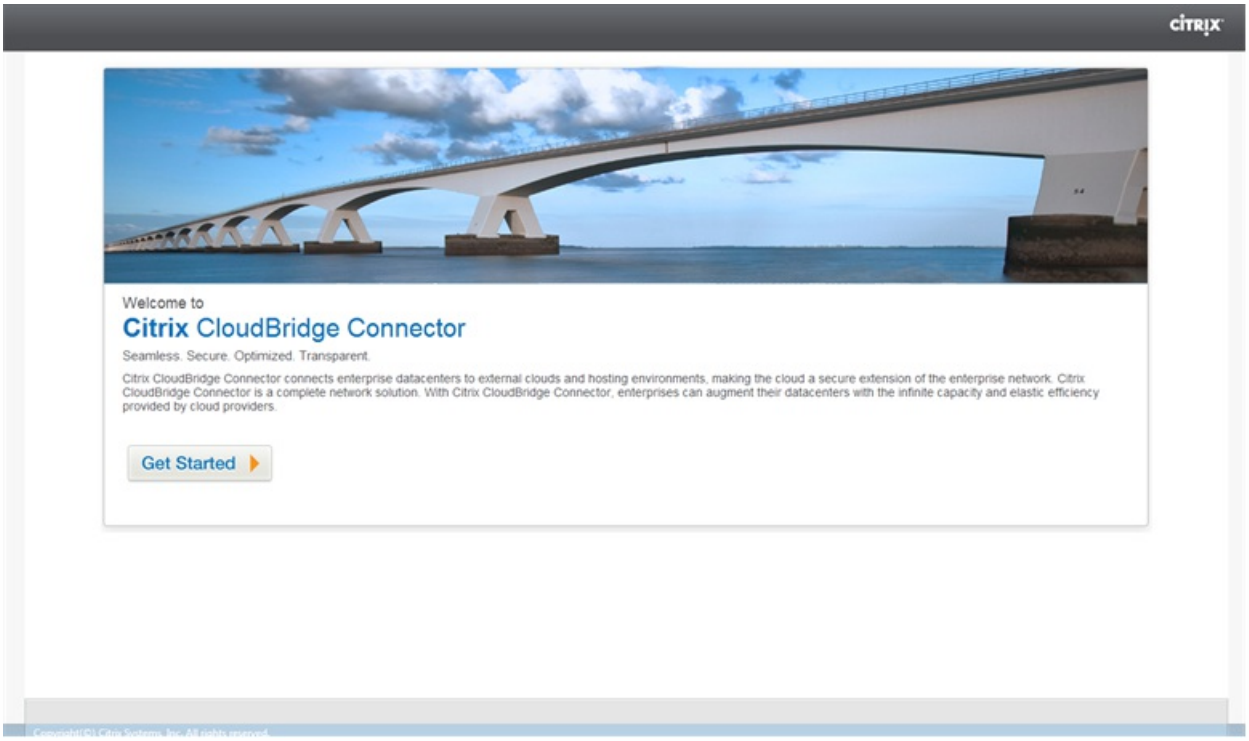
Done
```

To configure a CloudBridge Connector tunnel in a NetScaler appliance by using the configuration utility

1. Type the NSIP address of a NetScaler appliance in the address line of a web browser.
2. Log on to the configuration utility of the NetScaler appliance by using your account credentials for the appliance.
3. Navigate to **System** > **CloudBridge Connector**.
4. In the right pane, under **Getting Started**, click **Create/Monitor CloudBridge**.

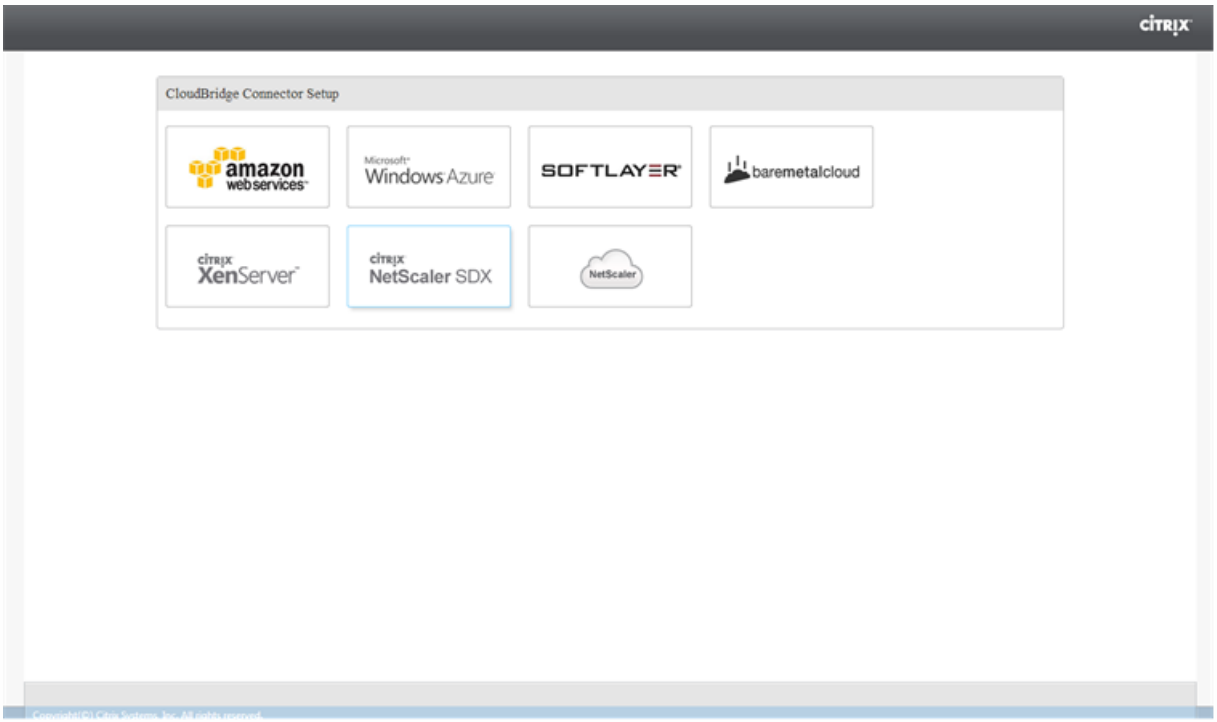
   The first time you configure a CloudBridge Connector tunnel on the appliance, a **Welcome** screen appears.

5. On the **Welcome** screen click **Get Started**.



Note: If you already have a CloudBridge Connector tunnel configured on the NetScaler appliance, the Welcome screen does not appear, so you do not click Get Started.

6. In the **CloudBridge Connector Setup** pane, click **NetScaler**.



7. In the NetScaler pane, provide your account credentials for the remote NetScaler appliance. Click **Continue**.
8. In the **CloudBridge Connector Setting** pane, set the following parameter:
   - **CloudBridge Connector Name**— Name for the CloudBridge Connector configuration on the local appliance. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the

CloudBridge Connector configuration is created.

9. Under **Local Setting**, set the following parameter:
   - **Subnet IP**—IP address of the local endpoint of the CloudBridge Connector tunnel.
10. Under **Remote Setting**, set the following parameter:
    - **Subnet IP**—IP address of the peer endpoint of the CloudBridge Connector tunnel.
11. Under **PBR** Setting, set the following parameters:
    - **Operation**—Either the equals (=) or does not equal (!=) logical operator.
    - **Source IP Low***—Lowest source IP address to match against the source IP address of an outgoing IPv4 packet.
    - **Source IP High**—Highest source IP address to match against the source IP address of an outgoing IPv4 packet.
    - **Operation**—Either the equals (=) or does not equal (!=) logical operator.
    - Destination IP Low*—Lowest destination IP address to match against the destination IP address of an outgoing IPv4 packet.
    - **Destination IP High**—Highest destination IP address to match against the destination IP address of an outgoing IPv4 packet.
12. (Optional) Under **Security Settings**, set the following IPSec protocol parameters for the CloudBridge Connector tunnel:
    - **Encryption Algorithm**—Encryption algorithm to be used by the IPSec protocol in the CloudBridge tunnel.
    - **Hash Algorithm**—Hash algorithm to be used by the IPSec protocol in the CloudBridge tunnel.
    - **Key**—Select one of the following IPSec authentication methods to be used by the two peers to mutually authenticate.
      - **Auto Generate Key**—Authentication based on a text string, called a pre-shared key (PSK), generated automatically by the local appliance. The PSKs keys of the peers are matched against each other for authentication.
      - **Specific Key**—Authentication based on a manually entered PSK. The PSKs of the peers are matched against each other for authentication.
        - Pre Shared Security Key—The text string entered for pre-shared key based authentication.
      - **Upload Certificates**—Authentication based on digital certificates.
        - **Public Key**—A local digital certificate to be used to authenticate the local NetScaler appliance to the peer before establishing IPSec security associations. The same certificate should be present and set for the Peer Public Key parameter in the peer.
        - **Private Key**—Private key of the local digital certificate.
        - **Peer Public Key**—Digital certificate of the peer. Used to authenticate the peer to the local end point before establishing IPSec security associations. The same certificate should be present and set for the Public key parameter in the peer.
13. Click **Done**.

The new CloudBridge Connector tunnel configuration on both the NetScaler appliances appears on the Home tab of the respective configuration utility. The current status of the CloudBridge connector tunnel is indicated in the Configured CloudBridge Connectors pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

Monitoring the CloudBridge Connector Tunnel

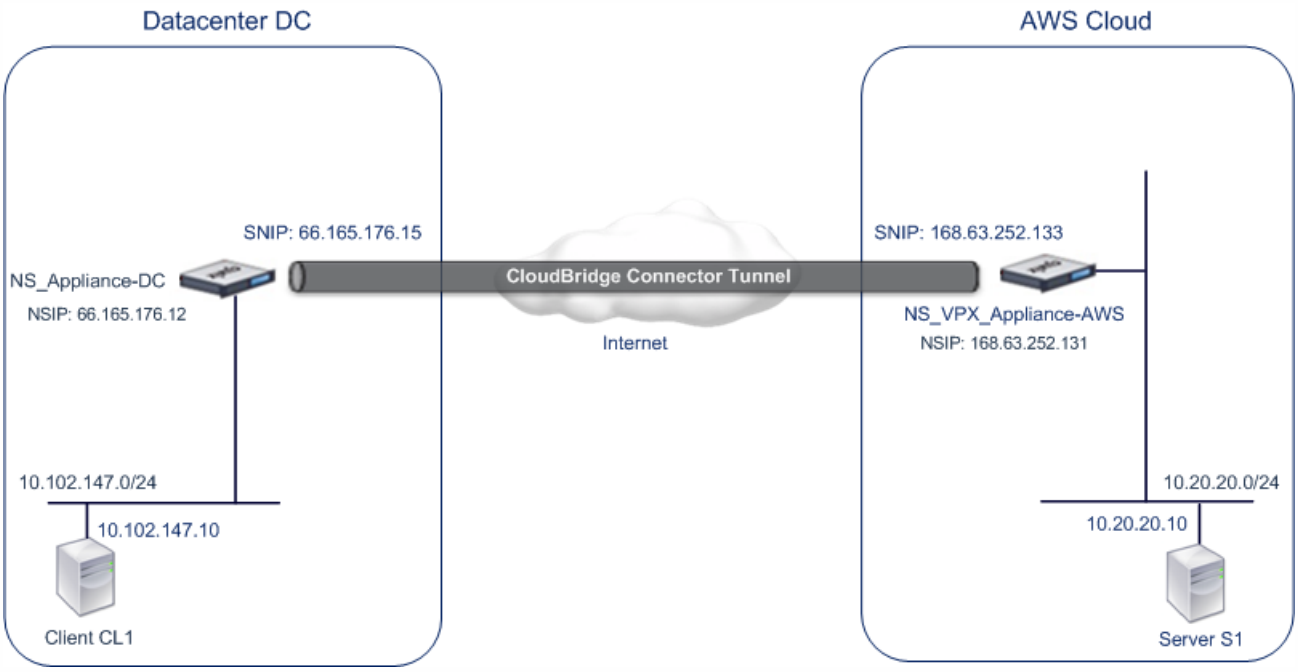
You can monitor the performance of CloudBridge Connector tunnels on a NetScaler appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a NetScaler appliance, see Monitoring CloudBridge Connector Tunnels.

Configuring CloudBridge Connector between Datacenter and AWS Cloud

Oct 18, 2016

You can configure a CloudBridge Connector tunnel between a datacenter and AWS cloud to leverage the infrastructure and computing capabilities of the data center and the AWS cloud. With AWS, you can extend your network without initial capital investment or the cost of maintaining the extended network infrastructure. You can scale your infrastructure up or down, as required. For example, you can lease more server capabilities when the demand increases.
To connect a datacenter to AWS cloud, you set up a CloudBridge Connector tunnel between a NetScaler appliance that resides in the datacenter and a NetScaler virtual appliance (VPX) that resides in AWS cloud.

As an illustration of a CloudBridge Connector tunnel between a datacenter and Amazon AWS cloud, consider an example in which a CloudBridge Connector tunnel is set up between NetScaler appliance NS_Appliance-DC, in datacenter DC, and NetScaler virtual appliance (VPX) NS_VPX_Appliance-AWS.



Both NS_Appliance-DC and NS_VPX_Appliance-AWS function in L3 mode. They enable communication between private networks in datacenter DC and the AWS cloud. NS_Appliance-DC and NS_VPX_Appliance-AWS enable communication between client CL1 in datacenter DC and server S1 in the AWS cloud through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

Note: AWS does not support L2 mode, hence it is necessary to have only L3 mode enabled on both the endpoints.
For proper communication between CL1 and S1, L3 mode is enabled on NS_Appliance-DC and NS_VPX_Appliance-AWS and routes are updated as such:

- CL1 have a route to NS_Appliance-DC for reaching S1.
- NS_Appliance-DC have a route to NS_VPX_Appliance-AWS for reaching S1.
- S1 should have a route to NS_VPX_Appliance-AWS for reaching CL1.
- NS_VPX_Appliance-AWS have a route to NS_Appliance-DC for reaching CL1.

The following table lists the settings on NetScaler appliance NS_Appliance-DC in datacenter DC.

Entity	Name	Details
The NSIP address		66.165.176.12
SNIP address		66.165.176.15
CloudBridge Connector tunnel	CC_Tunnel_DC-AWS	• Local endpoint IP address of the CloudBridge Connector tunnel: 66.165.176.15 • Remote endpoint IP address of the CloudBridge Connector tunnel: 168.63.252.133 **GRE Tunnel Details** • Name= CC_Tunnel_DC-AWS **IPSec Profile Details** • Name= CC_Tunnel_DC-AWS • Encryption algorithm= AES • Hash algorithm= HMAC SHA1

The following table lists the settings on NetScaler VPX NS_VPX_Appliance-AWS on AWS cloud.

Entity	Name	Details
NSIP address		10.102.25.30
Public EIP address mapped to the NSIP address		168.63.252.131
SNIP address		10.102.29.30
Public EIP address mapped to the SNIP address		168.63.252.133
CloudBridge Connector tunnel	CC_Tunnel_DC-AWS	• Local endpoint IP address of the CloudBridge Connector tunnel: 168.63.252.133 • Remote endpoint IP address of the CloudBridge Connector tunnel: 66.165.176.15 **GRE Tunnel Details** • Name= CC_Tunnel_DC-AWS **IPSec Profile Details** • Name= CC_Tunnel_DC-AWS • Encryption algorithm= AES • Hash algorithm= HMAC SHA1

Prerequisites

Updated: 2015-06-01

Before setting up a CloudBridge Connector tunnel, verify that the following tasks have been completed:

1. Install, configure, and launch an instance of NetScaler Virtual appliance (VPX) on AWS cloud. For instructions on installing NetScaler VPX on AWS, see http://support.citrix.com/proddocs/topic/netscaler-vpx-10-5/nsvpx-aws-ns-vpxaws-con.html.

2. Deploy and configure a NetScaler physical appliance, or provisioning and configuring a NetScaler virtual appliance (VPX) on a virtualization platform in the datacenter.
   - For instructions on installing NetScaler vitrual appliances on Xenserver, see http://support.citrix.com/proddocs/topic/netscaler-vpx-10-5/ns-vpx-install-wrapper-con.html.
   - For instructions on installing NetScaler vitrual appliances on VMware ESX or ESXi, see http://support.citrix.com/proddocs/topic/netscaler-vpx-10-5/ns-vpx-install-on-esx-wrapper-con.html.
   - For instructions on installing NetScaler vitrual appliances on Microsoft Hyper-V, see http://support.citrix.com/proddocs/topic/netscaler-vpx-10-5/ns-vpx-install-on-msft-hyperv-wrapper-con.html.
3. Make sure that the CloudBridge Connector tunnel end-point IP addresses are accessible to each other.

NetScaler VPX License

After the initial instance launch, NetScaler VPX for AWS requires a license. If you are bringing your own license (BYOL), see the VPX Licensing Guide at: http://support.citrix.com/article/CTX122426.

You have to:
1. Use the licensing portal within MyCitrix to generate a valid license.
2. Upload the license to the instance.

If this is a **paid** marketplace instance, then you do not need to install a license. The correct feature set and performance will activate automatically.

Configuration Steps

To set up a CloudBridge Connector tunnel between a NetScaler appliance that resides in a datacenter and a NetScaler virtual appliance (VPX) that resides on the AWS cloud, use the configuration utility of the NetScaler appliance.

When you use the configuration utility, the CloudBridge Connector tunnel configuration created on the NetScaler appliance, is automatically pushed to the other endpoint or peer (the NetScaler VPX on AWS) of the CloudBridge Connector tunnel. Therefore, you do not have to access the configuration utility (GUI) of the NetScaler VPX on AWS to create the corresponding CloudBridge Connector tunnel configuration on it.

The CloudBridge Connector tunnel configuration on both peers (the NetScaler appliance that resides in the datacenter and the NetScaler virtual appliance (VPX) that resides on the AWS cloud) consists of the following entities:

- **IPSec profile**—An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and PSK, to be used by the IPSec protocol in both the peers of the CloudBridge Connector tunnel.
- **GRE tunnel**—An IP tunnel specifies a local IP address (a public SNIP address configured on the local peer), remote IP address (a public SNIP address configured on the remote peer), protocol (GRE) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity.
- **Create a PBR rule and associate the IP tunnel with it**—A PBR entity specifies a set of conditions and an IP tunnel entity. The source IP address range and the destination IP range are the conditions for the PBR entity. You must set the source IP address range and the destination IP address range to specify the subnet whose traffic is to traverse the

CloudBridge Connector tunnel. For example, consider a request packet that originates from a client on the subnet in the datacenter and is destined to a server on the subnet in the AWS cloud. If this packet matches the source and destination IP address range of the PBR entity on the NetScaler appliance in the datacenter, it is sent across the CloudBridge Connector tunnel associated with the PBR entity.

To create an IPSEC profile by using the command line interface

At the command prompt, type:

- **add ipsec profile** <name> [-**ikeVersion** (V1 | V2)] [-**encAlgo** (AES | 3DES) ...] [-**hashAlgo** <hashAlgo> ...] [-**lifetime** <positive_integer>] (-**psk** | (-**publickey** <string> -**privatekey** <string> -**peerPublicKey** <string>)) [-**livenessCheckInterval** <positive_integer>] [-**replayWindowSize** <positive_integer>] [-**ikeRetryInterval** <positive_integer>] [-**retransmissiontime** <positive_integer>]
- **show ipsec profile** <name>

To create an IP tunnel and bind the IPSEC profile to it by using the command line interface

At the command prompt, type:

- **add ipTunnel** <name> <remote><remoteSubnetMask> <local> [-**protocol** <protocol>] [-**ipsecProfileName** <string>]
- **show ipTunnel** <name>

To create a PBR rule and bind the IPSEC tunnel to it by using the command line interface

At the command prompt, type:

- **add ns pbr** <pbr_name> ALLOW -**srcIP** = <local_subnet_range> -**destIP** = <remote_subnet_range> -**ipTunnel** <tunnel_name>
- **apply ns pbrs**
- **show ns pbr <pbr_name>**

Sample Configuration COPY

```
> add ipsec profile CC_Tunnel_DC-AWS -encAlgo AES -hashAlgo HMAC_SHA1

Done

> add ipTunnel CC_Tunnel_DC-AWS 168.63.252.133 255.255.255.0 66.165.176.15 –protocol GRE -ipsecProfileName CC_Tunnel_DC-A

Done

> add ns pbr PBR-DC-AWS ALLOW –srcIP 66.165.176.15 –destIP 168.63.252.133 ipTunnel CC_Tunnel_DC-AWS

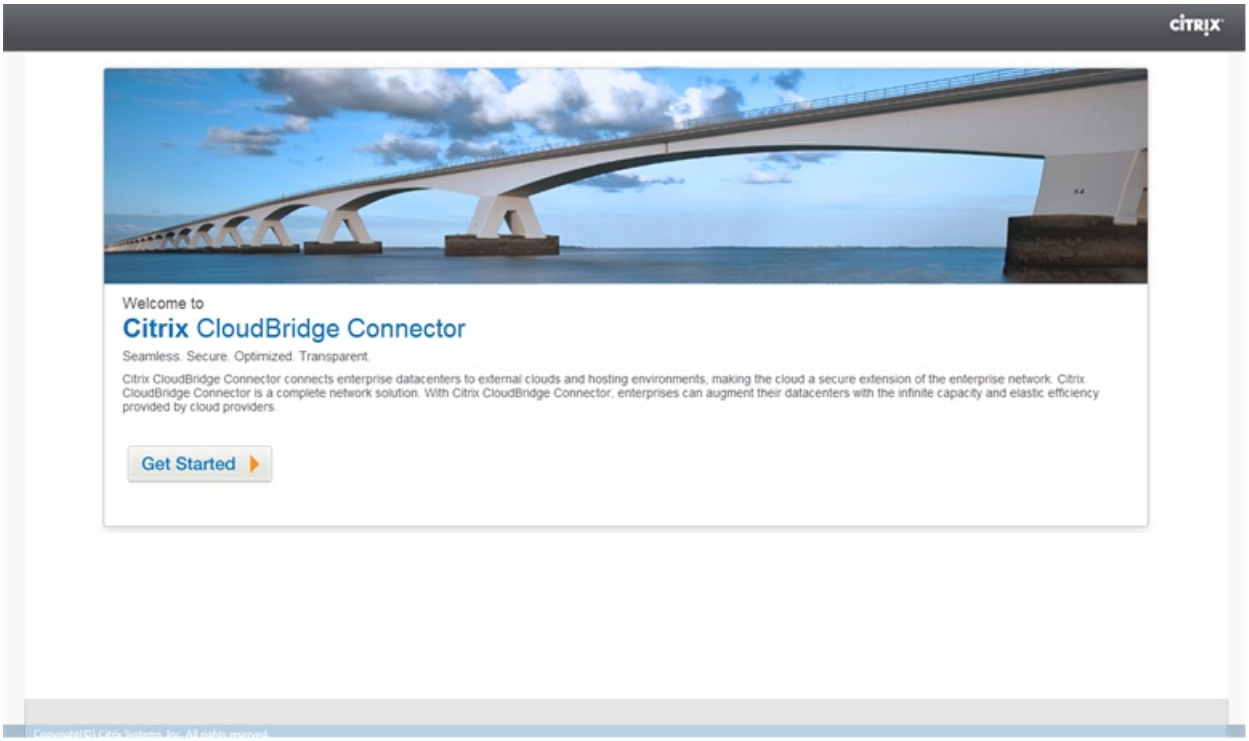
Done

> apply ns pbrs

Done
```

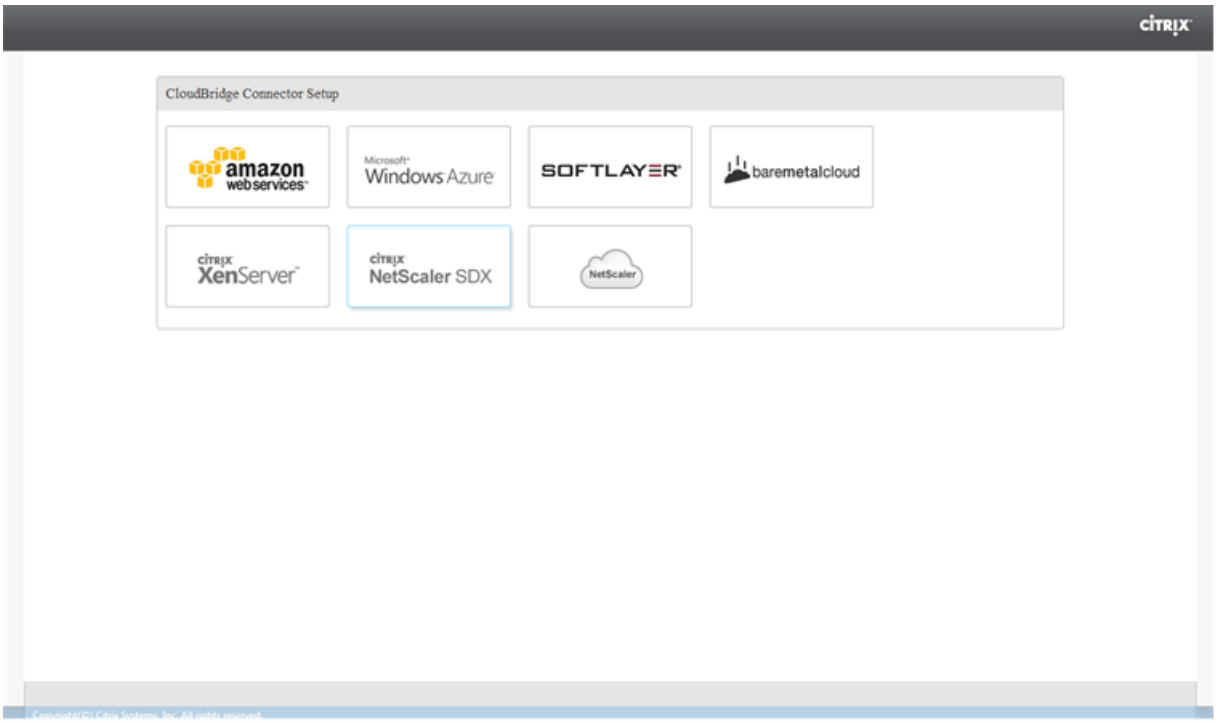
To configure a CloudBridge Connector tunnel in a NetScaler appliance by using the configuration utility

1. Type the NSIP address of a NetScaler appliance in the address line of a web browser.
2. Log on to the configuration utility of the NetScaler appliance by using your account credentials for the appliance.
3. Navigate to **System** > **CloudBridge Connector**.
4. In the right pane, under **Getting Started**, click **Create/Monitor CloudBridge**.
5. The first time you configure a CloudBridge Connector tunnel on the appliance, a **Welcome** screen appears.
6. On the **Welcome** screen click **Get Started**.



Note: If you already have a CloudBridge Connector tunnel configured on the NetScaler appliance, the Welcome screen does not appear, so you do not click Get Started.

7. In the **CloudBridge Connector Setup** pane, click **amazon web services**.



8. In the **Amazon** pane, provide your AWS account credentials: AWS Access Key ID and AWS Secret Access Key. You can obtain these access keys from the AWS GUI console. Click **Continue**.
   Note: Earlier, the Setup wizard always connects to the same AWS region even when another region is selected. As a result, configuring CloudBridge Connector tunnel to a NetScaler VPX running on the selected AWS region used to fail. This issue has been fixed now.
9. In the **NetScaler** pane, select the NSIP address of the NetScaler virtual appliance running on AWS. Then, provide your account credentials for the NetScaler virtual appliance. Click **Continue**.
10. In the **CloudBridge Connector Setting** pane, set the following parameter:
    - **CloudBridge Connector Name**—Name for the CloudBridge Connector configuration on the local appliance. Must begin with an ASCII alphabetic or underscore (_) character, and must contain only ASCII alphanumeric, underscore, hash (#), period (.), space, colon (:), at (@), equals (=), and hyphen (-) characters. Cannot be changed after the CloudBridge Connector configuration is created.
11. Under **Local Setting**, set the following parameter:
    - **Subnet IP**—IP address of the local endpoint of the CloudBridge Connector tunnel. Must be a public IP address of type SNIP.
12. Under **Remote Setting**, set the following parameter:
    - **Subnet IP**— IP address of the CloudBridge Connector tunnel end point on the AWS side. Must be an IP address of type SNIP on the NetScaler VPX instance on AWS.
    - **NAT**—Public IP address (EIP) in AWS that is mapped to the SNIP configured on the NetScaler VPX instance on AWS.
13. Under **PBR Setting**, set the following parameters:
    - **Operation**—Either the equals (=) or does not equal (!=) logical operator.
    - **Source IP Low***—Lowest source IP address to match against the source IP address of an outgoing IPv4 packet.
    - **Source IP High**—Highest source IP address to match against the source IP address of an outgoing IPv4 packet.
    - **Operation**—Either the equals (=) or does not equal (!=) logical operator.
    - **Destination IP Low***—Lowest destination IP address to match against the destination IP address of an outgoing IPv4 packet.
    - **Destination IP High**—Highest destination IP address to match against the destination IP address of an outgoing IPv4 packet.
14. (Optional) Under **Security Settings**, set the following IPSec protocol parameters for the CloudBridge Connector tunnel:
    - **Encryption Algorithm**—Encryption algorithm to be used by the IPSec protocol in the CloudBridge tunnel.
    - **Hash Algorithm**—Hash algorithm to be used by the IPSec protocol in the CloudBridge tunnel.
    - **Key**— Select one of the following IPSec authentication methods to be used by the two peers to mutually authenticate.
      - **Auto Generate Key**— Authentication based on a text string, called a pre-shared key (PSK), generated automatically by the local appliance. The PSKs keys of the peers are matched against each other for authentication.
      - **Specific Key**—Authentication based on a manually entered PSK. The PSKs of the peers are matched against each other for authentication.
        - **Pre Shared Security Key**—The text string entered for pre-shared key based authentication.
      - **Upload Certificates**—Authentication based on digital certificates.
        - **Public Key**—A local digital certificate to be used to authenticate the local peer to the remote peer before establishing IPSec security associations. The same certificate should be present and set for the Peer Public Key parameter in the peer.

- **Private Key**—Private key of the local digital certificate.
- **Peer Public Key**—Digital certificate of the peer. Used to authenticate the peer to the local end point before establishing IPSec security associations. The same certificate should be present and set for the Public key parameter in the peer.

15. Click **Done**.

The new CloudBridge Connector tunnel configuration on the NetScaler appliance in the datacenter appears on the Home tab of the configuration utility. The corresponding new CloudBridge Connector tunnel configuration on the NetScaler VPX appliance in the AWS cloud appears on the configuration utility. The current status of the CloudBridge connector tunnel is indicated in the Configured CloudBridge pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

Monitoring the CloudBridge Connector Tunnel

You can monitor the performance of CloudBridge Connector tunnels on a NetScaler appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a NetScaler appliance, see Monitoring CloudBridge Connector Tunnels.

Configuring a CloudBridge Connector Tunnel Between a NetScaler Appliance and Virtual Private Gateway on AWS

Feb 13, 2017

To connect a datacenter to Amazon Web Services (AWS), you can configure a CloudBridge Connector tunnel between a NetScaler appliance in the datacenter and a virtual private gateway on AWS. The NetScaler appliance and the virtual private gateway form the endpoints of the CloudBridge Connector tunnel and are called peers.

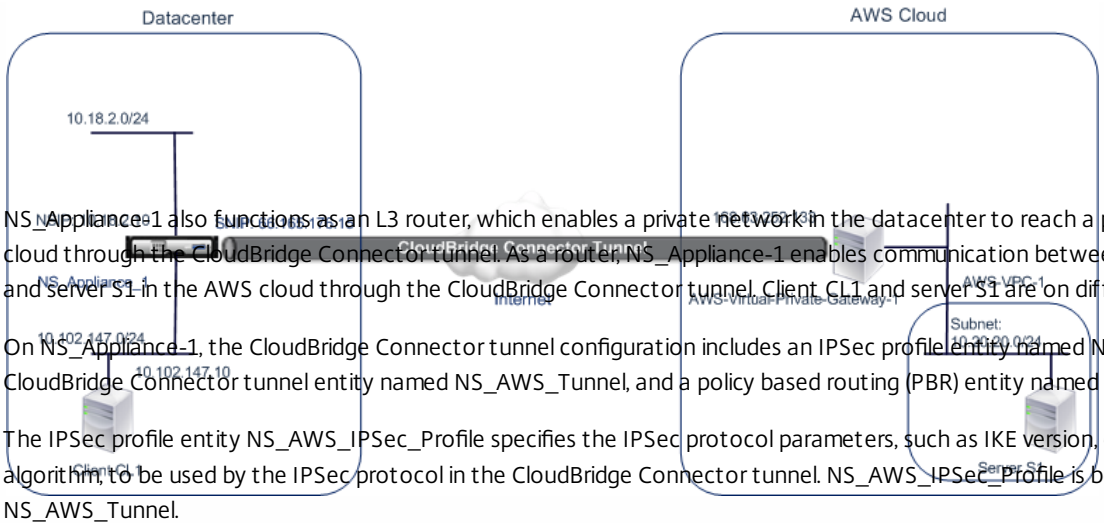
Note: You can also set up a CloudBridge Connector tunnel between a NetScaler appliance in a datacenter and a NetScaler VPX instance (instead of a virtual private gateway) on AWS. For more information, see Configuring CloudBridge Connector between Datacenter and AWS Cloud.

Virtual private gateways on AWS support the following IPSec settings for a CloudBridge Connector tunnel. Therefore, you must specify the same IPSec settings when you configure the NetScaler appliance for the CloudBridge Connector tunnel.

IPSec Properties	Setting
IPSec mode	Tunnel mode
IKE version	Version 1
IKE Authentication method	Pre-Shared Key
Encryption algorithm	AES
Hash algorithm	HMAC SHA1

Example of CloudBridge Connector Tunnel Configuration and Data Flow

As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between NetScaler appliance NS_Appliance-1 in a datacenter and virtual private gateway gateway AWS-Virtual-Private-Gateway-1 on AWS cloud.



NS_Appliance-1 also functions as an L3 router, which enables a private network in the datacenter to reach a private network in the AWS cloud through the CloudBridge Connector tunnel. As a router, NS_Appliance-1 enables communication between client CL1 in the datacenter and server S1 in the AWS cloud through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes an IPSec profile entity named NS_AWS_IPSec_Profile, a CloudBridge Connector tunnel entity named NS_AWS_Tunnel, and a policy based routing (PBR) entity named NS_AWS_Pbr.

The IPSec profile entity NS_AWS_IPSec_Profile specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, and hash algorithm, to be used by the IPSec protocol in the CloudBridge Connector tunnel. NS_AWS_IPSec_Profile is bound to IP tunnel entity NS_AWS_Tunnel.

CloudBridge Connector tunnel entity NS_AWS_Tunnel specifies the local IP address (a public IP—SNIP—address configured on the NetScaler appliance), the remote IP address (the IP address of the AWS-Virtual-Private-Gateway-1), and the protocol (IPSec) used to set up the CloudBridge Connector tunnel. NS_AWS_Tunnel is bound to policy based routing (PBR) entity NS_AWS_Pbr.

The PBR entity NS_AWS_Pbr specifies a set of conditions and a CloudBridge Connector tunnel entity (NS_AWS_Tunnel). The source IP address range and the destination IP address range are the conditions for NS_AWS_Pbr. The source IP address range and the destination IP address range are specified as a subnet in the datacenter and a subnet in the AWS cloud, respectively. Any request packet originating from a client in the subnet in the datacenter and destined to a server in the subnet on the AWS cloud matches the conditions in NS_AWS_Pbr. This packet is then considered for CloudBridge Connector processing and is sent across the CloudBridge Connector tunnel (NS_AWS_Tunnel) bound to the PBR entity.

The following table lists the settings used in this example.

Entity	Name	Details
Settings highlight of the CloudBridge Connector tunnel setup		
IP address of the CloudBridge Connector tunnel end point (NS_Appliance-1) in the datacenter side		66.165.176.15
IP address of the CloudBridge Connector tunnel end point (AWS-Virtual-Private-Gateway-1) in the AWS		168.63.252.133
Datacenter Subnet, the traffic of which is to traverse the CloudBridge Connector tunnel		10.102.147.0/24
AWS Subnet, the traffic of which is to traverse the CloudBridge Connector tunnel		10.20.20.0/24
Settings on NetScaler appliance NS_Appliance-1 in Datacenter		
	SNIP1(for reference purposes only)	66.165.176.15
IPSec profile	NS_AWS_IPSec_Profile	• IKE version = v1

		• Encryption algorithm = AES • Hash algorithm = HMAC SHA1
CloudBridge Connector tunnel	NS_AWS_Tunnel	• Remote IP = 168.63.252.133 • Local IP= 66.165.176.15 • Tunnel protocol = IPSec • IPSec profile= NS_AWS_IPSec_Profile
Policy based route	NS_AWS_Pbr	• Source IP range = Subnet in the datacenter =10.102.147.0-10.102.147.255 • Destination IP range =Subnet in AWS =10.20.20.0-10.20.20.255 • IP Tunnel = NS_AWS_Tunnel
Settings on Amazon AWS		
Customer Gateway	AWS-Customer-Gateway-1	• Routing = Static • IP Address = Internet-routable CloudBridge Connector tunnel endpoint IP address on the NetScaler side = 66.165.176.15
Virtual Private Gateway	AWS-Virtual-Private-Gateway-1	• Associated VPC = AWS-VPC-1

VPN Connection	AWS-VPN-Connection-1	• Customer Gateway = AWS-Customer-Gateway-1
		• Virtual Private Gateway= Virtual-Private-Gateway-1
		• Routing Options
		  • Type = Static
		  • Static IP Prefixes = Subnets on the NetScaler side = 10.102.147.0/24

Points to Consider for a CloudBridge Connector Tunnel Configuration

Before configuring a CloudBridge Connector tunnel between a NetScaler appliance and AWS gateway, consider the following points:

1. AWS supports the following IPSec settings for a CloudBridge Connector tunnel. Therefore, you must specify the same IPSec settings when you configure the NetScaler appliance for the CloudBridge Connector tunnel.

- IKE version = v1
- Encryption algorithm = AES
- Hash algorithm = HMAC SHA1

2. You must configure the firewall at the NetScaler end to allow the following.

- Any UDP packets for port 500
- Any UDP packets for port 4500
- Any ESP (IP protocol number 50) packets

3. You must configure Amazon AWS before specifying the tunnel configuration on the NetScaler, because the public IP address of the AWS

end (gateway) of the tunnel and the PSK are automatically generated when you set up the tunnel configuration in AWS. You need this information for specifying the tunnel configuration on the NetScaler appliance.

4. AWS gateway supports static routes and the BGP protocol for route updates. The NetScaler appliance does not support the BGP protocol in a CloudBridge Connector tunnel to AWS gateway. Therefore, appropriate static routes must be used on both sides of the CloudBridge Connector tunnel for proper routing of traffic through the tunnel.

Configuring Amazon AWS for the CloudBridge Connector Tunnel

To create a CloudBridge Connector tunnel configuration on Amazon AWS, use the Amazon AWS Management Console, which is a web based graphical interface for creating and managing resources on Amazon AWS.

Before you begin the CloudBridge Connector tunnel configuration on AWS cloud, make sure that:

- You have a user account for Amazon AWS cloud.
- You have a virtual private cloud whose networks you want to connect to the networks at the NetScaler side through the CloudBridge Connector tunnel.
- You are familiar with the Amazon AWS Management Console.

Note: The procedures for configuring Amazon AWS for a CloudBridge Connector tunnel might change over time, depending on the Amazon AWS release cycle. Citrix recommends the following Amazon AWS documentation for the latest procedures.

- http://docs.aws.amazon.com/AmazonVPC/latest/UserGuide/VPC_VPN.html

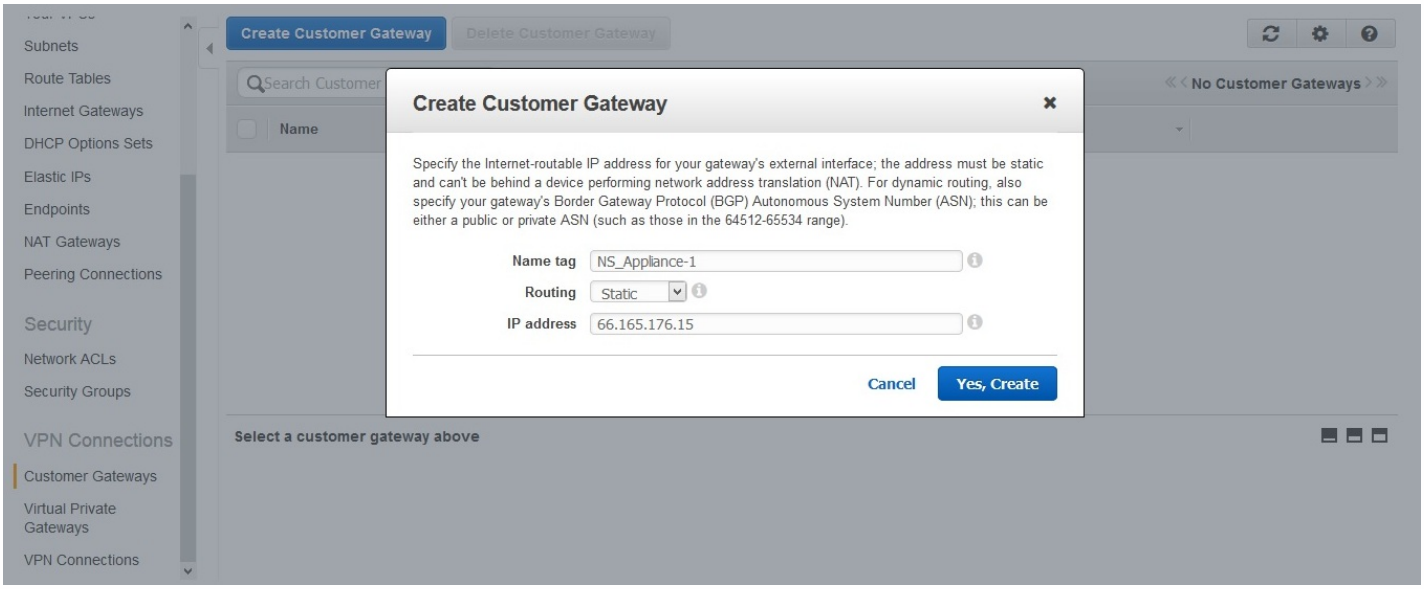
To configure a CloudBridge connector tunnel between a NetScaler and AWS gateway perform the following tasks on the AWS Management Console:

- **Create a Customer Gateway**. A customer gateway is an AWS entity that represents a CloudBridge Connector tunnel endpoint. For a CloudBridge Connector tunnel between a NetScaler appliance and AWS gateway, the customer gateway represents the NetScaler appliance on AWS. The customer gateway specifies a name, the type of routing (static or BGP) used in the tunnel, and the CloudBridge Connector tunnel endpoint IP address on the NetScaler side. The IP address can be an Internet-routable NetScaler owned subnet IP (SNIP) address or, if the NetScaler appliance is behind a NAT device, an Internet-routable NAT IP address that represents the SNIP address.
- **Create a Virtual Private Gateway and attach it to a VPC**. A virtual private gateway is a CloudBridge Connector tunnel endpoint at the AWS side. When you create a virtual private gateway, you assigned it a name or allow AWS to assign the name. You then associate the virtual private gateway with a VPC. This association enables the subnets of the VPC to connect to the subnets at the NetScaler side through the CloudBridge Connector tunnel.
- **Create a VPN Connection**. A VPN connection specifies a customer gateway and a virtual private gateway between which a CloudBridge Connector tunnel is to be created. It also specifies an IP prefix for the networks at the NetScaler side. Only IP prefixes that are known to the virtual private gateway (through static route entry) can receive traffic from the VPC through the tunnel. Also, the virtual private gateway does not route any traffic not destined to the specified IP prefixes through the tunnel. After configuring a VPN connection, you might have to wait few minutes for it to be created.
- **Configure Routing Options**. For the VPC's network to reach the networks at the NetScaler side through the CloudBridge Connector tunnel, you must configure the VPC's routing table to include routes for the networks at the NetScaler side and point those routes to the virtual private gateway. You can include routes in a VPC's routing table in one of the following ways:
  - **Enable Route Propagation**. You can enable route propagation for your routing table, so that routes are automatically propagated to the table. The static IP prefixes that you specify for VPN configuration are propagated to the routing table after you've created the VPN connection.
  - **Enter Static Routes Manually**. If you do not enable route propagation, you must manually enter the static routes for the networks at the NetScaler side.
- **Download Configuration**. After the CloudBridge Connector tunnel (VPN connection) configuration is created on AWS, download the configuration file of the VPN connection to your local system. You might need the information in the configuration file for configuring

the CloudBridge Connector tunnel on the NetScaler appliance.

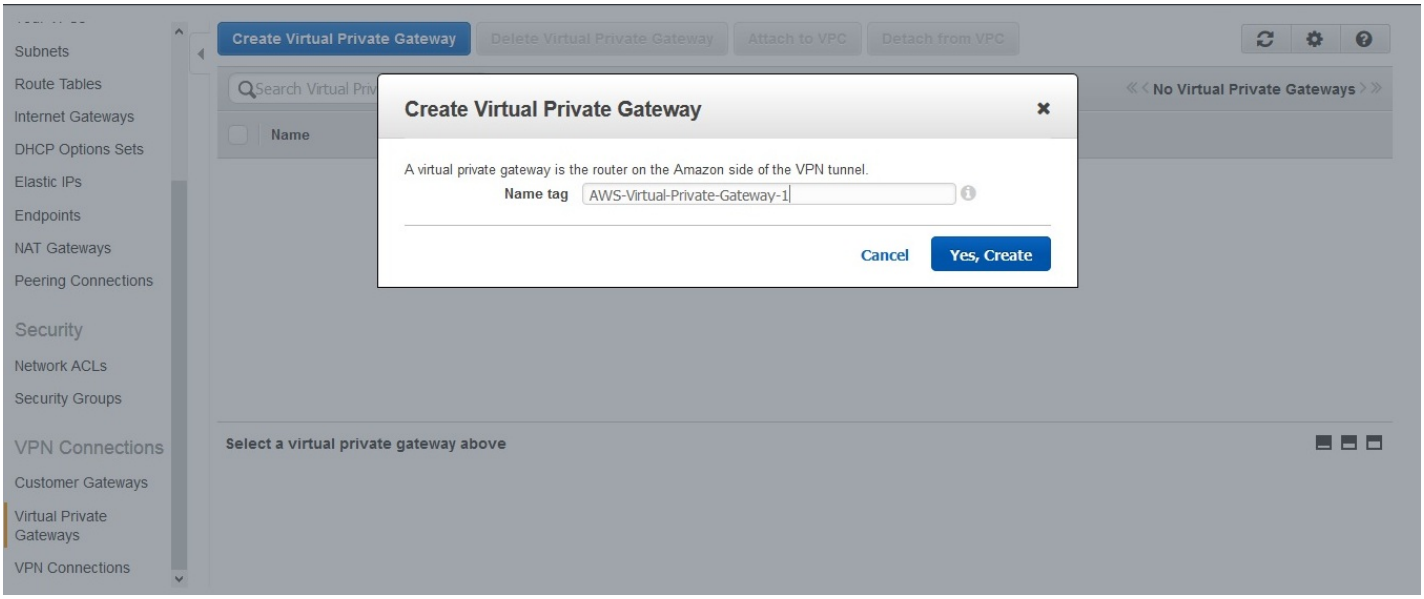
To create a customer gateway

1. Open the Amazon VPC console at https://console.aws.amazon.com/vpc/.
2. Navigate to **VPN Connections** > **Customer Gateways** and click on **Create Customer Gateway**.
3. In the **Create Customer Gateway** dialog box, set the following parameters and then click **Yes, Create**:
   - **Name tag**. A name for the customer gateway.
   - **Routing list**. Type of routing between NetScaler appliance and AWS virtual private gateway for advertising routes to each other through the CloudBridge Connector tunnel. Select **Static Routing** from the **Routing** list. **Note**: The NetScaler appliance does not support the BGP protocol in a CloudBridge Connector tunnel to AWS gateway. Therefore, appropriate static routes must be used on both sides of the CloudBridge Connector tunnel for proper routing of traffic through the tunnel.
   - **IP Address**. Internet-routable CloudBridge Connector tunnel endpoint IP address on the NetScaler side. The IP address can be an Internet-routable NetScaler owned subnet IP (SNIP) address or, if the NetScaler appliance is behind a NAT device, an Internet-routable NAT IP address that represents the SNIP address.



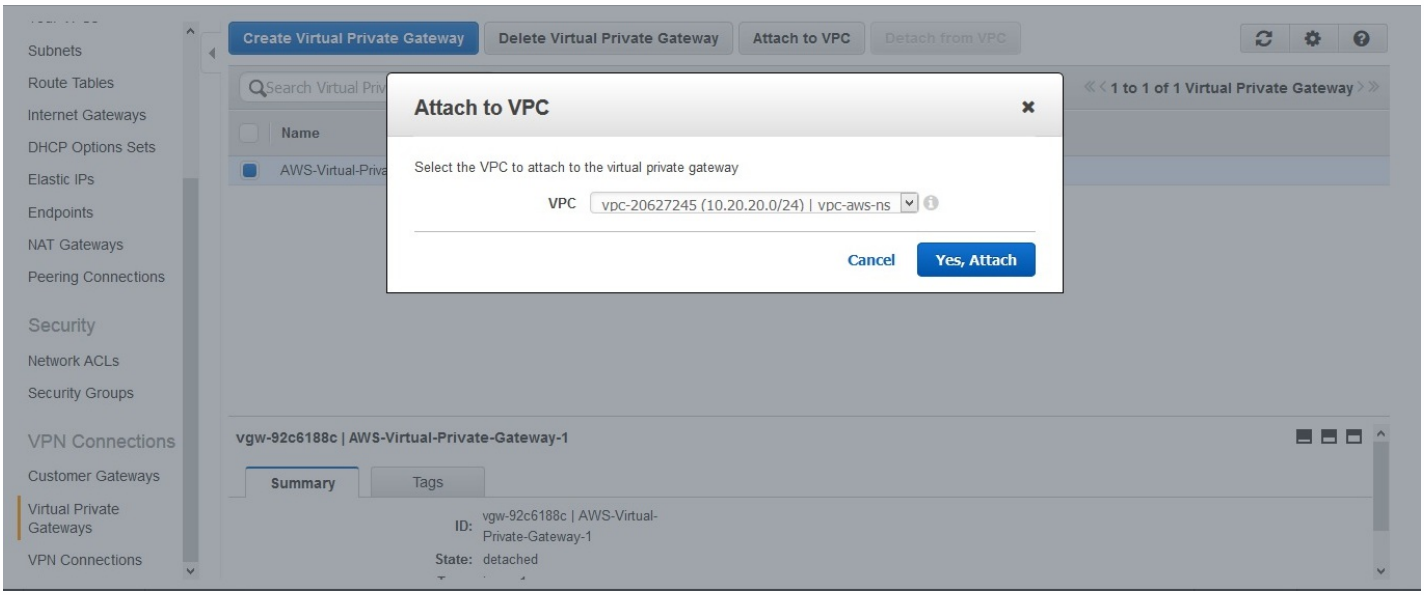
To create a virtual private gateway and attach it to a VPC

1. Navigate to **VPN Connections** > **Virtual Private Gateways**, and then click Create Virtual Private Gateway.
2. Enter a name for the virtual private gateway, and then click Yes, Create.



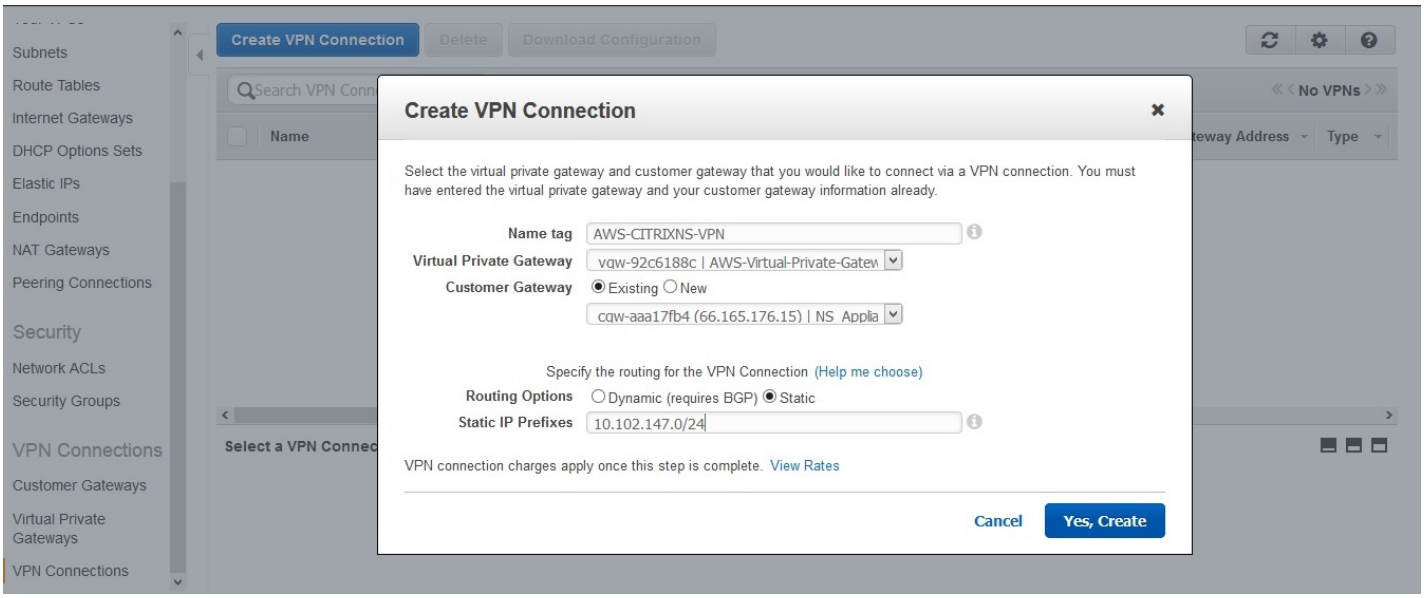
3. Select the virtual private gateway that you created, and then click Attach to VPC.

4. In the Attach to VPC dialog box, select your VPC from the list, and then choose Yes, Attach.



To create a VPN connection

1. Navigate to VPN Connections > VPN Connections and then click Create VPN Connection.
2. In the Create VPN Connection dialog box set the following parameters and then choose Yes, Create:
   - **Name tag**. A name for the VPN connection.
   - **Virtual Private Gateway**. Select the virtual private gateway that you created earlier.
   - **Customer Gateway**. Select Existing. Then, from the drop down list, select the customer gateway that you created earlier.
   - **Routing Options**. Type of routing between the virtual private gateway and customer gateway (NetScaler appliance). Select Static. In the Static IP Prefixes field, specify the IP prefixes for the subnet on the NetScaler side, separated by commas.



To enable route propagation

1. Navigate to **Route Tables** and select the routing table that's associated with the subnet whose traffic is to traverse the CloudBridge Connector tunnel.
   Note: By default, this is the main routing table for the VPC.
2. On the **Route Propagation** tab in the details pane, choose **Edit**, select the virtual private gateway, and then choose **Save**.

To manually enter static routes

1. Navigate to **Route Tables** and select your routing table.
2. On the **Routes** tab, click **Edit**.
3. In the **Destination** field, enter the static route used by your CloudBridge Connector tunnel (VPN connection).
4. Select the virtual private gateway ID from the **Target** list, and then click **Save**.

To download the configuration file

1. Navigate to **VPN Connection**, select a VPN connection, and then click **Download Configuration**.
2. In the **Download Configuration** dialog box, set the following parameters, and then click **Yes, Download**.
   - **Vendor**. Select **Generic**.
   - **Platform**. Select **Generic**.
   - **Software**. Select **Vendor Agnostic**.

Configuring the NetScaler Appliance for the CloudBridge Connector Tunnel

To configure a CloudBridge Connector tunnel between a NetScaler appliance and a virtual private gateway on AWS cloud, perform the following tasks on the NetScaler appliance. You can use either the NetScaler command line or the configuration utility:

- **Create an IPSec profile**. An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm and PSK to be used by the IPSec protocol in the CloudBridge Connector tunnel.
- **Create an IP tunnel that uses IPSec protocol and associate the IPSec profile with it**. An IP tunnel specifies the local IP address (a SNIP address configured on the NetScaler appliance), remote IP address (the public IP address of the virtual private gateway in AWS), protocol (IPSec) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.
- **Create a PBR rule and associate it with the IP tunnel**. A PBR entity specifies a set of rules and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP address range are the conditions for the PBR entity. Set the source IP address range to specify the NetScaler-side subnet whose traffic is to traverse the tunnel, and set the destination IP address range to specify the AWS VPC subnet whose traffic is to traverse the CloudBridge Connector tunnel. Any request packet that originates from a client in the subnet on the NetScaler side and is destined to a server in the AWS cloud subnet, and matches the source and destination IP range of the PBR entity, is sent across the CloudBridge Connector tunnel associated with the PBR entity.

To create an IPSEC profile by using the NetScaler command line

At the Command prompt, type:

- **add ipsec profile** <name> -**psk** <string> -**ikeVersion** v1
- **show ipsec profile** <name>

To create an IPSEC tunnel and bind the IPSEC profile to it by using the NetScaler command line

At the Command prompt, type:

- **add ipTunnel** <name> <remote> <remoteSubnetMask> <local> -**protocol** IPSEC –**ipsecProfileName** <string>
- **show ipTunnel** <name>

To create a PBR rule and bind the IPSEC tunnel to it by using the NetScaler command line

At the Command prompt, type:

- **add pbr** <pbrName> ALLOW –**srcIP** <subnet-range> -**destIP** <subnet-range> -**ipTunnel** <tunnelName>
- **apply pbrs**
- **show pbr** <pbrName>

Sample configuration COPY

```
The following commands create all settings of NetScaler appliance NS_Appliance-1 used in "Example of CloudBridge Connector Configuration and Data Flow

> add ipsec profile NS_AWS_IPSec_Profile -psk  DkiMgMdcbqvYREEuIvxsbKkW0Foyabcd -ikeVersion v1 –lifetime 31536000

Done

> add iptunnel NS_AWS_Tunnel 168.63.252.133 255.255.255.255 66.165.176.15 –protocol IPSEC –ipsecProfileName NS_AWS_IPSec_Profile

Done

> add pbr NS_AWS_Pbr -srcIP 10.102.147.0-10.102.147.255 –destIP 10.20.0.0-10.20.255.255 –ipTunnel NS_AWS_Tunnel

Done

> apply pbrs

Done
```

To create an IPSEC profile by using the configuration utility

1. Navigate to **System** > **CloudBridge Connector** > **IPSec Profile**.
2. In the details pane, click **Add**.
3. In the **Add IPSec Profile** dialog box, set the following parameters:

- Name
- Encryption Algorithm
- Hash Algorithm
- IKE Protocol Version (select V1)

4. Select the **Pre-shared Key Authentication** method and set the **Pre-Shared Key Exists** parameter.
5. Click **Create**, and then click **Close**.

To create an IP tunnel and bind the IPSEC profile to it by using the configuration utility

1. Navigate to **System** > **CloudBridge Connector** > **IP Tunnels**.
2. On the **IPv4 Tunnels** tab, click Add.
3. In the **Add IP Tunnel** dialog box, set the following parameters:

- Name
- Remote IP
- Remote Mask
- Local IP Type (In the Local IP Type drop down list, select Subnet IP).
- Local IP (All the configured IPs of the selected IP type are in the Local IP drop down list. Select the desired IP from the list.)
- Protocol

- IPSec Profile

4. Click **Create**, and then click **Close**.

To create a PBR rule and bind the IPSEC tunnel to it by using the configuration utility

1. Navigate to **System** > **Network** > **PBR**.

2. On the **PBR** tab, click **Add**.

3. In the **Create PBR** dialog box, set the following parameters:

- Name
- Action
- Next Hop Type (Select IP Tunnel)
- IP Tunnel Name
- Source IP Low
- Source IP High
- Destination IP Low
- Destination IP High

4. Click **Create**, and then click **Close**.

The corresponding new CloudBridge Connector tunnel configuration on the NetScaler appliance appears in the configuration utility.

The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Connector pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

Monitoring the CloudBridge Connector Tunnel

You can monitor the performance of CloudBridge Connector tunnels on a NetScaler appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a NetScaler appliance, see Monitoring CloudBridge Connector Tunnels.

Configuring a CloudBridge Connector Tunnel Between a Datacenter and Azure Cloud

Feb 13, 2017

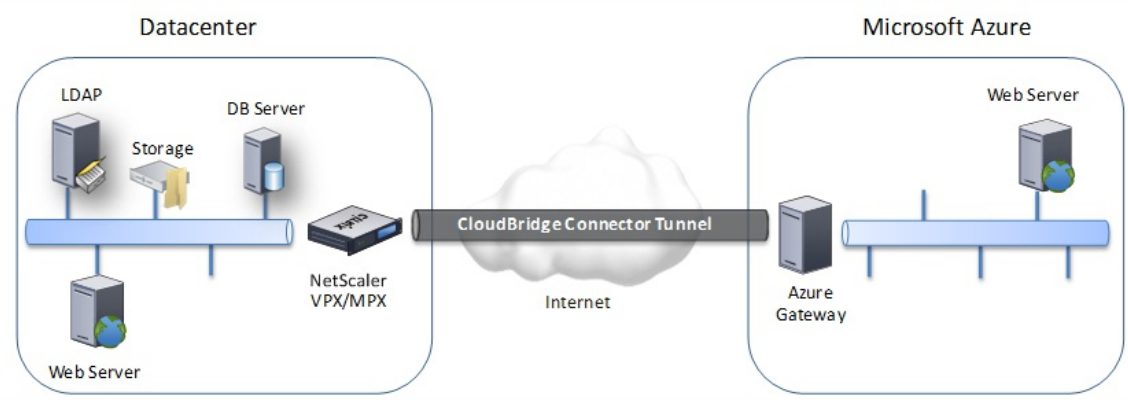
The NetScaler appliance provides connectivity between your enterprise datacenters and the Microsoft cloud hosting provider, Azure, making Azure a seamless extension of the enterprise network. NetScaler encrypts the connection between the enterprise datacenter and Azure cloud so that all data transferred between the two is secure.

This section includes the following:

- How CloudBridge Connector Tunnel Works
- Example of CloudBridge Connector Tunnel Configuration and Data Flow
- Points to Consider for a CloudBridge Connector tunnel Configuration
- Configuring the CloudBridge Connector Tunnel
- Monitoring the CloudBridge Connector Tunnel

How CloudBridge Connector Tunnel Works

To connect a datacenter to Azure cloud, you set up a CloudBridge Connector tunnel between a NetScaler appliance that resides in the datacenter and a gateway that resides in the Azure cloud. The NetScaler appliance in the datacenter and the gateway in Azure cloud are the end points of the CloudBridge Connector tunnel and are called peers of the CloudBridge Connector tunnel.



A CloudBridge Connector tunnel between a datacenter and Azure cloud uses the open-standard Internet Protocol security (IPSec) protocol suite, in tunnel mode, to secure communications between peers in the CloudBridge Connector tunnel. In a CloudBridge Connector tunnel, IPSec ensures:

- Data integrity
- Data origin authentication
- Data confidentiality (encryption)
- Protection against replay attacks

IPSec uses the tunnel mode in which the complete IP packet is encrypted and then encapsulated. The encryption uses the Encapsulating Security Payload (ESP) protocol, which ensures the integrity of the packet by using a HMAC hash function and ensures confidentiality by using an encryption algorithm. The ESP protocol, after encrypting the payload and calculating the HMAC, generates an ESP header and inserts it before the encrypted IP packet. The ESP protocol also generates an ESP trailer and inserts it at the end of the packet.

The IPSec protocol then encapsulates the resulting packet by adding an IP header before the ESP header. In the IP header, the destination IP address is set to the IP address of the CloudBridge Connecter peer.

Peers in the CloudBridge Connector tunnel use the Internet Key Exchange version 1 (IKEv1) protocol (part of the IPSec protocol suite) to negotiate secure communication, as follows:

1. The two peers mutually authenticate with each other, using pre-shared key authentication, in which the peers exchange a text string called a pre-shared key (PSK). The pre-shared keys are matched against each other for authentication. Therefore, for the authentication to be successful, you must configure the same pre-shared key on each of the peers.
2. The peers then negotiate to reach agreement on:

- An encryption algorithm
- Cryptographic keys for encrypting data on one peer and decrypting it on the other.

This agreement upon the security protocol, encryption algorithm and cryptographic keys is called a Security Association (SA). SAs are one-way (simplex). For example, when a CloudBridge Connector tunnel is set up between a NetScaler appliance in a datacenter and a gateway in an Azure cloud, both the datacenter appliance and the Azure gateway have two SAs. One SA is used for processing out-bound packets, and the other SA is used for processing inbound packets. SAs expire after a specified interval of time, which is called the lifetime.

Example of CloudBridge Connector Tunnel Configuration and Data Flow

As an illustration of CloudBridge Connector Tunnel, consider an example in which a CloudBridge Connector tunnel is set up between NetScaler appliance CB_Appliance-1 in a datacenter and gateway Azure_Gateway-1 in Azure cloud.

CB_Appliance-1 also functions as an L3 router, which enables a private network in the datacenter to reach a private network in the Azure cloud through the CloudBridge Connector tunnel. As a router, CB_Appliance-1 enables communication between client CL1 in the datacenter and server S1 in the Azure cloud through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On CB_Appliance-1, the CloudBridge Connector tunnel configuration includes an IPSec profile entity named CB_Azure_IPSec_Profile, a CloudBridge Connector tunnel entity named CB_Azure_Tunnel, and a policy based routing (PBR) entity named CB_Azure_Pbr.

The IPSec profile entity CB_Azure_IPSec_Profile specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, and hash algorithm, to be used by the IPSec protocol in the CloudBridge Connector tunnel. CB_Azure_IPSec_Profile is bound to IP tunnel entity CB_Azure_Tunnel.

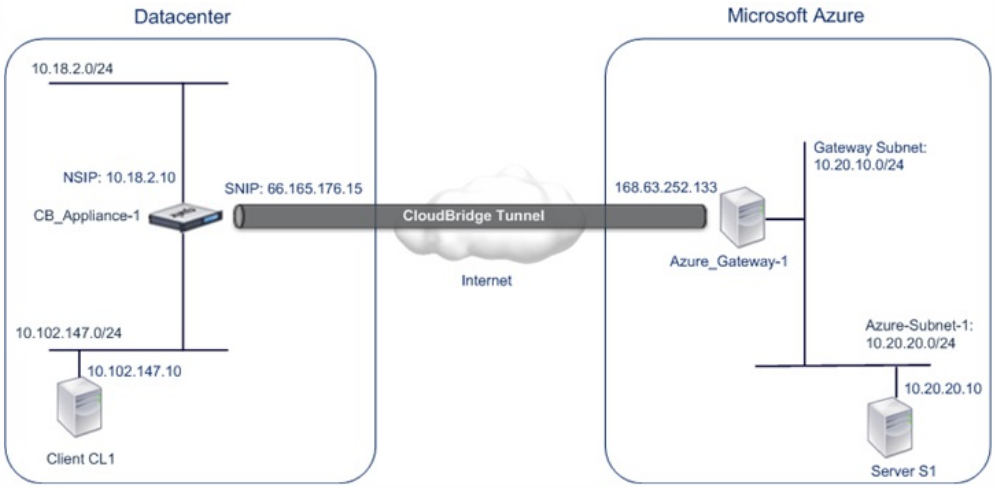
CloudBridge Connector tunnel entity CB_Azure_Tunnel specifies the local IP address (a public IP (SNIP) address configured on the NetScaler appliance), the remote IP address (the IP address of the Azure_Gateway-1), and the protocol (IPSec) used to set up the CloudBridge Connector tunnel. CB_Azure_Tunnel is bound to the PBR entity CB_Azure_Pbr.

The PBR entity CB_Azure_Pbr specifies a set of conditions and a CloudBridge Connector tunnel entity (CB_Azure_Tunnel). The source IP address range and the destination IP address range are the conditions for CB_Azure_Pbr. The source IP address range and the destination IP address range are specified as a subnet in the datacenter and a subnet in the Azure cloud, respectively. Any request packet originating from a client in the subnet in the datacenter and destined to a server in the subnet on the Azure cloud matches the conditions in CB_Azure_Pbr. This packet is then considered for CloudBridge processing and is sent across the CloudBridge Connector tunnel (CB_Azure_Tunnel) bound to the PBR entity.

On Microsoft Azure, the CloudBridge Connector tunnel configuration includes a local network entity named My-Datacenter-Network, a virtual network entity named Azure-Network-for-CloudBridge-Tunnel, and a gateway named Azure_Gateway-1.

The local (local to Azure) network entity My-Datacenter-Network specifies the IP address of the NetScaler appliance on the datacenter side, and the datacenter subnet whose traffic is to traverse the CloudBridge Connector tunnel. The virtual network entity Azure-Network-for-CloudBridge-Tunnel defines a private subnet named Azure-Subnet-1 in Azure. The traffic of the subnet traverses the CloudBridge Connector tunnel. The server S1 is provisioned in this subnet.

The local network entity My-Datacenter-Network is associated with the virtual network entity Azure-Network-for-CloudBridge-Tunnel. This association defines the remote and local network details of the CloudBridge Connector tunnel configuration in Azure. Gateway Azure_Gateway-1 was created for this association to become the CloudBridge end point at the Azure end of the CloudBridge Connector tunnel.



The following table lists the settings used in this example.

Entity	Name	Details
Settings highlight of the CloudBridge Connector tunnel setup		
IP address of the CloudBridge Connector tunnel end point (CB_Appliance-1) in the datacenter side	66.165.176.15	
IP address of the CloudBridge Connector tunnel end point (Azure_Gateway-1) in the Azure	168.63.252.133	
Datacenter Subnet, the traffic of which is to traverse the CloudBridge Connector tunnel	10.102.147.0/24	
Azure Subnet, the traffic of which is to traverse the CloudBridge Connector tunnel	10.20.0.0/16	
Settings on NetScaler appliance CB_Appliance-1 in Datacenter		
	SNIP1(for reference purposes only)	66.165.176.15
IPSec profile	CB_Azure_IPSec_Profile	• IKE version = v1 • Encryption algorithm = AES • Hash algorithm = HMAC SHA1
CloudBridge Connector tunnel	CB_Azure_Tunnel	• Remote IP = 168.63.252.133 • Local IP= 66.165.176.15 • Tunnel protocol = IPSec • IPSec profile= CB_Azure_IPSec_Profile
Policy based route	CB_Azure_Pbr	• Source IP range = Subnet in the datacenter =10.102.147.0-10.102.147.255 • Destination IP range =Subnet in Azure =10.20.0.0-10.20.255.255 • IP Tunnel = CB_Azure_Tunnel

Entity Settings on Microsoft Azure	Name	Details
Public IP Address of the Azure_Gateway-1		168.63.252.133
Local Network	My-Datacenter-Network	• VPN Device IP address =SNIP address of the NetScaler appliance = 66.165.176.15 • Address space= Subnet in datacenter =10.102.147.0/24
Virtual Network	Azure-Network-for-CloudBridge-Tunnel	• Address Space= 10.20.0.0/16 • Subnet in Azure=Azure-Subnet-1= 10.20.20.0/24 • Local Network=My-Datacenter-Network • Gateway Subnet=10.20.10.0/24

Points to Consider for a CloudBridge Connector tunnel Configuration

Updated: 2014-04-15

Before configuring a CloudBridge Connector tunnel between a NetScaler appliance in datacenter and Microsoft Azure, consider the following points:

1. The NetScaler appliance must have a public facing IPv4 address (type SNIP) to use as a tunnel end-point address for the CloudBridge Connector tunnel. Also, the NetScaler appliance should not be behind a NAT device.
2. Azure supports the following IPSec settings for a CloudBridge Connector tunnel. Therefore, you must specify the same IPSec settings while configuring the NetScaler for the CloudBridge Connector tunnel.
   - IKE version = v1
   - Encryption algorithm = AES
   - Hash algorithm = HMAC SHA1
3. You must configure the firewall in the datacenter edge to allow the following.
   - Any UDP packets for port 500
   - Any UDP packets for port 4500
   - Any ESP (IP protocol number 50) packets
4. IKE re-keying, which is renegotiation of new cryptographic keys between the CloudBridge Connector tunnel end points to establish new SAs, is not supported. When the Security Associations (SAs) expire, the tunnel goes into the DOWN state. Therefore, you must set a very large value for the lifetimes of SAs.
5. You must configure Microsoft Azure before specifying the tunnel configuration on the NetScaler, because the public IP address of the Azure end (gateway) of the tunnel, and the PSK, are automatically generated when you set up the tunnel configuration in Azure. You need this information for specifying the tunnel configuration on the NetScaler.

Configuring the CloudBridge Connector Tunnel

Updated: 2014-04-15

For setting up a CloudBridge Connector tunnel between your datacenter and Azure, you must install CloudBridge VPX/MPX in your datacenter, configure Microsoft Azure for the CloudBridge Connector tunnel, and then configure the NetScaler appliance in the data center for the CloudBridge Connector tunnel.

Configuring a CloudBridge Connector tunnel between a NetScaler appliance in datacenter and Microsoft Azure consists of the following tasks:

1. **Setting up the NetScaler appliance in the datacenter**. This task involves deploying and configuring a NetScaler physical appliance (MPX), or provisioning and configuring a NetScaler virtual appliance (VPX) on a virtualization platform in the datacenter.
2. **Configuring Microsoft Azure for the CloudBridge Connector tunnel**. This task involves creating local network, virtual network, and gateway entities in Azure. The local network entity specifies the IP address of the CloudBridge Connector tunnel end point (the NetScaler appliance) on the datacenter side, and the datacenter subnet whose traffic is to traverse the CloudBridge Connector tunnel. The virtual network defines a network on Azure. Creating the virtual network includes defining a subnet whose traffic is to traverse the CloudBridge Connector tunnel to be formed. You then associate the local network with the virtual network. Finally, you create a gateway that becomes

the end point at the Azure end of the CloudBridge Connector tunnel.

3. **Configuring the NetScaler appliance in the datacenter for the CloudBridge Connector tunnel**. This task involves creating an IPSec profile, an IP tunnel entity, and a PBR entity in the NetScaler appliance in datacenter. The IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and PSK, to be used in the CloudBridge Connector tunnel. The IP tunnel specifies the IP address of both the CloudBridge Connector tunnel end points (the NetScaler appliance in datacenter and the gateway in Azure) and the protocol to be used in the CloudBridge Connector tunnel. You then associate the IPSec profile entity with the IP tunnel entity. The PBR entity specifies the two subnets, in the datacenter and in the Azure cloud, that are to communicate with each other through the CloudBridge Connector tunnel. You then associate the IP tunnel entity with the PBR entity.

Configuring Microsoft Azure for the CloudBridge Connector tunnel

Updated: 2014-04-15

To create a CloudBridge Connector tunnel configuration on Microsoft Azure, use the Microsoft Windows Azure Management Portal, which is a web based graphical interface for creating and managing resources on Microsoft Azure.

Before you begin the CloudBridge Connector tunnel configuration on Azure cloud, make sure that:

- You have a user account for Microsoft Azure.
- You have a conceptual understanding of Microsoft Azure.
- You are familiar with the Microsoft Windows Azure Management Portal.

Note: The procedures for configuring Microsoft Azure for a CloudBridge Connector tunnel might change over time, depending on the Microsoft Azure release cycle. Citrix recommends the following Microsoft Azure documentation for the latest procedures.

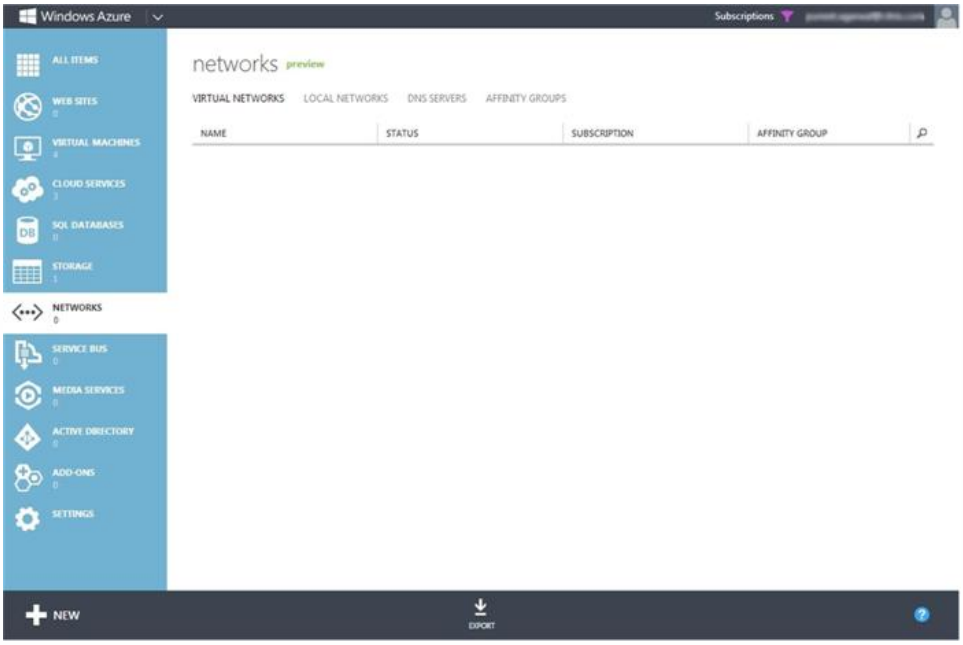
- http://www.windowsazure.com/en-us/manage/services/networking/cross-premises-connectivity/

To configure a CloudBridge Connector tunnel between a datacenter and an Azure cloud, perform the following tasks on Microsoft Azure by using the Microsoft Windows Azure Management Portal:

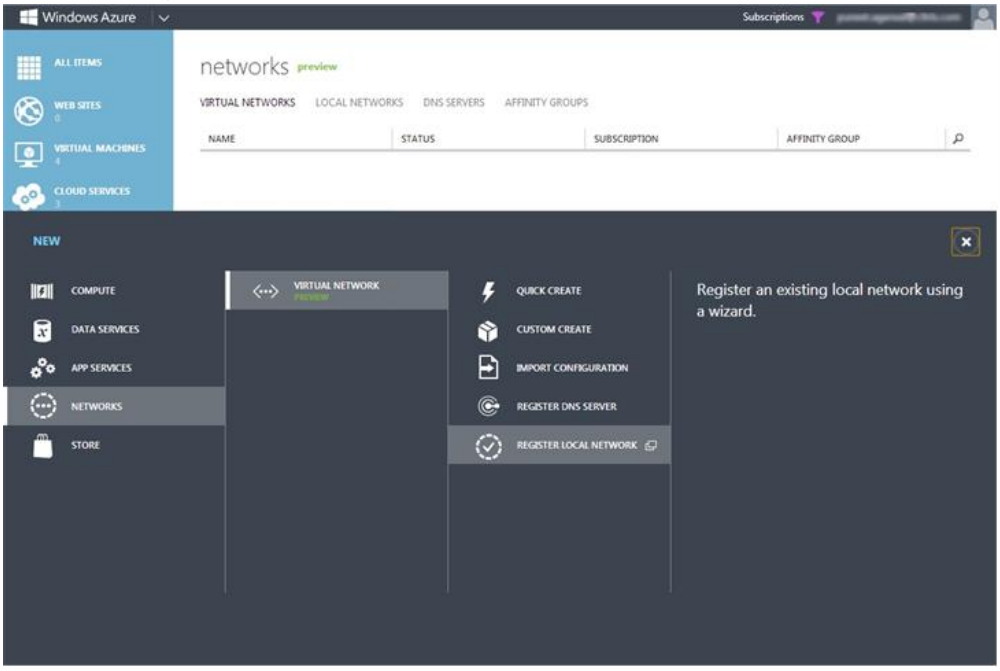
- **Create a local network entity**. Create a local network entity in Windows Azure for specifying the network details of the datacenter. A local network entity specifies the IP address of the CloudBridge Connector tunnel end point (the NetScaler) on the datacenter side and the datacenter subnet whose traffic is to traverse the CloudBridge Connector tunnel.
- **Create a Virtual Network**. Create virtual network entity that defines a network on Azure. This task includes defining a private address space, where you provide a range of private addresses and subnets belonging to the range specified in the address space. The traffic of the subnets will traverse the CloudBridge Connector tunnel. You then associate a local network entity with the virtual network entity. This association lets Azure create a configuration for a CloudBridge Connector tunnel between the virtual network and the data center network. A gateway (to be created) in Azure for this virtual network will be the CloudBridge end point at the Azure end of the CloudBridge Connector tunnel. You then define a private subnet for the gateway to be created. This subnet belongs to the range specified in the address space in the virtual network entity.
- **Create a gateway in Windows Azure**. Create a gateway that becomes the end point at the Azure end of the CloudBridge Connector tunnel. Azure, from its pool of public IP addresses, assigns an IP address to the gateway created.
- **Gather the public IP address of the gateway and the pre-shared key.** For a CloudBridge Connector tunnel configuration on Azure, the public IP address of the gateway and the pre-shared Key (PSK) are automatically generated by Azure. Make a note of this information. You will need it for configuring the CloudBridge Connector tunnel on the NetScaler in datacenter.

To specify a local network by using the Microsoft Windows Azure Management Portal

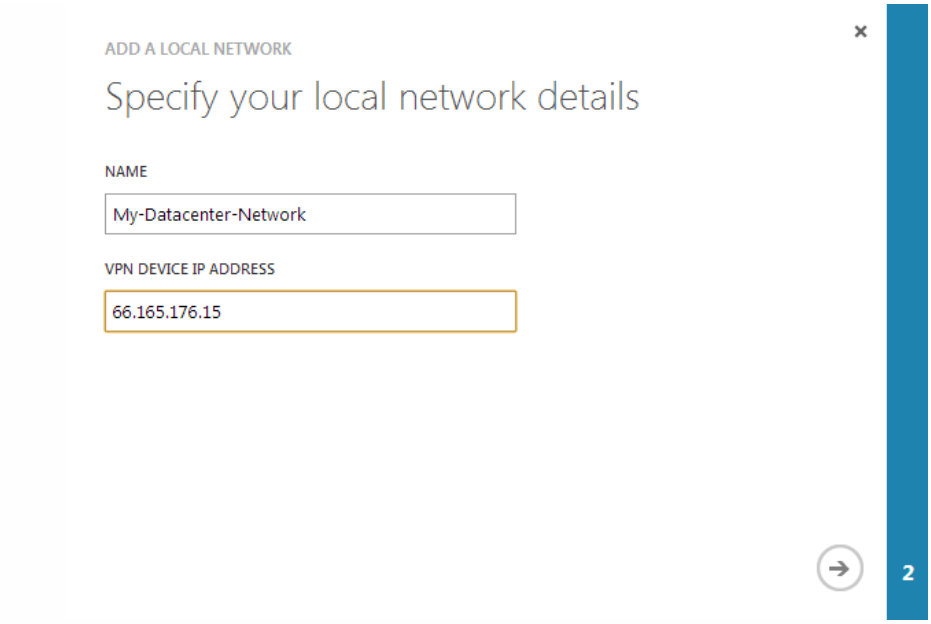
1. In the left pane, click NETWORKS.
2. In the lower left-hand corner of the screen, click + NEW.



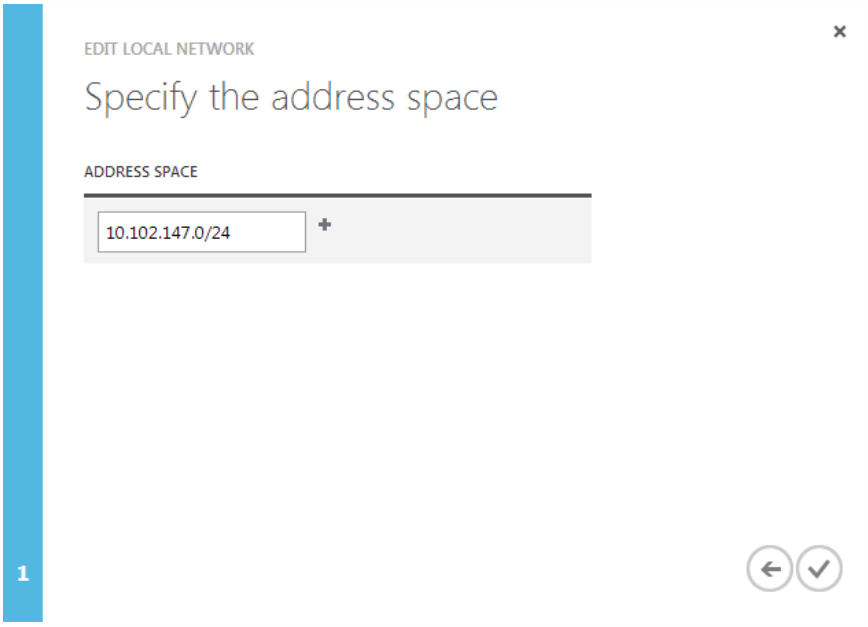
3. In the NEW navigation pane, click NETWORK, then click VIRTUAL NETWORK, and then click REGISTER LOCAL NETWORK.



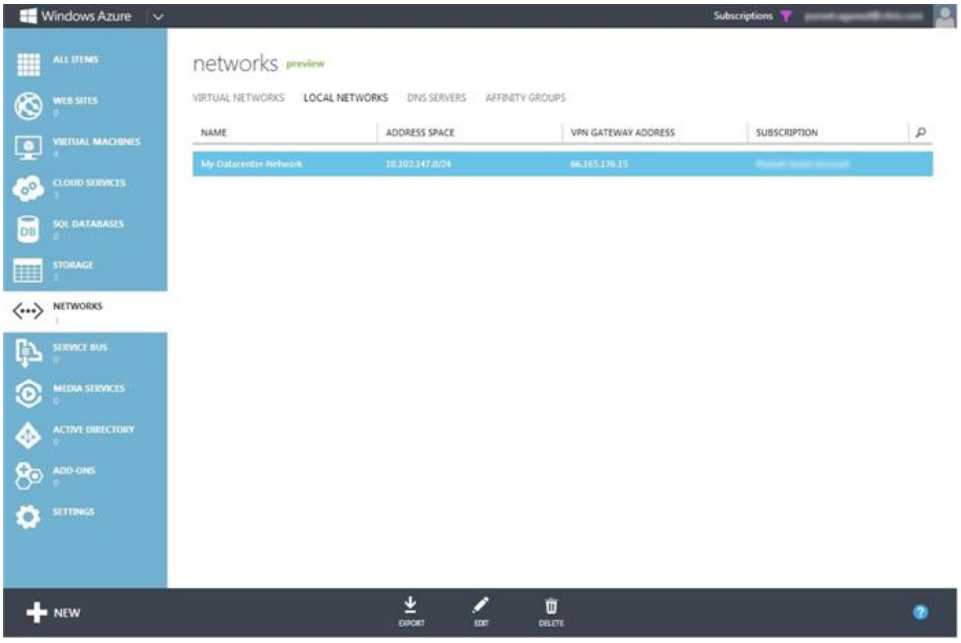
4. In the ADD A LOCAL NETWORK wizard, in the specify your local network details screen, set the following parameters:
   - NAME
   - VPN DEVICE IP ADDRESS



5. In the lower right corner of the screen, click -> (forward arrow mark).
6. On the Specify the address space screen, set the following parameter:
   - ADDRESS SPACE

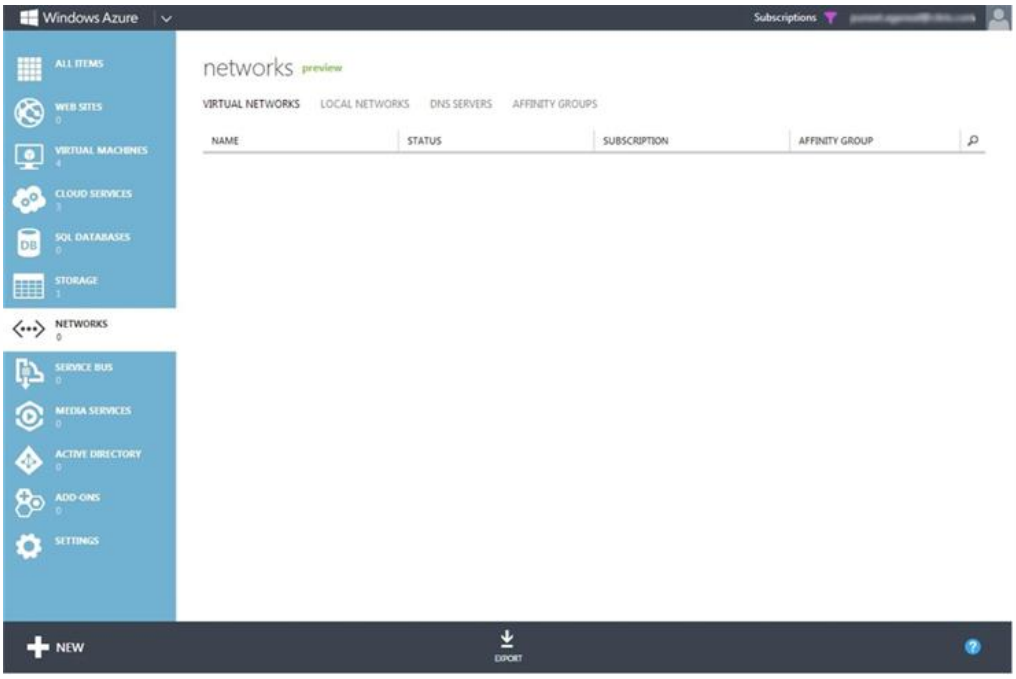


7. In the lower right corner of the screen, click the check mark.
8. The local network entity is created in Windows Azure. You can verify it on the portal's LOCAL NETWORK tab.

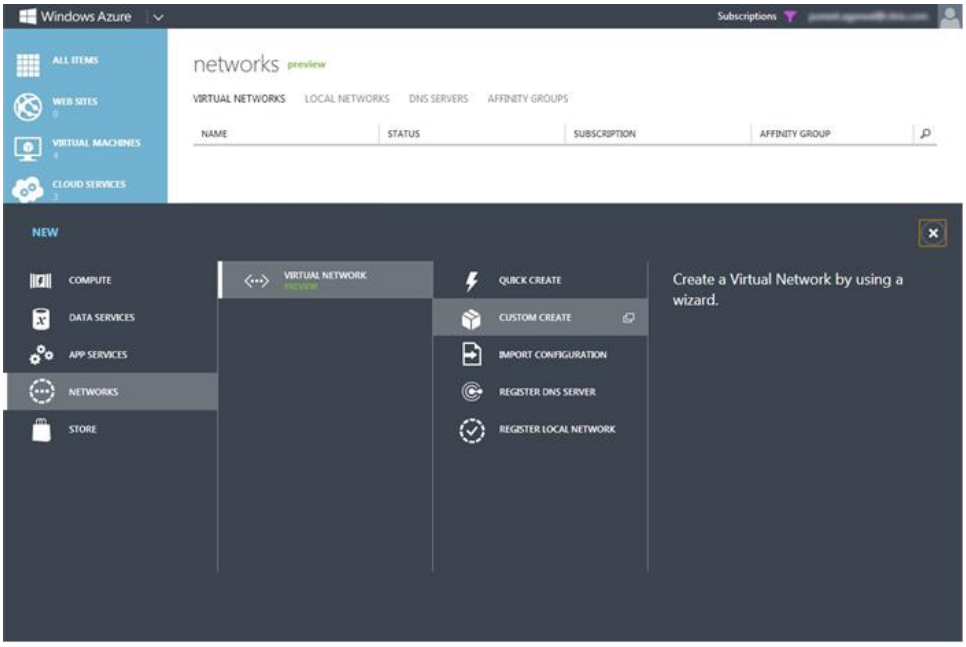


To create a virtual network in Azure by using the Microsoft Windows Azure Management Portal

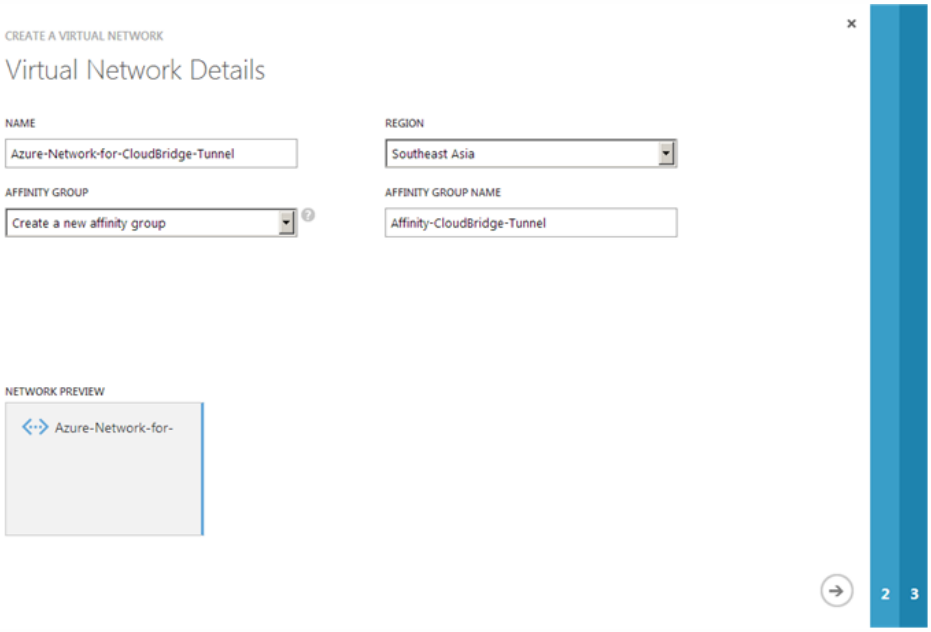
1. In the left pane, click NETWORKS.
2. In the lower left-hand corner of the screen, click + New.



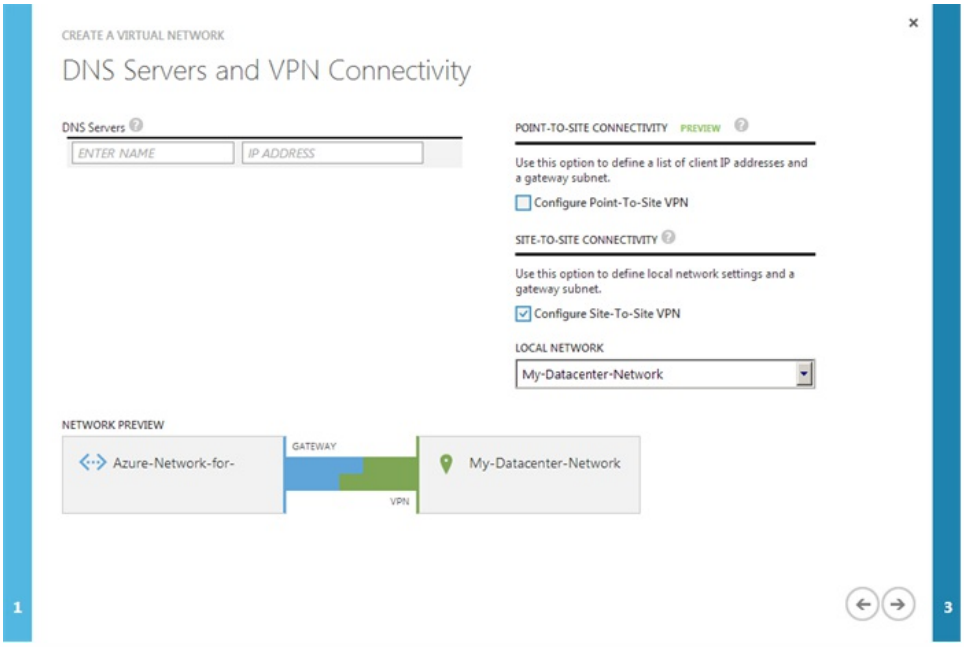
3. In the NEW navigation pane, click NETWORK, then click VIRTUAL NETWORK, and then click CUSTOM CREATE.



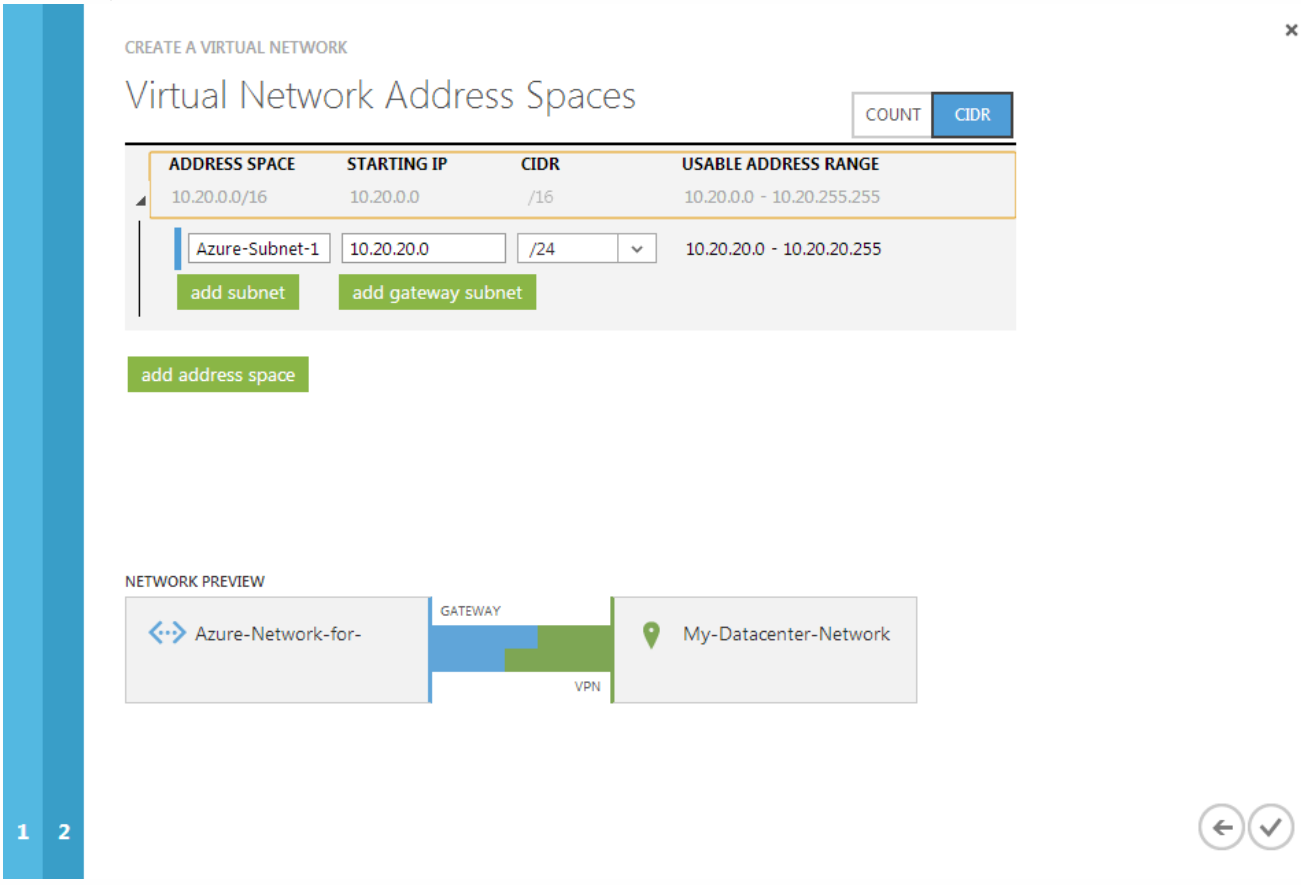
4. In the CREATE A VIRTUAL NETWORK wizard, in the Virtual Network Details screen, set the following parameters:
   - NAME
   - AFFINITY GROUP
   - REGION
   - AFFINITY GROUP NAME

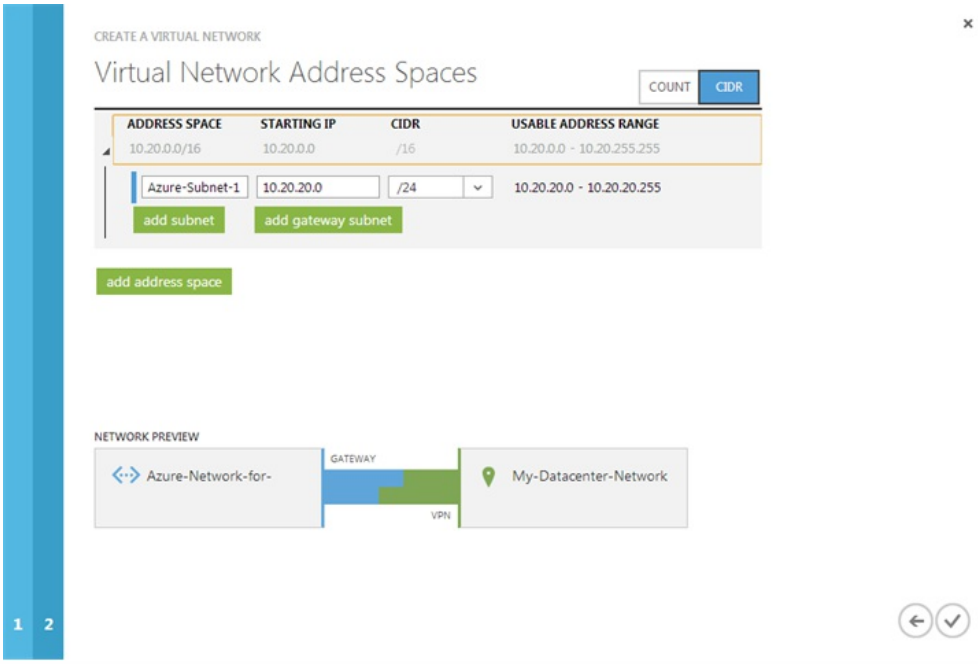


5. Click -> (forward arrow mark) in the lower right-hand corner of the screen.
6. In the DNS Servers and VPN Connectivity screen, in SITE-TO-SITE CONNECTIVITY, select Configure Site-To-Site VPN and set the following parameter:
   - LOCAL NETWORK

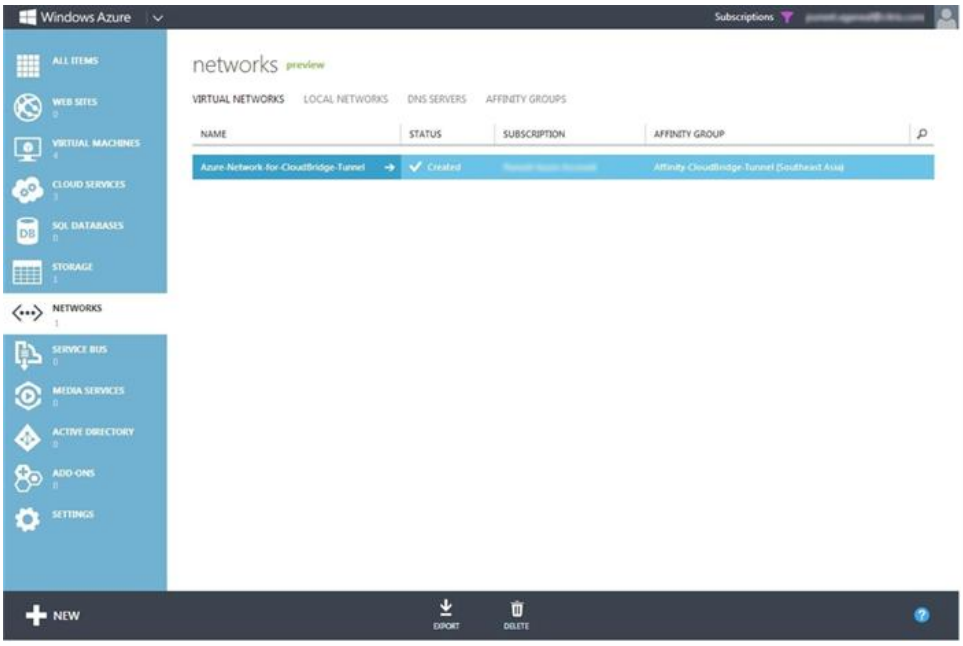


7. In the Address Space and Subnets screen, set the following parameters:
   - ADDRESS SPACE
   - SUBNETS
   - Gateway



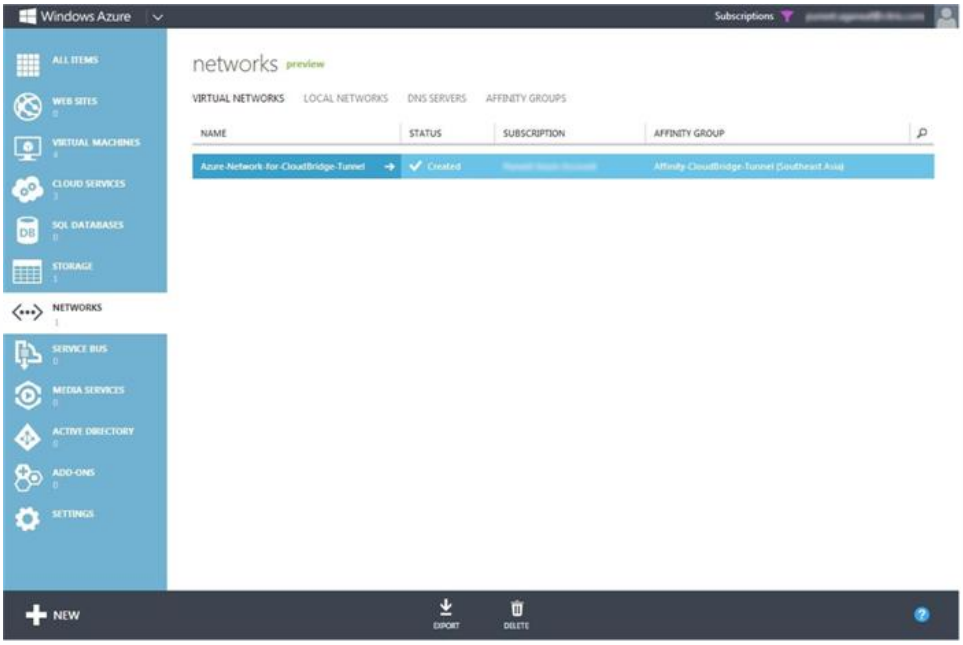


8. Click the check mark in the lower right-hand corner of the screen.
9. The virtual network is created in Windows Azure and is listed on the VIRTUAL NETWORK tab.

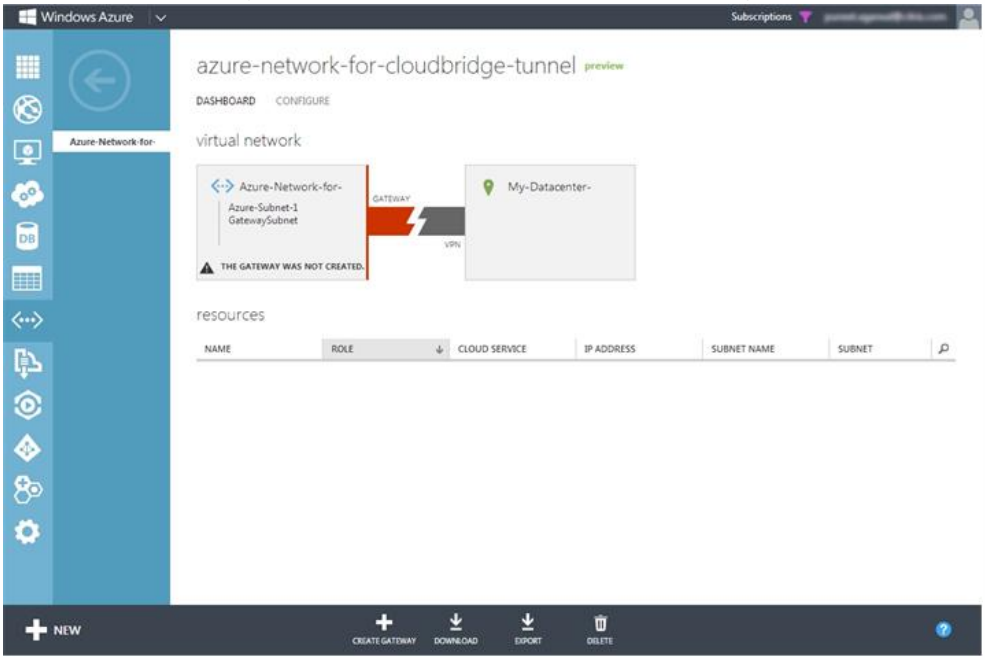


To create a gateway by using the Microsoft Windows Azure Management Portal

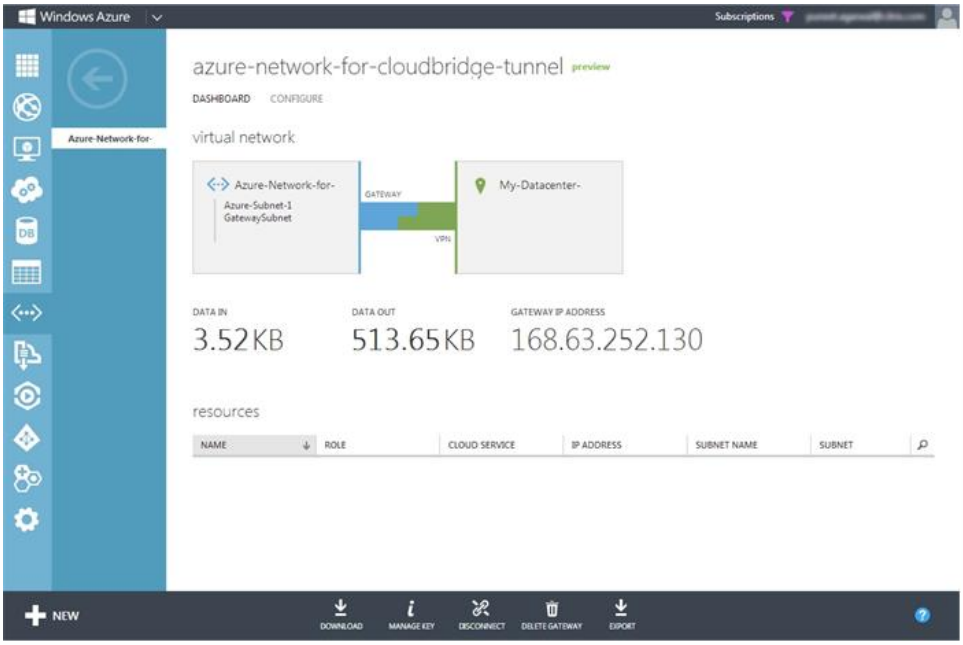
1. In the left pane, click NETWORKS.
2. On the Virtual Network tab, in the Name column, click the virtual network entity for which you want to create a gateway.



3. On the DASHBOARD page of the virtual network, at the bottom of the page, click + Create Gateway.

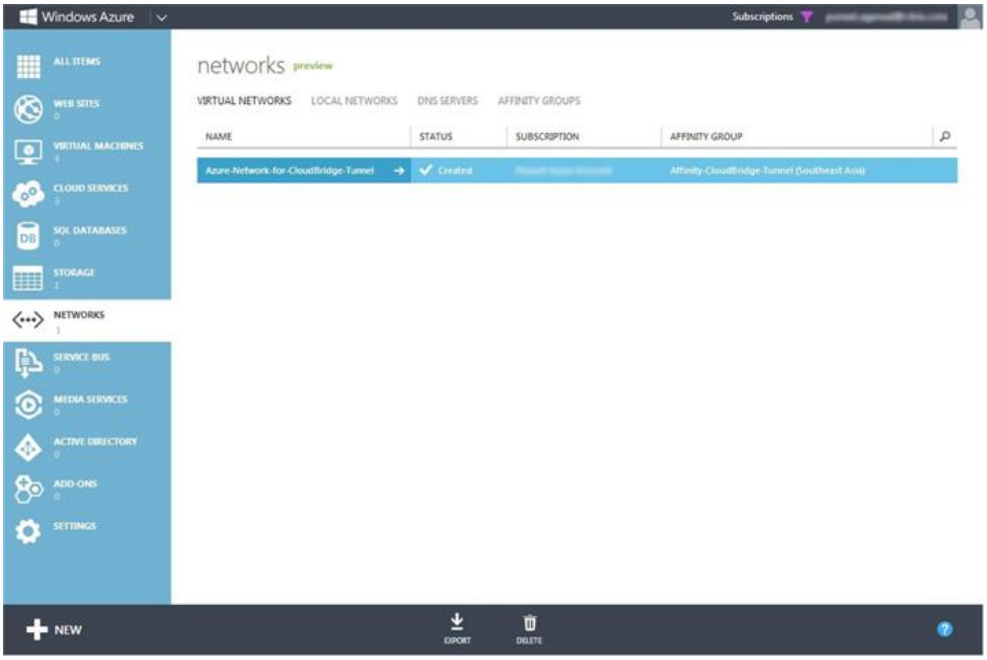


4. When prompted to confirm you want the gateway created, click YES. Creating the gateway can take up to 15 minutes.
5. When the gateway is created, the DASHBOARD page displays the gateway IP address, which is a public IP address.

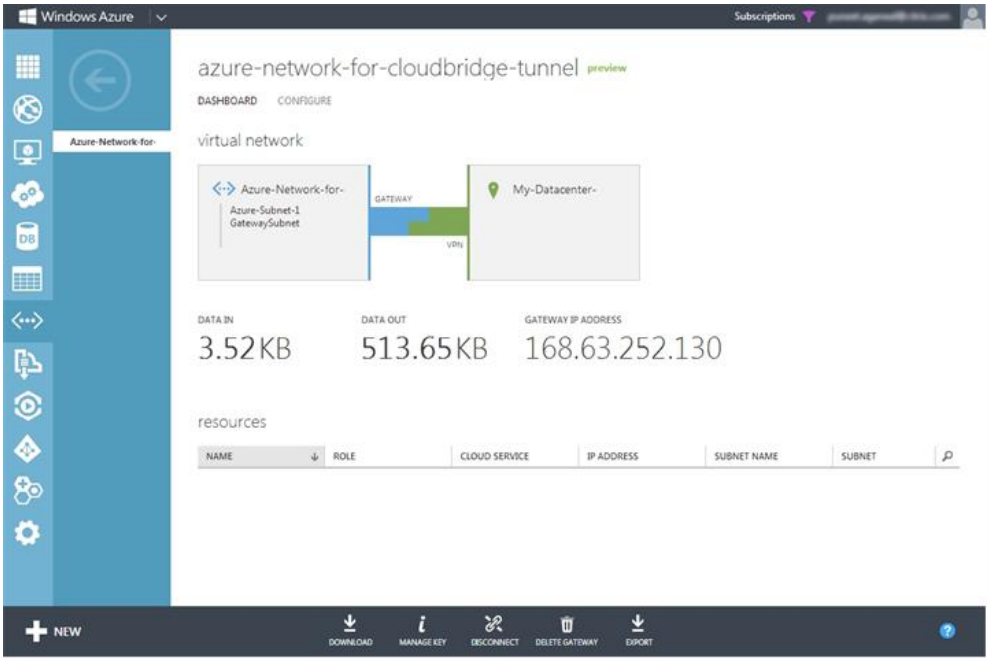


To gather public IP address of the gateway and the pre-shared key information by using the Microsoft Windows Azure Management Portal

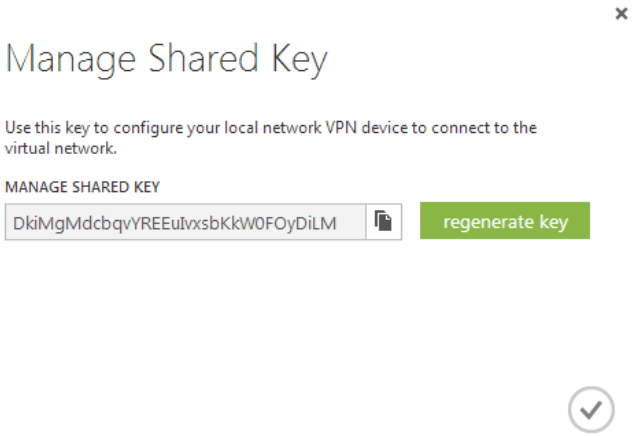
1. In the left pane, click NETWORKS.
2. On the Virtual Network tab, in the Name column, click the virtual network entity.



3. On the DASHBOARD page of the virtual network, copy the Gateway IP Address.



4. For the Pre Shared Key (PSK), at the bottom of the page, click MANAGE KEY.
5. In the MANAGE SHARED KEY dialog box, copy the SHARED KEY.



Configuring the NetScaler Appliance in the Datacenter for the CloudBridge Connector Tunnel

Updated: 2014-04-15

To configure a CloudBridge Connector tunnel between a datacenter and an Azure cloud, perform the following tasks on the NetScaler in the datacenter. You can use either the NetScaler command line or the configuration utility:

- **Create an IPSec profile**. An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and PSK, to be used by the IPSec protocol in the CloudBridge Connector tunnel.
- **Create an IP tunnel with IPSec protocol and associate the IPSec profile to it**. An IP tunnel specifies the local IP address (a public SNIP address configured on the NetScaler appliance), remote IP address (the public IP address of the gateway in Azure), protocol (IPSec) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.
- **Create a PBR rule and associate the IP tunnel to it**. A PBR entity specifies a set of conditions and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP range are the conditions for the PBR entity. You must set the source IP address range to specify the datacenter subnet whose traffic is to traverse the tunnel, and the destination IP address range to specify the Azure subnet whose traffic is to traverse the CloudBridge Connector tunnel. Any request packet originated from a client in the subnet on the datacenter and destined to a server in the subnet on the Azure cloud matches the source and destination IP range of the PBR entity. This packet is then considered for CloudBridge Connector tunnel processing and is sent across sent across the CloudBridge Connector tunnel

associated with the PBR entity.

The configuration utility combines all these tasks in a single wizard called the CloudBridge Connector wizard.

To create an IPSEC profile by using the NetScaler command line

At the Command prompt, type:

- add ipsec profile <name> -psk <string> -ikeVersion v1

To create an IPSEC tunnel and bind the IPSEC profile to it by using the NetScaler command line

At the Command prompt, type:

- add ipTunnel <name> <remote> <remoteSubnetMask> <local> -protocol IPSEC –ipsecProfileName <string>

To create a PBR rule and bind the IPSEC tunnel to it by using the NetScaler command line

At the Command prompt, type:

- add pbr <pbrName> ALLOW –srcIP <subnet-range> -destIP <subnet-range> -ipTunnel <tunnelName>
- apply pbrs

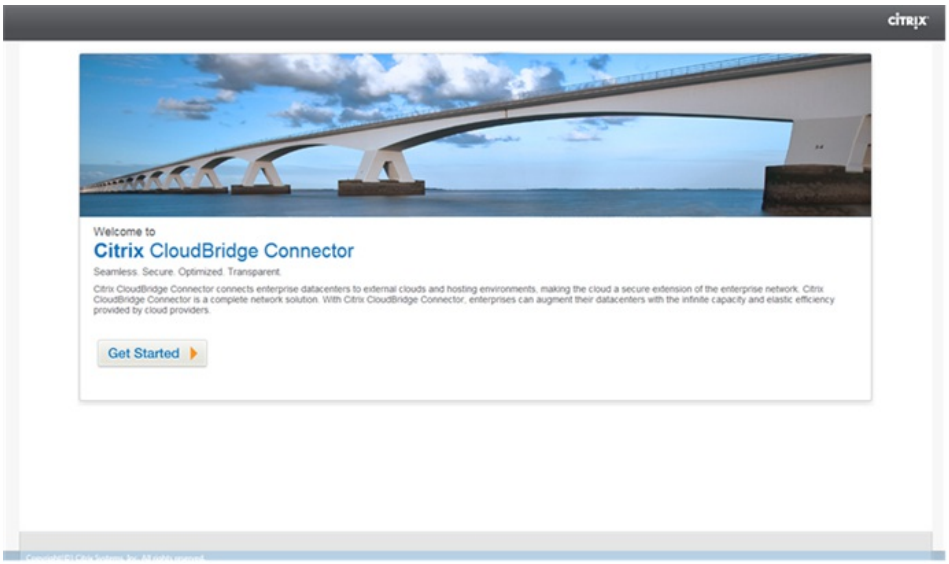
Sample Configuration

The following commands create all settings of NetScaler appliance CB_Appliance-1 used in "Example of CloudBridge Connector Configuration and Data Flow".

```
> add ipsec profile CB_Azure_IPSec_Profile -psk  DkiMgMdcbqvYREEuIvxsbKkW0FOyDiLM  -ikeVersion v1 –lifetime 31536000
Done
> add iptunnel CB_Azure_Tunnel 168.63.252.133 255.255.255.255 66.165.176.15 –protocol IPSEC –ipsecProfileName CB_Azure_IPSec_Profile
 Done
> add pbr CB_Azure_Pbr -srcIP 10.102.147.0-10.102.147.255 –destIP 10.20.0.0-10.20.255.255 –ipTunnelCB_Azure_Tunnel
 Done
> apply pbrs
Done
```

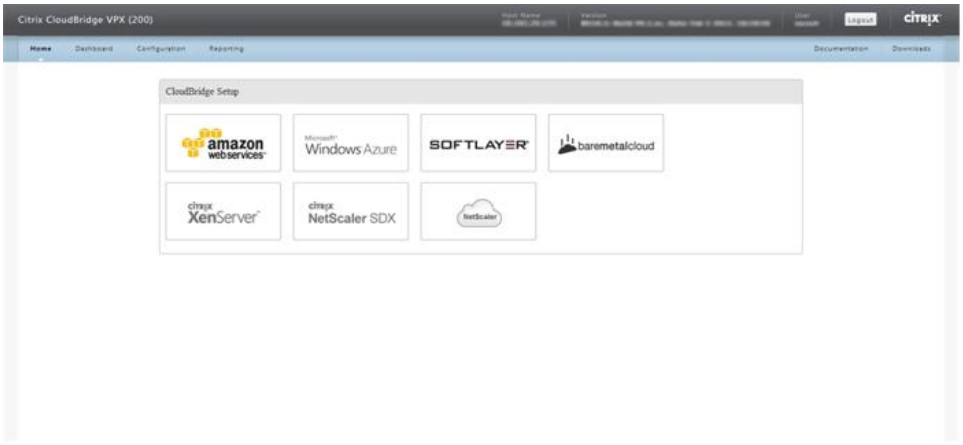
To configure a CloudBridge Connector tunnel in a NetScaler appliance by using the configuration utility

1. Access the configuration utility by using a web browser to connect to the IP address of the NetScaler appliance in the datacenter.
2. Navigate to System > CloudBridge Connector.
3. In the right pane, under Getting Started, click Create/Monitor CloudBridge.
4. Click Get Started.

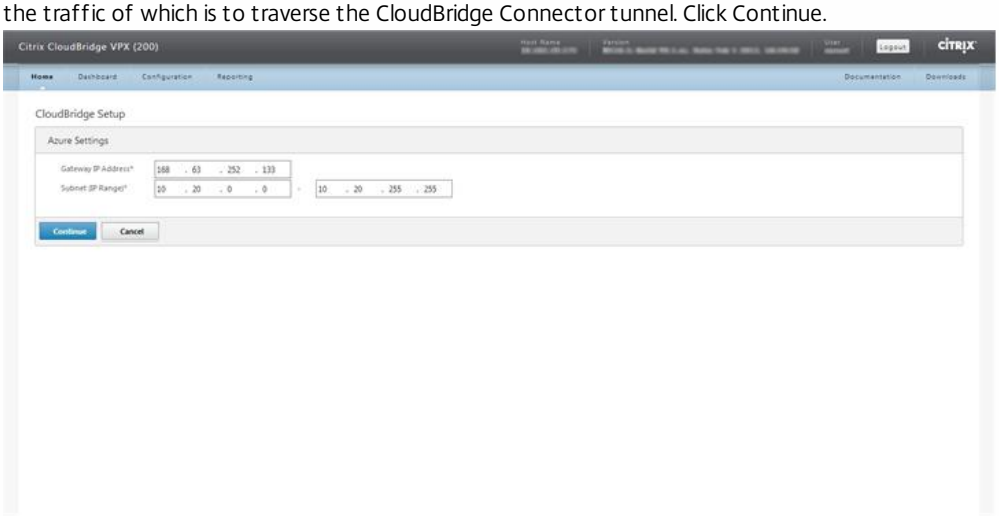


Note: If you already have any CloudBridge Connector tunnel configured on the NetScaler appliance, this screen does not appear, and you are taken to the CloudBridge Connector Setup pane.

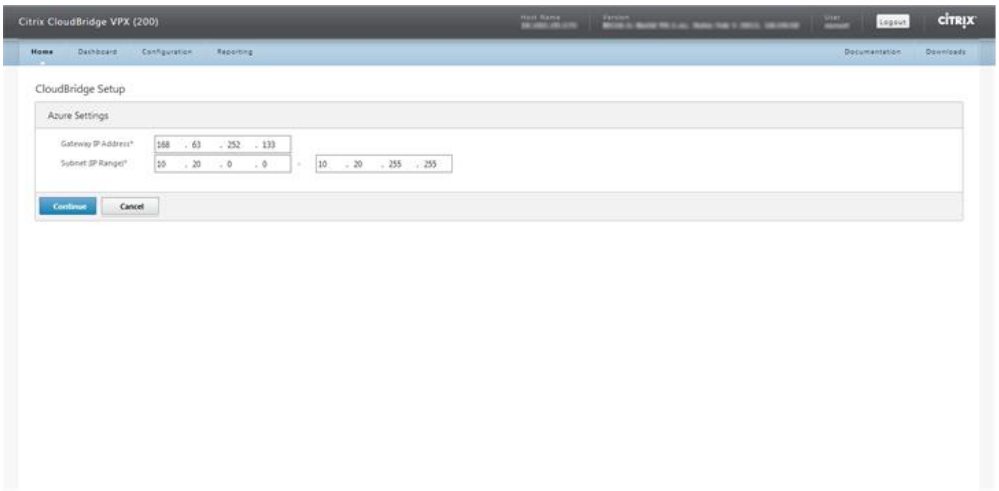
5. In the CloudBridge Setup pane, click Microsoft Windows Azure.



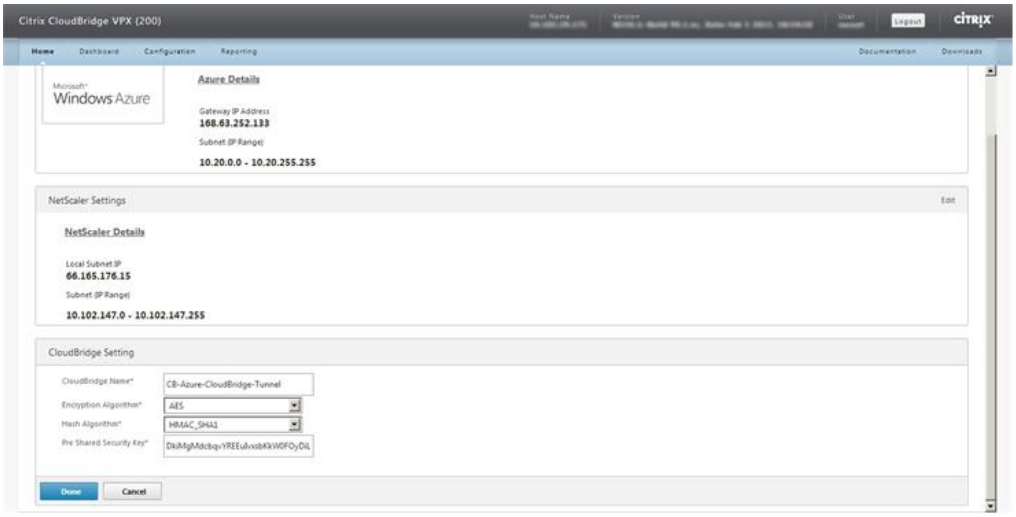
6. In the Azure Settings pane, in the Gateway IP Address* field, type the IP address of the Azure gateway. The CloudBridge Connector tunnel is then set up between the NetScaler appliance and the gateway. In the Subnet (IP Range)* text boxes, specify a subnet range (in Azure cloud), the traffic of which is to traverse the CloudBridge Connector tunnel. Click Continue.



7. In the NetScaler Settings pane, from the Local Subnet IP* drop-down list, select a publicly accessible SNIP address configured on the NetScaler appliance. In Subnet (IP Range)* text boxes, specify a local subnet range, the traffic of which is to traverse the CloudBridge Connector tunnel. Click Continue.



8. In the CloudBridge Setting pane, in the CloudBridge Name text box, type a name for the CloudBridge that you want to create.



9. From the Encryption Algorithm and Hash Algorithm drop-down lists, select the AES and HMAC_SHA1 algorithms, respectively. In the Pre Shared Security Key text box, type the security key.
10. Click Done.

Monitoring the CloudBridge Connector Tunnel

Updated: 2014-04-15

You can view statistics for monitoring the performance of a CloudBridge Connector tunnel between the NetScaler appliance in the datacenter and Microsoft Azure. To view CloudBridge Connector tunnel statistics on the NetScaler appliance, use NetScaler GUI or NetScaler command line. To view CloudBridge Connector tunnel statistics in Microsoft Azure, use the Microsoft Windows Azure Management Portal.

Displaying CloudBridge Connector tunnel Statistics in the NetScaler appliance

For information about displaying CloudBridge Connector tunnel statistics on a NetScaler appliance, see Monitoring CloudBridge Connector Tunnels.

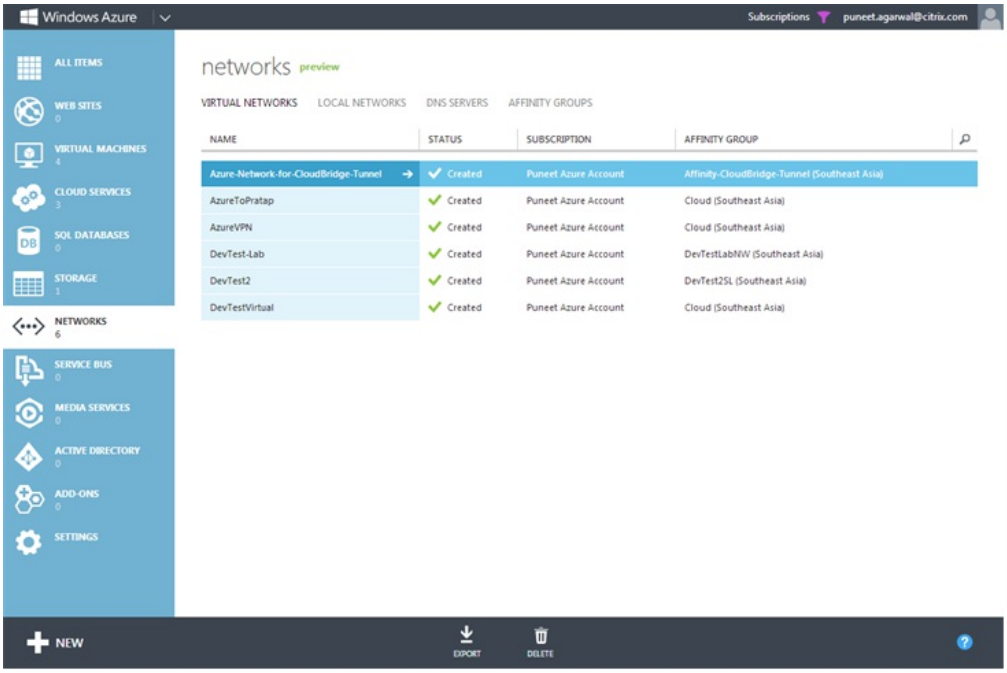
Displaying CloudBridge Connector tunnel Statistics in Microsoft Azure

The following table lists the statistical counters available for monitoring CloudBridge Connector tunnels in Microsoft Azure.

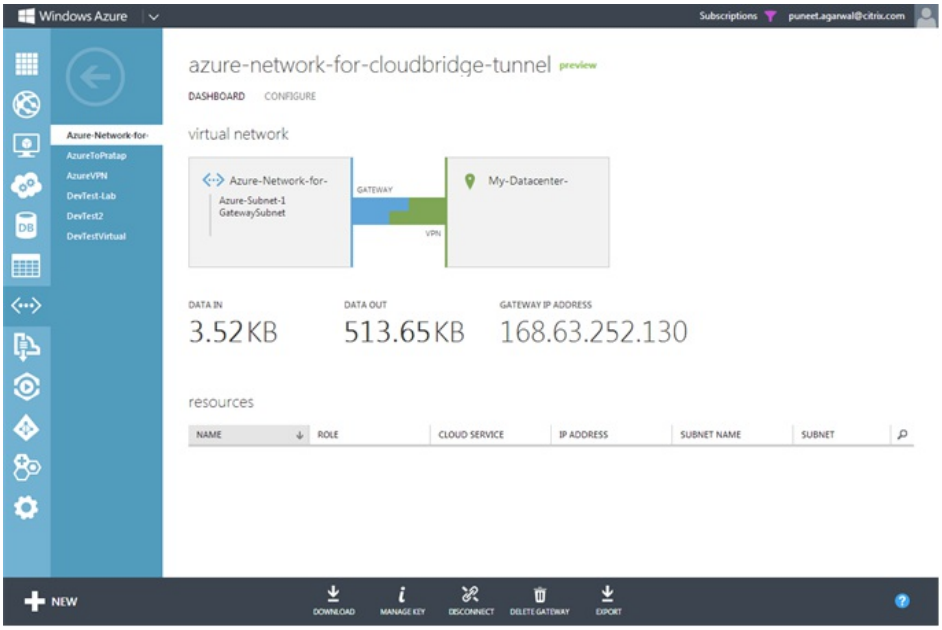
Statistical counter	Specifies
DATA IN	Total number of kilobytes received by the Azure gateway through the CloudBridge Connector tunnel since the gateway was created.
DATA OUT	Total number of kilobytes sent by the Azure gateway through the CloudBridge Connector tunnel since the gateway was created.

To display CloudBridge Connector tunnel statistics by using the Microsoft Windows Azure Management Portal

1. Log on to the Windows Azure Management Portal (https://manage.windowsazure.com/) by using your Microsoft Azure account credentials.
2. In the left pane, click NETWORKS.
3. On the Virtual Network tab, in the Name column, select the virtual network entity associated with a CloudBridge Connector tunnel whose statistics you want to display.



4. On the DASHBOARD page of the virtual network, view the DATA IN and DATA OUT counters for the CloudBridge Connector tunnel.



Configuring CloudBridge Connector Tunnel between Datacenter and SoftLayer Enterprise Cloud

Oct 12, 2016

The configuration utility includes a wizard that helps you to easily configure a CloudBridge Connector tunnel between a NetScaler appliance in a datacenter and NetScaler VPX instances on the SoftLayer enterprise cloud.

When you use the wizard of the NetScaler appliance in the datacenter, the CloudBridge Connector tunnel configuration created on the NetScaler appliance, is automatically pushed to the other endpoint or peer (the NetScaler VPX on SoftLayer) of the CloudBridge Connector tunnel.

Using the wizard of the NetScaler appliance in the datacenter, you perform the following steps to configure a CloudBridge Connector tunnel.

1. Connect to the Softlayer enterprise cloud by providing the user log on credentials.
2. Select the Citrix XenServer that is running the NetScaler VPX appliance.
3. Select the NetScaler VPX appliance.
4. Provide CloudBridge Connector tunnel parameters to:
   - Configure a GRE Tunnel.
   - Configure IPsec on the GRE tunnel.
   - Create a netbridge, which is a logical representation of the CloudBridge connector, by specifying a name.
   - Bind the GRE Tunnel to the netbridge.

To configure a CloudBridge Connector tunnel by using the configuration utility

1. Log on to the configuration utility of the NetScaler appliance in the datacenter by using your account credentials for the appliance.
2. Navigate to System > CloudBridge Connector .
3. In the right pane, under Getting Started, click Create/Monitor CloudBridge Connector.
4. Click Get Started.
   Note: If you already have any CloudBridge Connector tunnel configured on the NetScaler appliance, this screen does not appear, and you are taken to the CloudBridge Connector Setup pane.
5. In the CloudBridge Connector Setup pane, click Softlayer, and then follow the instructions in the wizard.

Monitoring the CloudBridge Connector Tunnel

You can monitor the performance of CloudBridge Connector tunnels on a NetScaler appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a NetScaler appliance, see Monitoring CloudBridge Connector Tunnels.

Configuring a CloudBridge Connector Tunnel Between a NetScaler Appliance and Cisco IOS Device

Oct 12, 2016

You can configure a CloudBridge Connector tunnel between a NetScaler appliance and a Cisco device to connect two datacenters or extend your network to a Cloud provider. The NetScaler appliance and the Cisco IOS device form the end points of the CloudBridge Connector tunnel and are called peers.

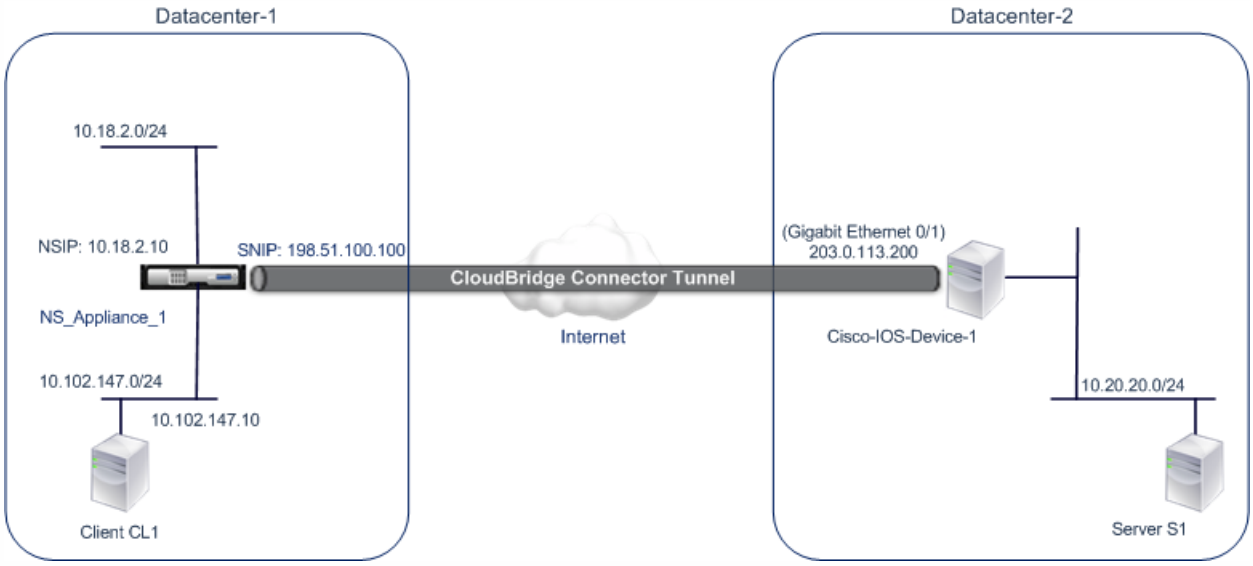
Example of CloudBridge Connector Tunnel Configuration and Data Flow

As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between the following devices:

- NetScaler appliance NS_Appliance-1 in a datacenter designated as Datacenter-1
- Cisco IOS device Cisco-IOS-Device-1 in a datacenter designated as Datacenter-2

NS_Appliance-1 and Cisco-IOS-Device-1 enable communication between private networks in Datacenter-1 and Datacenter-2 through the CloudBridge Connector tunnel. In the example, NS_Appliance-1 and Cisco-IOS-Device-1 enable communication between client CL1 in Datacenter-1 and server S1 in Datacenter-2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes IPSec profile entity NS_Cisco_IPSec_Profile, CloudBridge Connector tunnel entity NS_Cisco_Tunnel, and policy based routing (PBR) entity NS_Cisco_Pbr.



The following table lists the settings used in this example.

Entity	Name	Details

Main settings of the CloudBridge Connector tunnel setup	
IP address of the CloudBridge Connector tunnel end point (NS_Appliance-1) in Datacenter-1	198.51.100.100
IP address of the CloudBridge Connector tunnel end point (Cisco-IOS-Device-1) in Datacenter-2	203.0.113.200
Datacenter–1's subnet whose traffic is to be protected over the CloudBridge Connector tunnel	10.102.147.0/24
Datacenter–2's subnet whose traffic is to be protected over the CloudBridge Connector tunnel	10.20.20.0/24

Settings on NetScaler appliance NS_Appliance-1 in Datacenter-1		
	SNIP1(for reference purposes only)	198.51.100.100
IPSec profile	• NS_Cisco_IPSec_Profile	• IKE version: v1 • Encryption algorithm = 3DES • Hash algorithm = HMAC_SHA256 • psk = examplepresharedkey (**Note**: This is an example of a pre-share key, for illustration. Do not use this string in your CloudBridge Connector configuration)
CloudBridge Connector tunnel	NS_Cisco_Tunnel	• Remote IP = 203.0.113.200 • Local IP= 198.51.100.100 • Tunnel protocol = IPSec (IPSec in tunnel mode) • IPSec profile= NS_Cisco_IPSec_Profile
Policy based route	NS_Cisco_Pbr	• Source IP range = Subnet in the Datacenter-1=10.102.147.0-10.102.147.255 • Destination IP range = Subnet in Datacenter-2 = 10.20.20.0-10.20.20.255 • IP Tunnel = NS_Cisco_Tunnel

Settings on Cisco IOS device Cisco-IOS-Device-1 in Datacenter-2		
IKE policy		• Priority: 1 • Encryption algorithm: 3des • Hash algorithm: sha256 • Authentication: pre-share • Diffie-Hellman group identifier: 2 (1024-bit Diffie-Hellman group)
Pre-share key		• Key string: examplepresharedkey (**Note**: This is an example of a pre-share key, for illustration. Do not use this string in your CloudBridge Connector configuration) • Peer address: 198.51.100.100 (IP address of type SNIP configured on NS_Appliance-1)
Crypto IPSec Transform Set	NS-CISCO-TS	• ESP Authentication: esp-sha256-hmac • ESP Encryption Algorithm: esp-3des • Mode: tunnel
Crypto access list	111	• Source: 10.20.20.0 (Subnet in the Datacenter-1) • Source wildcard: 0.0.0.255 • Destination: 10.102.147.0 (Subnet in the Datacenter-2) • Destination Wildcard: 0.0.0.255
Crypto Map	NS-CISCO-CM	• Peer address: 198.51.100.100 (IP address of type SNIP configured on NS_Appliance-1) • Crypto access list: 111 • Crypto transform set: NS-CISCO-TS
Associated Interface for the CloudBridge Connector tunnel	Gigabit Ethernet 0/1	• IP address: 203.0.113.200 • Crypto map: NS-CISCO-CM

Points to Consider for a CloudBridge Connector Tunnel Configuration

Before configuring a CloudBridge Connector tunnel between a NetScaler appliance and a Cisco IOS device, consider the following points:

- The following IPSec settings are supported for a CloudBridge Connector tunnel between a NetScaler appliance and a Cisco IOS device.

IPSec Properties	**Setting**
IPSec mode	Tunnel mode
IKE version	Version 1
IKE authentication method	Pre-Shared Key
IKE encryption algorithm	• AES • 3DES
IKE hash algorithm	• HMAC SHA1 • HMAC SHA256 • HMAC SHA384 • HMAC SHA512 • HMAC MD5
ESP encryption algorithm	• AES • 3DES
ESP hash algorithm	• HMAC SHA1 • HMAC SHA256 • HMAC SHA256 • HMAC SHA256 • HMAC MD5

- You must specify the same IPSec settings on the NetScaler appliance and the Cisco IOS device at the two ends of the CloudBridge Connector.
- NetScaler provides a common parameter (in IPSec profiles) for specifying an IKE hash algorithm and an ESP hash

algorithm. It also provides another, and a common parameter for specifying an IKE encryption algorithm and an ESP encryption algorithm. Therefore on the Cisco device, you must specify the same hash algorithm and same encryption algorithm for IKE (while creating IKE policy) and ESP (while creating IPSec transform set).

- You must configure the firewall at the NetScaler end and Cisco device end to allow the following.
  - Any UDP packets for port 500
  - Any UDP packets for port 4500
  - Any ESP (IP protocol number 50) packets

Configuring Cisco IOS device for the CloudBridge Connector Tunnel

To configure a CloudBridge Connector tunnel on a Cisco IOS device, use the Cisco IOS command line interface, which is the primary user interface for configuring, monitoring, and maintaining Cisco devices.

Before you begin the CloudBridge Connector tunnel configuration on a Cisco IOS device, make sure that:

- You have a user account with administrator credentials on the Cisco IOS device.
- You are familiar with the Cisco IOS command line interface.
- The Cisco IOS device is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.

Note: The procedures for configuring CloudBridge Connector tunnel on a Cisco IOS device might change over time, depending on the Cisco release cycle. Citrix recommends that you follow the official Cisco product documention for Configuring IPSec VPN tunnels, at:

- http://www.cisco.com

To configure a CloudBridge connector tunnel between a NetScaler appliance and a Cisco IOS device, perform the following tasks on the Cisco device's IOS command line:

- **Create an IKE Policy**. An IKE policy defines a combination of security parameters to be used during the IKE negotiation. For example, parameters such as hash algorithm, encryption algorithm, Diffie-Hellman group, and authentication method to be used in the IKE negotiation are set in this task.
- **Configure a Pre-shared key for IKE authentication**. A pre-shared key is a text string, which the peers of a CloudBridge Connector tunnel use to mutually authenticate with each other. The pre-shared keys are matched against each other for IKE authentication. Therefore, for the authentication to be successful, you must configure the same pre-shared key on the Cisco device and the NetScaler appliance.
- **Define a transform set and configure IPSec in tunnel mode**. A transform set defines a combination of security parameters to be used in the exchange of data over the CloudBridge Connector tunnel after the IKE negotiation is successful. Parameters such as hash algorithm and encryption algorithm are set in this task. This task also specifies that IPSec in tunnel mode be used for the CloudBridge tunnel.
- **Create a crypto access List**. Crypto access lists are used to define the subnets whose IP traffic will be protected over the CloudBridge tunnel. The source and destination parameters in the access list specify the Cisco device side and NetScaler side subnets that are to be protected over the CloudBridge Connector Tunnel. The access list must be set to permit. Any request packet that originates from a device in the Cisco device side subnet and is destined to a device in the NetScaler side subnet, and that matches the source and destination parameters of the access list, is sent across the

CloudBridge Connector tunnel.

- **Create a crypto map**. Crypto maps define the IPSec parameters to be negotiated with peer. They include the following: Crypto access list to identify the subnets whose traffic is to be protected over the CloudBridge tunnel, peer (NetScaler) identification by IP address, and transform set to match the peer security settings.
- **Apply the crypto Map to an interface**. In this task, you apply a crypto map to an interface through which CloudBridge Connector tunnel traffic will flow. Applying the crypto map to an interface instructs the Cisco IOS device to evaluate all the interface traffic against the crypto map set, and to use the specified policy during connection or SA negotiation on behalf of subnet's traffic to be protected.

The examples in the following procedures create settings of Cisco IOS device Cisco-IOS-Device-1 used in "Example of CloudBridge Connector Configuration and Data Flow."

To create an IKE policy by using the Cisco IOS command line

At the Cisco IOS device's command prompt, type the following commands, starting in global configuration mode, in the order shown:

Command	Example	Command Description
crypto isakmp policy *priority*	Cisco-ios-device-1(config)# crypto isakmp policy 1	Enter config-isakmp command mode and identify the policy to create. (Each policy is uniquely identified by the priority number you assign.) This example configures policy 1.
encryption (**3des** | **aes**)	Cisco-ios-device-1 (config-isakmp)# **encryption 3des**	Specify the encryption algorithm. This example configures the 3DES algorithm.
hash (**sha** | **sha256** | **sha384** | **md5**)	Cisco-ios-device-1 (config-isakmp)# **hash sha256**	Specify the hash algorithm. This example configures SHA256.
authentication pre-share	Cisco-ios-device-1 (config-isakmp)# **authentication pre-share**	Specify the pre-share authentication method. **Note**: RSA encrypted nonces (**rsa-encr**), RSA signatures (**rsa-sig**), and digital certificate authentication methods are not supported.
group 2	Cisco-ios-device-1 (config-isakmp)# **group 1**	Specify 1024-bit Diffie-Hellman group identifier (**2**).

lifetime seconds	Cisco-ios-device-1 (config-isakmp)# **lifetime 86400**	Specify the security association's lifetime in seconds. This example configures 86400 seconds (one day).
exit	Cisco-ios-device-1 (config-isakmp)# **exit** Cisco-ios-device-1 (config)#	Exit back to global configuration mode.

To configure a pre-shared key by using the Cisco IOS command line

At the Cisco IOS device's command prompt, type the following commands, starting in global configuration mode, in the order shown:

Command	Example	Command Description
crypto isakmp identity address	Cisco-ios-device-1(config)# **crypto isakmp identity address**	Specify the ISAKMP identity (**address**) for the Cisco IOS device to use when communicating with the peer (NetScaler appliance) during IKE negotiations. This example specifies the **address** keyword, which uses IP address 203.0.113.200 (Gigabit Ethernet interface **0/1** of Cisco-IOS-Device-1) as the identity for the device.
crypto isakmp key *keystring* **address** *peer-address*	Cisco-ios-device-1 (config)# **crypto isakmp key examplepresharedkey address 198.51.100.100**	Specify a pre-shared key for the IKE authentication. This example configures shared key examplepresharedkey to be used with the NetScaler appliance NS_Appliance-1 (198.51.100.100). The same pre-shared key must be configured on the NetScaler appliance for IKE authentication to be successful between the Cisco IOS device and the NetScaler appliance.

To create a crypto access list by using the Cisco IOS command line

At the Cisco IOS device's command prompt, type the following command in global configuration mode, in the order shown:

Command	Example	Command Description
access-list *access-list-number* **permit**	Cisco-ios-device-1(config)# **access-list 111 permit ip 10.20.20.0 0.0.0.255 10.102.147.0 0.0.0.255**	Specify conditions to determine the subnets whose IP traffic is to be protected over the CloudBridge Connector tunnel.

IP *source source-wildcard destination destination-wildcard*		This example configures access list 111 to protect traffic from subnets 10.20.20.0/24 (at the Cisco-IOS-Device-1 side) and 10.102.147.0/24 (at the NS_Appliance-1 side).

To define a transform and configure IPSec tunnel mode by using the Cisco IOS command line

At the Cisco IOS device's command prompt, type the following commands, starting in global configuration mode, in the order shown:

Command	Example	Command Description
crypto ipsec transform-set *name ESP_Authentication _Transform ESP_Encryption_Transform* **Note**: *ESP_Authentication _Transform* can take the following values: • esp-sha-hmac • esp-sha256-hmac • esp-sha384-hmac • esp-sha512-hmac • esp-md5-hmac *ESP_Encryption_Transform* can take the following values: • esp-aes • esp-3des	Cisco-ios-device-1(config)# **crypto ipsec transform-set NS-CISCO-TS esp-sha256-hmac esp-3des**	Define a transform set and specify the ESP hash algorithm (for authentication) and the ESP encryption algorithm to be used during exchange of data between the CloudBridge Connector tunnel peers. This example defines transform set NS-CISCO-TS and specifies ESP authentication algorithm as esp-sha256-hmac, and ESP encryption algorithm as esp-3des.
mode tunnel	Cisco-ios-device-1 (config-crypto-trans)# **mode tunnel**	Set IPSec in tunnel mode.

exit	Cisco-ios-device-1 (config-crypto-trans)# **exit** Cisco-ios-device-1 (config)#	Exit back to global configuration mode.

To create a crypto map by using the Cisco IOS command line

At the Cisco IOS device's command prompt, type the following commands starting in global configuration mode, in the order shown:

Command	Example	Command Description
crypto map *map-name seq-num* **ipsec-isakmp**	Cisco-ios-device-1 (config)# **crypto map NS-CISCO-CM 2 ipsec-isakmp**	Enter crypto map configuration mode, specify a sequence number for the crypto map, and configure the crypto map to use IKE to establish security associations (SAs). This example configures sequence number 2 and IKE for crypto map NS-CISCO-CM.
set peer *ip-address*	Cisco-ios-device-1 (config-crypto-map)# **set peer 172.23.2.7**	Specify the peer (NetScaler appliance) by its IP address. This example specifies 198.51.100.100, which is the CloudBridge Connector endpoint IP address on the NetScaler appliance.
match address *access-list-id*	Cisco-ios-device-1 (config-crypto-map)# **match address 111**	Specify an extended access list. This access list specifies conditions to determine the subnets whose IP traffic is to be protected over the CloudBridge Connector tunnel. This example specifies access list 111.
set transform-set *transform-set-name*	Cisco-ios-device-1 (config-crypto-map)# **set transform-set NS-CISCO-TS**	Specify which transform sets are allowed for this crypto map entry. This example specifies transform set NS-CISCO-TS.
exit	Cisco-ios-device-1 (config-	Exit back to global configuration mode.

	crypto-map)# **exit** Cisco-ios-device-1 (config)#	

To apply a crypto map to an interface by using the Cisco IOS command line

At the Cisco IOS device's command prompt, type the following commands starting in global configuration mode, in the order shown:

Command	Example	Command Description
interface *interface-ID*	Cisco-ios-device-1(config)# **interface GigabitEthernet 0/1**	Specify a physical interface to which to apply the crypto map and enter interface configuration mode. This example specifies Gigabit Ethernet interface 0/1 of the Cisco device Cisco-IOS-Device-1. IP address 203.0.113.200 is already set to this interface.
crypto map *map-name*	Cisco-ios-device-1 (config-if)# **crypto map NS-CISCO-CM**	Apply the crypto map to the physical interface. This example applies crypto map NS-CISCO-CM.
exit	Cisco-ios-device-1 (config-if)# **exit** Cisco-ios-device-1 (config)#	Exit back to global configuration mode.

Configuring the NetScaler Appliance for the CloudBridge Connector Tunnel

To configure a CloudBridge Connector tunnel between a NetScaler appliance and a Cisco IOS device, perform the following tasks on the NetScaler appliance. You can use either the NetScaler command line or the NetScaler graphical user interface (GUI):

- **Create an IPSec profile**. An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and authentication method (Pre-Shared key) to be used by the IPSec protocol in the

CloudBridge Connector tunnel.

- **Create an IP tunnel that uses IPSec protocol, and associate the IPSec profile with it**. An IP tunnel specifies the local IP address (CloudBridge Connector tunnel end point IP address (of type SNIP) configured on the NetScaler appliance), remote IP address (CloudBridge Connector tunnel endpoint IP address configured on the Cisco IOS device), protocol (IPSec) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.
- **Create a PBR rule and associate it with the IP tunnel**. A PBR entity specifies a set of rules and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP address range are the conditions for the PBR entity. Set the source IP address range to specify the NetScaler-side subnet whose traffic is to be protected over the tunnel, and set the destination IP address range to specify the Cisco IOS device side subnet whose traffic is to be protected over the tunnel. Any request packet that originates from a client in the subnet on the NetScaler side and is destined to a server in the Cisco IOS device side subnet, and matches the source and destination IP range of the PBR entity, is sent across the CloudBridge Connector tunnel associated with the PBR entity. Apply the PBR rule to make it functional.

To create an IPSEC profile by using the NetScaler command line

At the Command prompt, type:

- **add ipsec profile** <name> -**psk** <string> -**ikeVersion** v1
- **show ipsec profile** <name>

To create an IPSEC tunnel and bind the IPSEC profile to it by using the NetScaler command line

At the Command prompt, type:

- **add ipTunnel** <name> <remote> <remoteSubnetMask> <local> -**protocol** IPSEC –**ipsecProfileName** <string>
- **add ipTunnel** <name>

To create a PBR rule and bind the IPSEC tunnel to it by using the NetScaler command line

At the Command prompt, type:

- **add pbr** <pbrName> ALLOW –**srcIP** <subnet-range> -**destIP** <subnet-range> -**ipTunnel** <tunnelName>
- **apply pbrs**
- **show pbrs** <pbrName>

Sample Configuration COPY

```
The following commands create settings of NetScaler appliance NS_Appliance-1 in "Example of CloudBridge Connector Configuration an

>  add ipsec profile NS_Cisco_IPSec_Profile -psk  examplepresharedkey -ikeVersion v1 –lifetime 315360 –encAlgo 3DES

Done

>  add iptunnel NS_Cisco_Tunnel 203.0.113.200 255.255.255.255 198.51.100.100 –protocol IPSEC –ipsecProfileName NS_Cisco_IPSec

Done

> add pbr NS_Cisco_Pbr -srcIP 10.102.147.0-10.102.147.255 –destIP 10.20.0.0-10.20.255.255 –ipTunnel NS_Cisco_Tunnel

Done

> apply pbrs

Done
```

To create an IPSEC profile by using the NetScaler GUI

1. Navigate to **System** > **CloudBridge Connector** > **IPSec Profile**.
2. In the details pane, click **Add**.
3. In the **Add IPSec Profile** dialog box, set the following parameters:
   - Name
   - Encryption Algorithm
   - Hash Algorithm
   - IKE Protocol Version
4. Configure the **IPSec authentication** method to be used by the two CloudBridge Connector tunnel peers to mutually authenticate: Select the **Pre-shared key authentication** method and set the **Pre-Shared Key Exists** parameter.
5. Click **Create**, and then click **Close**.

To create an IP tunnel and bind the IPSEC profile to it by using the NetScaler GUI

1. Navigate to **System** > **CloudBridge Connector** > **IP Tunnels**.
2. On the **IPv4 Tunnels** tab, click **Add**.
3. In the **Add IP Tunnel** dialog box, set the following parameters:
   - Name
   - Remote IP
   - Remote Mask
   - Local IP Type (In the Local IP Type drop down list, select Subnet IP).
   - Local IP (All the configured IPs of the selected IP type are in the Local IP drop down list. Select the desired IP from the list.)

- Protocol
- IPSec Profile

4. Click **Create**, and then click **Close**.

To create a PBR rule and bind the IPSEC tunnel to it by using the NetScaler GUI

1. Navigate to **System** > **Network** > **PBR**.
2. On the **PBR** tab, click **Add**.
3. In the **Create PBR** dialog box, set the following parameters:
   - Name
   - Action
   - Next Hop Type (Select IP Tunnel)
   - IP Tunnel Name
   - Source IP Low
   - Source IP High
   - Destination IP Low
   - Destination IP High
4. Click **Create**, and then click **Close**.

To apply a PBR by using the NetScaler GUI

1. Navigate to **System** > **Network** > **PBRs**.
2. On the **PBRs** tab, select the **PBR**, in the **Action list**, select **Apply**.

The corresponding new CloudBridge Connector tunnel configuration on the NetScaler appliance appears in the configuration utility. The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Connector pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

Monitoring the CloudBridge Connector Tunnel

You can monitor the performance of CloudBridge Connector tunnels on a NetScaler appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a NetScaler appliance, see Monitoring CloudBridge Connector Tunnels.

Configuring a CloudBridge Connector Tunnel Between a NetScaler Appliance and Fortinet FortiGate Appliance

Jan 19, 2017

You can configure a CloudBridge Connector tunnel between a Citrix NetScaler appliance and a Fortinet FortiGate appliance to connect two datacenters or extend your network to a cloud provider. The NetScaler appliance and the FortiGate appliance form the end points of the CloudBridge Connector tunnel and are called peers.

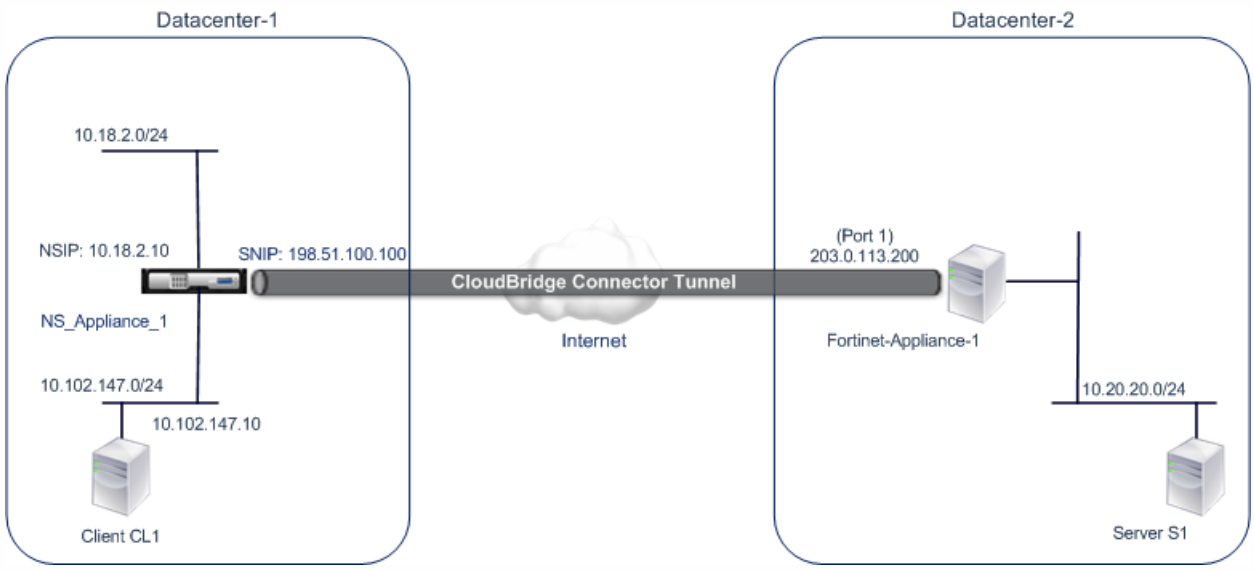
Example of a CloudBridge Connector Tunnel Configuration

As an illustration of the traffic flow in a CloudBridge Connector tunnel, consider an example in which a CloudBridge Connector tunnel is set up between the following devices:

- NetScaler appliance NS_Appliance-1 in a datacenter designated as Datacenter-1
- FortiGate appliance FortiGate-Appliance-1 in a datacenter designated as Datacenter-2

NS_Appliance-1 and FortiGate-Appliance-1 enable communication between private networks in Datacenter-1 and Datacenter-2 through the CloudBridge Connector tunnel. In the example, NS_Appliance-1 and FortiGate-Appliance-1 enable communication between client CL1 in Datacenter-1 and server S1 in Datacenter-2 through the CloudBridge Connector tunnel. Client CL1 and server S1 are on different private networks.

On NS_Appliance-1, the CloudBridge Connector tunnel configuration includes IPSec profile entity NS_Fortinet_IPSec_Profile, CloudBridge Connector tunnel entity NS_Fortinet_Tunnel, and policy based routing (PBR) entity NS_Fortinet_Pbr.



The following table lists the settings used in this example.

Entity	Name	Details
Main settings of the CloudBridge Connector tunnel setup		

IP address of the CloudBridge Connector tunnel end point (NS_Appliance-1) in Datacenter-1		• 198.51.100.100
IP address of the CloudBridge Connector tunnel end point (FortiGate-Appliance-1) in Datacenter-2		• 203.0.113.200
Datacenter–1's subnet whose traffic is to be protected over the CloudBridge Connector tunnel		• 10.102.147.0/24
Datacenter–2's subnet whose traffic is to be protected over the CloudBridge Connector tunnel		• 10.20.20.0/24
Settings on NetScaler appliance NS_Appliance-1 in Datacenter-1		
	SNIP1(for reference purposes only)	• 198.51.100.100
IPSec profile	NS_Fortinet_IPSec_Profile	• IKE version: v1 • Encryption algorithm: AES • Hash algorithm: HMAC_SHA1 • psk = examplepresharedkey (Note: This is an example of a pre-share key, for illustration. Citrix does not recommend to use this string in your CloudBridge Connector configuration)
CloudBridge Connector tunnel	NS_Fortinet_Tunnel	• Remote IP = 203.0.113.200 • Local IP= 198.51.100.100 • Tunnel protocol = IPSEC • IPSec profile= NS_Fortinet_IPSec_Profile
Policy based route	NS_Fortinet_Pbr	• Source IP range = Subnet in the Datacenter-1=10.102.147.0-10.102.147.255 • Destination IP range =Subnet in Datacenter-2=10.20.20.0-10.20.20.255 • IP Tunnel = NS_Fortinet_Tunnel

Settings on Fortinet FortiGate-Appliance-1 in Datacenter-2		

Phase 1 Configuration	P1-NETSCALER-TUNNEL	• Remote Gateway: Static IP Address
		• IP Address: 198.51.100.100
		• Local Interface: port1
		• Mode: Main (ID Protection)
		• Authentication Method: Preshared Key
		• Pre-Shared Key: examplepresharedkey
		• Enable IPSec Interface Mode: Disabled
		• IKE Version: 1
		• P1 Proposal
		  • 1- Encrytion: AES
		  • Authentication: HMAC_SHA1
		• DH Group: 2
		• XAUTH: Disabled
		• Dead Peer Detection: Enabled

Phase 2 Configuration	P2-NETSCALER-TUNNEL	• Phase 1: P1-NETSCALER-FORTIGATE
		• P2 Proposal
		  • 1- Encrytion: AES
		  • Authentication: HMAC_SHA1
		  • Enable replay detection: Enabled
		  • Enable perfect forward secrecy (PFS): Enabled
		• DH Group: 2
		• Auto Key Keep Alive: Enabled
		• Auto-Negotiate: Enabled
		• Quick Selector Mode
		  • Source address: FORTINET-SIDE-SUBNET
		  • Source port: 0
		  • Destination address: NETSCALER-SIDE-SUBNET
		  • Destination port: 0
		  • Protocol: 0

Policy Addresses		• FORTINET-SIDE-SUBNET
		  • Subnet / IP Range: 10.20.20.0/255.255.255.0
		  • Interface: port2
		• NETSCALER-SIDE-SUBNET
		  • Subnet / IP Range: 10.102.147.0/255.255.255.0
		  • Interface: port1

		• Policy Type: VPN

IPSec Security Policy		• Policy Subtype: IPsec
		• Local Interface: port2
		• Local Protected Subnet: FORTINET-SIDE-SUBNET
		• Outgoing VPN Interface: port1
		• Remote Protected Subnet: NETSCALER-SIDE-SUBNET
		• VPN Tunnel
		  • Use Existing: Enabled
		  • VPN Tunnel: P1-NETSCALER-FORTIGATE
		  • Allow traffic to be initiated from the remote side: Enabled

Points to Consider for a CloudBridge Connector Tunnel Configuration

- The following IPSec settings are supported for a CloudBridge Connector tunnel between a NetScaler appliance and a FortiGate appliance.

IPSec Properties	**Setting**
IPSec mode	Tunnel mode
IKE version	Version 1
IKE authentication method	Pre-Shared Key
IKE encryption algorithm	AES
IKE hash algorithm	HMAC SHA1
ESP encryption algorithm	AES
ESP hash algorithm	HMAC SHA1

- You must specify the same IPSec settings on the NetScaler appliance and the FortiGate appliance at the two ends of the CloudBridge Connector.
- NetScaler provides a common parameter (in IPSec profiles) for specifying an IKE hash algorithm and an ESP hash algorithm. It also provides another common parameter for specifying an IKE encryption algorithm and an ESP encryption algorithm. Therefore in the FortiGate appliance, you must specify the same hash algorithm and same encryption algorithm in IKE (phase 1 configuration) and ESP (phase 2 configuration).

- You must configure the firewall at the NetScaler end and FortiGate end to allow the following.
  - Any UDP packets for port 500
  - Any UDP packets for port 4500
  - Any ESP (IP protocol number 50) packets
- FortiGate appliance supports two types of VPN tunnels: Policy-based and Route-based. Only policy-based VPN tunnel is supported between a FortiGate appliance and a NetScaler appliance.

Configuring FortiGate Appliance for the CloudBridge Connector Tunnel

To configure a CloudBridge Connector tunnel on a FortiGate appliance, use the Fortinet Web-based Manager, which is the primary user interface for configuring, monitoring, and maintaining FortiGate appliances.

Before you begin the CloudBridge Connector tunnel configuration on a FortiGate appliance, make sure that:

- You have a user account with administrator credentials on the FortiGate appliance.
- You are familiar with the Fortinet Web-based Manager.
- The FortiGate appliance is UP and running, is connected to the Internet, and is also connected to the private subnets whose traffic is to be protected over the CloudBridge Connector tunnel.

Note: The procedures for configuring CloudBridge Connector tunnel on a FortiGate appliance might change over time, depending on the Fortinet release cycle. Citrix recommends that you follow the official Fortinet product documentation for Configuring IPSec VPN tunnels, at:

http://www.fortinet.com

To configure a CloudBridge connector tunnel between a NetScaler appliance and a FortiGate appliance, perform the following tasks on the FortiGate appliance by using the Fortinet Web-based manager:

- **Enable Policy-based IPSec VPN feature**. Enable this feature for creating policy-based VPN tunnels on the FortiGate appliance. Only policy-based type of VPN tunnel is supported between a FortiGate appliance and a NetScaler appliance. A policy-based VPN tunnel configuration on a FortiGate appliance includes phase 1 settings, phase 2 settings, and an IPSec security policy.
- **Define phase 1 parameters.** Phase 1 parameters are used by the FortiGate appliance for IKE Authentication before forming a secure tunnel to the NetScaler appliance.
- **Define phase 2 parameters**. Phase 2 parameters are used by the FortiGate appliance for forming a secure tunnel to the NetScaler appliance by establishing IKE security associations (SA).
- **Specify private subnets**. Define the FortiGate-side and the NetScaler-side private subnets whose IP traffic is to be transported through the tunnel.
- **Define an IPSec security policy for the tunnel**. A security policy allow IP traffic to pass between interfaces on a FortiGate appliance. An IPSec security policy specifies the interface to the private subnet and the interface connecting the NetScaler appliance through the tunnel.

To enable Policy-based IPSec VPN feature by using the Fortinet Web-based Manager

1. Navigate to **System** > **Config** > **Features**.
2. On the **Feature Settings** page, select **Show More** and turn on **Policy-based IPSec VPN**.

To define phase 1 parameters by using the Fortinet Web-based Manager

1. Navigate to **VPN** > **IPsec** > **Auto Key (IKE)** and click **Create Phase1**.
2. On the **New Phase 1** page, set the following parameters:

- Name: Enter a name for this phase 1 configuration.
- Remote Gateway: Select *Static IP Address.*
- Mode: Select *Main (ID Protection)*.
- Authentication Method: Select *Preshared Key*.
- Pre-Shared Key: Enter a pre-shared key. The same pre-shared key must be configured on the NetScaler appliance.
- Peer Options: Set the following IKE paramters for authenticating a NetScaler appliance.
  - IKE Version: Select *1*.
  - Mode Config: Clear this option if it is selected.
  - Local Gateway IP: Select *Main Interface IP*.
  - P1 Proposal: Select the encryption and authentication algorithms for IKE Authentication before forming a secure tunnel to the NetScaler appliance.
    - 1 - Encryption: Select *AES128*.
    - Authentication: Select *SHA1*.
    - Keylife: Enter an amount of time (in seconds) for the phase 1 key life.
    - DH Group: Select 2.
  - X-Auth: Select *Disable*.
  - Deed Peer Detection: Select this option.

3. Click **OK**.

To specify private subnets by using the Fortinet Web-based Manager

1. Navigate to **Firewall Objects** > **Address** > **Addresses** and select **Create New**.
2. On the **New Address** page, set the following parameters:
   - Name: Enter a name for FortiGate-side subnet.
   - Type: Select *Subnet*.
   - Subnet / IP Range: Enter the address of the FortiGate-side subnet.
   - Interface: Select the local interface to this subnet.
3. Click **OK**.
4. Repeat steps 1-3 to specify the NetScaler-side subnet.

To define phase 2 parameters by using the Fortinet Web-based Manager

1. Navigate to **VPN** > **IPsec** > **Auto Key (IKE)** and click **Create Phase 2**.
2. On the **New Phase 2** page, set the following parameters:
   - Name: Enter a name for this phase 2 configuration.
   - Phase 1: Select the Phase 1 configuration from the drop-down list.
3. Click **Advanced** and set the following parameters:
   - P2 Proposal: Select the encryption and authentication algorithms for forming a secure tunnel to the NetScaler appliance.
     - 1 - Encryption: Select *AES128*.
     - Authentication: Select *SHA1*.
     - Enable replay detection: Select this option.
     - Enable perfect forward secrecy (PFS): Select this option.
     - DH Group: Select *2*.
   - Keylife: Enter an amount of time (in seconds) for the phase 2 key life.
   - Autokey Keep Alive: Select this option.
   - Auto-negotiate: Select this option.
   - Quick Mode Selector: Specify the FortiGate-side and the NetScaler-side private subnets whose traffic is to be

traversed through the tunnel.
- Source Address: Select the FortiGate-side subnet from the drop-down list.
- Source Port: Enter *0*.
- Destination Address: Select the NetScaler-side subnet from the drop-down list.
- Destination Port: Enter *0*.
- Protocol: Enter *0*.

4. Click **OK**.

To define an IPSec security policy by using the Fortinet Web-based Manager

1. Navigate to **Policy** > **Policy** > **Policy** and click **Create New**.
2. On the **Edit Policy** page, set the following parameters:
   - Policy Type: Select *VPN*.
   - Policy Subtype: Select *IPSec*.
   - Local Interface: Select the local interface to the internal (private) network.
   - Local Protected Subnet: Select the FortiGate-side subnet from the drop-down list whose traffic is to be traversed through the tunnel.
   - Outgoing VPN Interface: Select the local interface to the external (public) network.
   - Remote Protected Subnet: Select the NetScaler-side subnet from the drop-down list whose traffic is to be traversed through the tunnel.
   - Schedule: Keep the default setting (*always*) unless changes are needed to meet specific requirements.
   - Service: Keep the default setting (*ANY*) unless changes are needed to meet your specific requirements.
   - VPN Tunnel: Select *Use Existing* and select the tunnel from the drop-down list.
   - Allow traffic to be initiated from the remote site: Select if traffic from the remote network will be allowed to initiate the tunnel.
3. Click **OK**.

Configuring the NetScaler Appliance for the CloudBridge Connector Tunnel

To configure a CloudBridge Connector tunnel between a NetScaler appliance and a FortiGate appliance, perform the following tasks on the NetScaler appliance. You can use either the NetScaler command line or the NetScaler graphical user interface (GUI):

- **Create an IPSec profile**. An IPSec profile entity specifies the IPSec protocol parameters, such as IKE version, encryption algorithm, hash algorithm, and authentication method to be used by the IPSec protocol in the CloudBridge Connector tunnel.
- **Create an IP tunnel that uses IPSec protocol, and associate the IPSec profile with it**. An IP tunnel specifies the local IP address (CloudBridge Connector tunnel end point IP address (of type SNIP) configured on the NetScaler appliance), remote IP address (CloudBridge Connector tunnel endpoint IP address configured on the FortiGate appliance), protocol (IPSec) used to set up the CloudBridge Connector tunnel, and an IPSec profile entity. The created IP tunnel entity is also called the CloudBridge Connector tunnel entity.
- **Create a PBR rule and associate it with the IP tunnel**. A PBR entity specifies a set of rules and an IP tunnel (CloudBridge Connector tunnel) entity. The source IP address range and the destination IP address range are the conditions for the PBR entity. Set the source IP address range to specify the NetScaler-side subnet whose traffic is to be protected over the tunnel, and set the destination IP address range to specify the FortiGate appliance side subnet whose traffic is to be protected over the tunnel.

To create an IPSEC profile by using the NetScaler command line

At the command prompt, type:

- **add ipsec profile** <name> -**psk** <string> -**ikeVersion v1** -**encAlgo AES** -**hashAlgo HMAC_SHA1** -**perfectForwardSecrecy ENABLE**
- **show ipsec profile** <name>

To create an IPSEC tunnel and bind the IPSEC profile to it by using the NetScaler command line

At the command prompt, type:

- **add ipTunnel** <name> <remote> <remoteSubnetMask> <local> -**protocol IPSEC** –**ipsecProfileName** <string>
- **show ipTunnel** <name>

To create a PBR rule and bind the IPSEC tunnel to it by using the NetScaler command line

At the command prompt, type:

- **add pbr** <pbrName> **ALLOW** –**srcIP** <subnet-range> -**destIP** <subnet-range> -**ipTunnel** <tunnelName>
- **apply pbrs**
- **show pbr** <pbrName>

To create an IPSEC profile by using the NetScaler GUI

1. Navigate to **System** > **CloudBridge Connector** > **IPSec Profile**.
2. In the details pane, click **Add**.
3. In the **Add IPSec Profile** page, set the following parameters:
   - Name
   - Encryption Algorithm
   - Hash Algorithm
   - IKE Protocol Version
   - Perfect Forward Secrecy (Enable this paramter)
4. Configure the IPSec authentication method to be used by the two CloudBridge Connector tunnel peers to mutually authenticate: Select the Pre-shared key authentication method and set the Pre-Shared Key Exists parameter.
5. Click **Create**, and then click **Close**.

To create an IP tunnel and bind the IPSEC profile to it by using the NetScaler GUI

1. Navigate to **System** > **CloudBridge Connector** > **IP Tunnels**.
2. On the **IPv4 Tunnels** tab, click **Add**.
3. In the **Add IP Tunnel** page, set the following parameters:
   - Name
   - Remote IP
   - Remote Mask
   - Local IP Type (In the Local IP Type drop-down list, select *Subnet IP*).
   - Local IP (All the configured IP addresses of the selected IP type are in the Local IP drop down list. Select the desired IP from the list.)
   - Protocol
   - IPSec Profile
4. Click **Create**, and then click **Close**.

To create a PBR rule and bind the IPSEC tunnel to it by using the NetScaler GUI

1. Navigate to **System** > **Network** > **PBR**.
2. On the **PBR** tab, click **Add**.
3. In the **Create PBR** page, set the following parameters:
   - Name
   - Action
   - Next Hop Type (Select *IP Tunnel*)
   - IP Tunnel Name
   - Source IP Low
   - Source IP High
   - Destination IP Low
   - Destination IP High
4. Click **Create**, and then click **Close**.

The corresponding new CloudBridge Connector tunnel configuration on the NetScaler appliance appears in the NetScaler GUI.

The current status of the CloudBridge connector tunnel is shown in the Configured CloudBridge Connector pane. A green dot indicates that the tunnel is up. A red dot indicates that the tunnel is down.

Sample Configuration COPY

```
The following commands create settings of NetScaler appliance NS_Appliance-1 in "Example of a CloudBridge Connector Configuration."

> add ipsec profile NS_Fortinet_IPSec_Profile -psk  examplepresharedkey -ikeVersion v1 –encAlgo AES –hashalgo HMAC_SHA1 –lifetim

 Done

> add iptunnel NS_Fortinet_Tunnel 203.0.113.200 255.255.255.255 198.51.100.100 –protocol IPSEC –ipsecProfileName NS_Fortinet_IP

 Done

> add pbr NS_Fortinet_Pbr -srcIP 10.102.147.0-10.102.147.255 –destIP 10.20.0.0-10.20.255.255 –ipTunnel NS_Fortinet_Tunnel

 Done

> apply pbrs

 Done
```

Monitoring the CloudBridge Connector Tunnel

You can monitor the performance of CloudBridge Connector tunnels on a NetScaler appliance by using CloudBridge Connector tunnel statistical counters. For more information about displaying CloudBridge Connector tunnel statistics on a

NetScaler appliance, see Monitoring CloudBridge Connector Tunnels.

CloudBridge Connector Tunnel Diagnostics and Troubleshooting

Jan 09, 2017

If you have problems with a CloudBridge Connector tunnel configuration, make sure that all prerequisites were observed before the tunnel was set up. If they were, the problem might be with the tunnel end-point IP addresses, a NAT configuration, the way the tunnel was set up, or with the data traffic.

Troubleshooting a CloudBridge Connector Tunnel

If your CloudBridge Connector tunnel does not function properly, the issue could be with tunnel establishment or with the data traffic. If you are unsure which type of problem you have, look for an error message in the log file and see if the error message is in the list of tunnel-establishment issues. If you do not find your error message, check the list of possible issues related to data traffic.

Issues Related to Tunnel Establishment

After the requirements for configuring the IPSec tunnel are met and the CloudBridge Connector tunnel is configured, if the status of the tunnel is not UP, look for debugging information in the iked.log file on one or both NetScaler appliances configured as the tunnel end points.

On either appliance, type the following command at the NetScaler shell prompt:

cat /tmp/iked.debug | tee /var/iked.log

The following table lists some common errors and their solutions.

Error Log Message	Possible Cause	Solution
Retransmission count exceeded the limit **Log message example** 2013-02-04 15:47:52 [PROTO_ERR]: ike v2.c:616:ikev2_ti meout(): 3:5.5.5.2[500] - 5. 5.5.1[500]:0x0:ret ransmission count exceeded the limit	The tunnel on the other end is not yet configured, or firewall routing issues are preventing the exchange of IKE related packets (UDP port 500/4500).	• If the tunnel on the other end point is not configured, configure it. • If the tunnel settings (IKE Version, Encryption/Hash Algorithm, PSK/certificates) on one end point do not match those on the other end point, no proposal is agreed upon between the end points. Specify the same settings on both end points. • After you configure a CloudBridge Connector tunnel between two end points, if the IP tunnel entity in an end point does not enter the UP state within a few minutes, remove the IP tunnel entity and add it again. One minute is usually sufficient for tunnel establishment if both ends are Citrix

		NetScaler appliances. • If none of the above measures correct the problem, configure, between the same end points, another CloudBridge that uses only the GRE protocol. Configure the firewalls on both ends to allow GRE (protocol number 47) packets. Verify that you are able to ping the network at one end of CloudBridge Connector tunnel from the other end.
Authentication failure **Log message example** 2013-02-04 16:05:16 [PROTO_ERR]: ike v2_auth.c:615:ike v2_verify(): 8:5.5.5.2[500] - 5. 5.5.1[500]:0x8104 290:authenticatio n failure	The IPSec authentication parameters (PSK or the public and private key) are set to incorrect values.	• Configure the authentication parameters correctly on both NetScaler appliances.
Failed to find a socket for retransmission or could not find configuration **Log message example** 2013-02-04 15:47:44 [INTERNAL_ERR]: i sakmp.c:1844:isak mp_retransmit(): failed to find a socket for retransmission 2013-01-10 21:21:46 [PROTO_ERR]: ike v1.c:950:isakmp_ ph1begin_r(): couldn't find configuration.	The tunnel IP address is not yet available for IKE purposes, or the tunnel does not exist.	• Remove the IP tunnel entities on both tunnel end points and add them again. • If another IP tunnel entity exists, with Local IP set to the same IP address but with IPSec profile set to NONE, remove these two tunnel entities and add them again. First add the one with a valid IPSec profile, and then add the one with IPSec profile NONE. • Verify that the IP address is available for IKE purposes, by typing the following commands at the CloudBridge shell prompt: • **ifconfig -a | grep** <LocalTunnelEndPoint-IP> **Example** root@ns# ifconfig -a | grep 5.5.5.2 inet 5.5.5.2 netmask 0xffffff00 broadcast 5.5.5.255 • **netstat | grepudp | grep** <LocalTunnelEndPoint-IP> **Example**

		root@ns# netstat | grepudp | grep 5.5.5.2 udp4 0 0 5.5.5.2.sae-urn *.* udp4 0 0 5.5.5.2.isakmp *.*
The source port and destination ports shown in the /tmp/iked.debug are other than port 500. That is: src= <srcip> [<srcPort != 500>] dst= <dst tip>[<dstPort != 500>]) **Log message example** 2013-02-04 16:08:59 [INFO]: i ke_pfkey.c:490:sa db_log_add(): SADB_UPDATE ul_proto=255 src=5.5.5.1[4500] dst=5.5.5.2[4500] satype=ESP samode=transport spi=0x055fdd6d au thtype=HMAC-SHA -256 enctype=AES-CBC lifetime soft time=25741 bytes=0 hard time=28800 bytes=0	At least one of the CloudBridge end points is deployed behind a NAT device	• See Points to Consider when Configuring a CloudBridge Connector tunnel with a NAT Device for proper IP configuration for configuring a CloudBridge Connector tunnel. • Make sure that UDP traffic is unblocked and the IPSec tunnel configuration is correct on both CloudBridge instances, as described in Prerequisites and Points to Consider when Configuring a CloudBridge Connector tunnel with a NAT Device.

Issues Related to Data Traffic

If the data in the CloudBridge Connector tunnel are not exchanged properly between the tunnel end points, do the following.

- For a CloudBridge Connector tunnel that uses GRE and IPSec protocols:
  - Make sure that L2 mode is enabled on both of the CloudBridge Connector tunnel end points. To enable L2 mode, type the following command at the NetScaler command line interface:

    enable mode L2

  - If one of the CloudBridge Connector tunnel end points is a CloudBridge virtual appliance (VPX) and is provisioned on a VMware ESXi hypervisor, make sure that Promiscuous mode is set to Accept for the vSwitch associated with the CloudBridge VPX appliance.
  - If a VLAN is extended through a CloudBridge Connector tunnel, verify one-to-one mapping on the extended VLAN entity on each of the tunnel end points
  - Make sure that the IP tunnel entity is bound to the correct netbridge entity in each of the tunnel end points.
  - Verify that the ARP entry for the peer CloudBridge Connector tunnel end point exists on the local tunnel end point, by typing the following command at the NetScaler command line interface:

    show arp

- If the output shows an incomplete ARP entry, bidirectional traffic is not flowing through the tunnel. If bidirectional traffic is flowing, the ARP entry shows the name of tunnel interface for the devices on the other side of the tunnel.
- Remove the IP tunnel entities from both tunnel end points and add them again with the same parameters, but with the IPSec profile set to NONE, so that the tunnel uses only the GRE protocol.

  After verifying the following in the IP tunnel (that uses GRE protocol), configure the tunnel with IPSec parameters by specifying a valid IPSec profile to the respective IP tunnel entities on each of the tunnel end points.

  Proper PING or TCP flow through the tunnel.
  Proper flow of data traffic through the tunnel.

  After the configured tunnel (that uses GRE and IPSec protocols) is in UP state, if the data traffic does not flow properly through the tunnel, and if a NAT device was deployed in front of any or both of the tunnel end points, analyze the ingress and egress packets on the NAT devices.

- If a NetScaler appliance is used as Router or Gateway.
  - Make sure that L3 mode is enabled on the NetScaler appliance. To enable L3 mode, run the following command in the CloudBridge command line.
  - enable mode L3
  - If subnets are bound to a netbridge entity, make sure that correct IP tunnel entity is also bound to the netbridge.
  - Run the following command in the NetScaler command line to see where the packets (Input and Output)are getting dropped:

    stat ipsec counters

  - Make sure that the correct routes are configured on both the tunnel end points.
  - If no NAT device is deployed in front of the NetScaler appliance, make sure that the firewalls are configured to allow any ESP (IP protocol number 50) packets and any UDP packets for port 4500.

If none of the above measures result in successful exchange of traffic between the tunnel end points, contact Citrix Technical Support.

Checklist before Contacting Citrix Technical Support

For a speedy resolution, make sure that you have the following items ready before contacting Citrix Technical Support.

- Details of the deployment and network topology.
- Log file collected by typing the following command at the NetScaler shell prompt.
  cat /tmp/iked.debug | tee /var/log/iked.log

- Tech support bundle captured by typing the following command at the NetScaler command line.
  show techsupport

- Packet traces captured on both CloudBridge Connector tunnel end points. To start a packet trace, type the following command at the NetScaler command line.
  start nstrace -size 0

  To stop packet trace, type the following command at the NetScaler command line.

stop nstrace

- Output of the following command typed at the NetScaler command prompt.
  show arp

High Availability

Mar 19, 2012

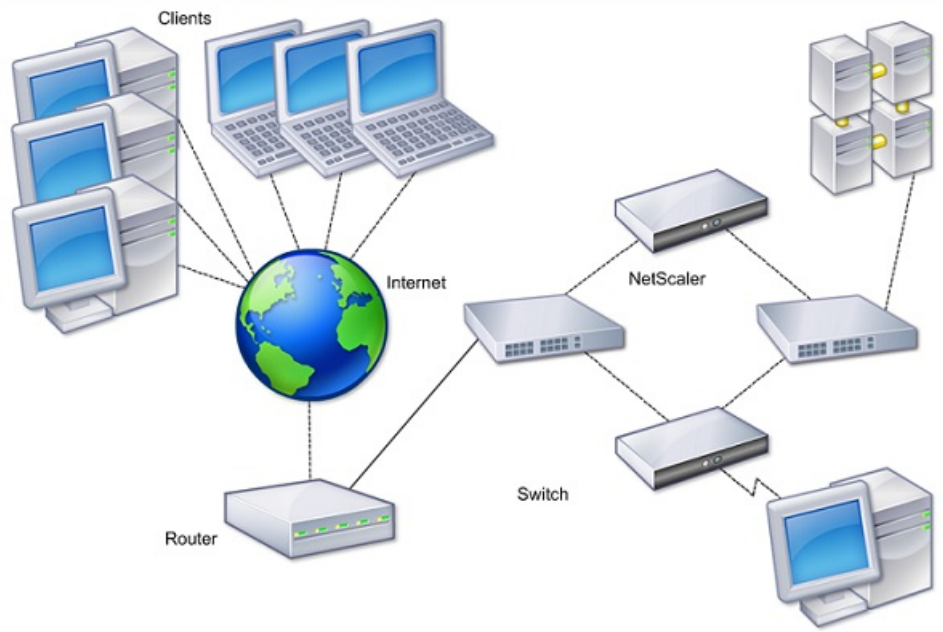
A high availability (HA) deployment of two Citrix® NetScaler® appliances can provide uninterrupted operation in any transaction. With one appliance configured as the primary node and the other as the secondary node, the primary node accepts connections and manages servers while the secondary node monitors the primary. If, for any reason, the primary node is unable to accept connections, the secondary node takes over.

The secondary node monitors the primary by sending periodic messages (often called heartbeat messages or health checks) to determine whether the primary node is accepting connections. If a health check fails, the secondary node retries the connection for a specified period, after which it determines that the primary node is not functioning normally. The secondary node then takes over for the primary (a process called failover).

After a failover, all clients must reestablish their connections to the managed servers, but the session persistence rules are maintained as they were before the failover.

With Web server logging persistence enabled, no log data is lost due to the failover. For logging persistence to be enabled, the log server configuration must carry entries for both systems in the log.conf file.

The following figure shows a network configuration with an HA pair.
Figure 1. NetScaler Appliances in a High Availability Configuration



To configure HA, you might want to begin by creating a basic setup, with both nodes in the same subnet. You can then customize the intervals at which the nodes communicate health-check information, the process by which nodes maintain synchronization, and the propagation of commands from the primary to the secondary. You can configure fail-safe mode to prevent a situation in which neither node is primary. If your environment includes devices that do not accept NetScaler gratuitous ARP messages, you should configure virtual MAC addresses. When you are ready for a more complex configuration, you can configure HA nodes in different subnets.

To improve the reliability of your HA setup, you can configure route monitors and create redundant links. In some situations, such as when troubleshooting or performing maintenance tasks, you might want to force a node to fail over (assign primary

status to the other node), or you might want to force the secondary node to stay secondary or the primary node to stay primary.

Points to Consider for a High Availability Setup

Mar 19, 2012

Note the following requirements for configuring systems in an HA setup:

- In an HA configuration, the primary and secondary NetScaler appliances should be of the same model. Different NetScaler models are not supported in an HA pair (for example, you cannot configure a 10010 model and a 7000 model as an HA pair).
- In an HA setup, both nodes must run the same version of NetScaler, for example, nCore/nCore or classic/classic. If the nodes are running NetScaler classic and you want to migrate to NetScaler nCore of the same NetScaler release, prop and sync are not supported during the migration process. Once migration is complete, prop and sync are auto-enabled. The same applies if you migrate from NetScaler nCore to NetScaler classic.
- Entries in the configuration file (ns.conf) on both the primary and the secondary system must match, with the following exceptions:
  - The primary and the secondary systems must each be configured with their own unique NetScaler IP addresses (NSIPs.)
  - In an HA pair, the node ID and associated IP address of one node must point to the other node. For example, if you have nodes NS1 and NS2, you must configure NS1 with a unique node ID and the IP address of NS2, and you must configure NS2 with a unique node ID and the IP address of NS1.
- If you create a configuration file on either node by using a method that does not go directly through the GUI or the CLI (for example, importing SSL certificates, or changing to startup scripts), you must copy the configuration file to the other node or create an identical file on that node.
- Initially, all NetScaler appliances are configured with the same RPC node password. RPC nodes are internal system entities used for system-to-system communication of configuration and session information. For security, you should change the default RPC node passwords.

  One RPC node exists on each NetScaler. This node stores the password, which is checked against the password provided by the contacting system. To communicate with other systems, each NetScaler requires knowledge of those systems, including how to authenticate on those systems. RPC nodes maintain this information, which includes the IP addresses of the other systems, and the passwords they require for authentication.

  RPC nodes are implicitly created when adding a node or adding a Global Server Load Balancing (GSLB) site. You cannot create or delete RPC nodes manually.

  Note: If the NetScaler appliances in a high availability setup are configured in one-arm mode, you must disable all system interfaces except the one connected to the switch or hub.
- For an IPv6 HA configuration, the following considerations apply:
  - You must install the IPv6PT license on both NetScaler appliances.
  - After installing the IPv6PT license, enable the IPv6 feature by using the configuration utility or the command line interface.
  - Both NetScaler appliances require a global NSIP IPv6 address. In addition, network entities (for example, switches and routers) between the two nodes must support IPv6.

Configuring High Availability

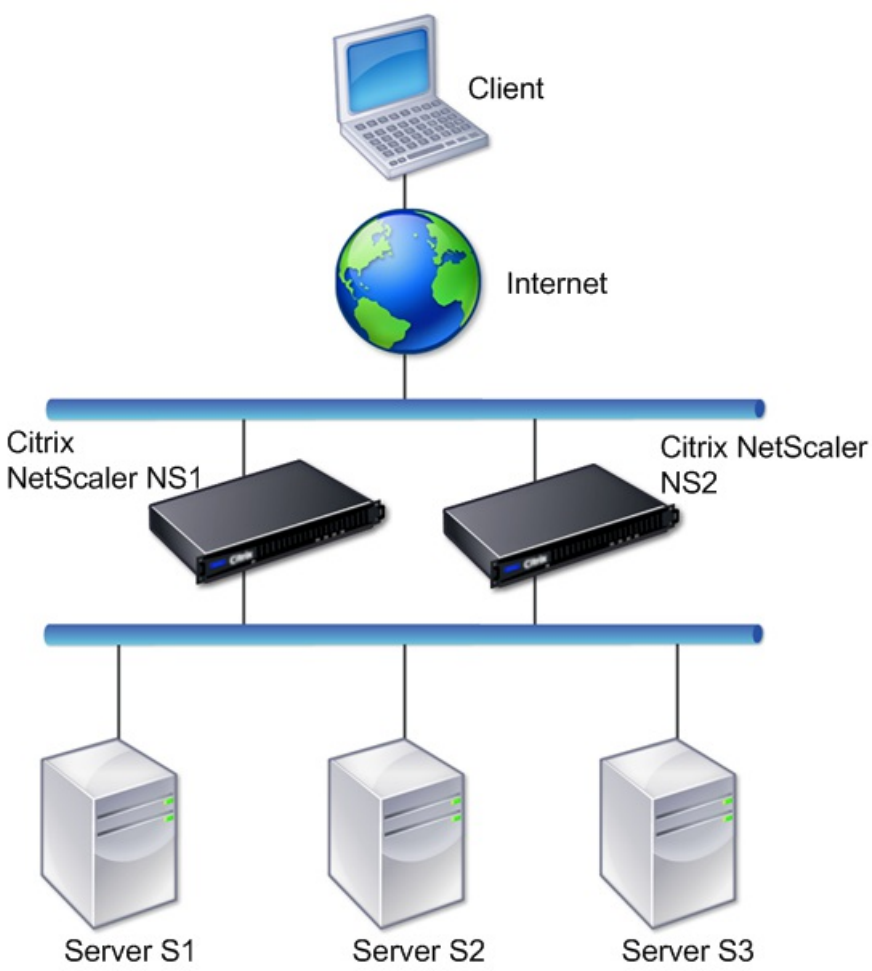
Sep 07, 2016

To set up a high availability configuration, you create two nodes, each of which defines the other's NetScaler IP (NSIP) address as a remote node. Begin by logging on to one of the two NetScaler appliances that you want to configure for high availability, and add a node. Specify the other appliance's NetScaler IP (NSIP) address as the address of the new node. Then, log on to the other appliance and add a node that has the NSIP address of the first appliance. An algorithm determines which node becomes primary and which becomes secondary.

Note: The configuration utility provides an option that avoids having to log on to the second appliance.

The following figure shows a simple HA setup, in which both nodes are in same subnet.

Figure 1. Two NetScaler Appliances Connected in a High Availability Configuration



Adding a Remote Node

To add a remote NetScaler appliance as a node in a high availability setup, you specify a unique node ID and the appliance's NSIP. The maximum number of node IDs in an HA setup is 64. When you add an HA node, you must disable the HA monitor for each interface that is not connected or not being used for traffic. For CLI users, this is a separate procedure.

Note: To ensure that each node in the high availability configuration has the same settings, you should synchronize your SSL certificates, startup scripts, and other configuration files with those on the primary node.

To add a node by using the command line interface

At the command prompt, type:

- add ha node <id> <IPAddress>
- show ha node

Example

> add ha node 10 203.0.113.32

To disable an HA monitor by using the command line interface

At the command prompt, type:

- set interface <ifNum> [-haMonitor (**ON** | **OFF**)]
- show interface <ifNum>

Example

> set interface 1/3 -haMonitor OFF
Done

To add a remote node by using the configuration utility

Navigate to **System** > **High Availability** and, on the **Nodes** tab, add a new remote node, or edit an existing node.

Disabling or Enabling a Node

Updated: 2013-08-28

You can disable or enable only a secondary node. When you disable a secondary node, it stops sending heartbeat messages to the primary node, and therefore the primary node can no longer check the status of the secondary. When you enable a node, the node takes part in the high availability configuration.

To disable or enable a node by using the command line interface

At the command prompt, type one of the following commands:

- set ha node -hastatus DISABLED
- set ha node -hastatus ENABLED

To disable or enable a node by using the configuration utility

1. Navigate to System > High Availability and, on the Nodes tab, open the node.
2. In the High Availability Status list, select ENABLED (Actively Participate in HA) or DISABLED (Do not participate in HA).

Removing a Node

Updated: 2013-08-28

If you remove a node, the nodes are no longer in high availability configuration.

To remove a node by using the command line interface

At the command prompt, type:

rm ha node <id>
Example

> rm ha node 10
Done

To remove a node by using the configuration utility

Navigate to System > High Availability and, on the Nodes tab, delete the node.

Configuring the Communication Intervals

Oct 28, 2016

The hello interval is the interval at which the heartbeat messages are sent to the peer node. The dead interval is the time interval after which the peer node is marked DOWN if heartbeat packets are not received. The heartbeat messages are UDP packets sent to port 3003 of the other node in an HA pair. Dead interval must be set as a multiple of hello interval.

To set the hello and dead intervals by using the command line interface

At the command prompt, type:

- set HA node [-helloInterval <msecs>] [-deadInterval <secs>]
- show HA node <id>

To set the hello and dead intervals by using the configuration utility

1. Navigate to System > High Availability and, on the Nodes tab, open the node.
2. Set the following parameters:
   - Hello Interval (msecs)
   - Dead Interval (secs)

Configuring Synchronization

Mar 19, 2012

Synchronization is a process of duplicating the configuration of the primary node on the secondary node. The purpose of synchronization is to ensure that there is no loss of configuration information between the primary and the secondary nodes, regardless of the number of failovers that occur. Synchronization uses port 3010.

Synchronization is triggered by either of the following circumstances:

- The secondary node in an HA setup comes up after a restart.
- The primary node becomes secondary after a failover.

Automatic synchronization is enabled by default. You can also force synchronization.

Disabling or Enabling Synchronization

Updated: 2013-08-28

Automatic HA synchronization is enabled by default on each node in an HA pair. You can enable or disable it on either node.

To disable or enable automatic synchronization by using the command line interface

At the command prompt, type:

- set HA node -haSync DISABLED
- set HA node -haSync ENABLED

To disable or enable synchronization by using the configuration utility

1. Navigate to System > High Availability and, on the Nodes tab, open the node.
2. Under HA Synchronization, clear or select the Secondary node will fetch the configuration from Primary option.

Forcing the Secondary Node to Synchronize with the Primary Node

Updated: 2013-08-28

In addition to automatic synchronization, the NetScaler supports forced synchronization. You can force the synchronization from either the primary or the secondary node. When you force synchronization from the secondary node, it starts synchronizing its configuration with the primary node.

However, if synchronization is already in progress, forced synchronization fails and the system displays a warning. Forced synchronization also fails in any of the following circumstances:

- You force synchronization on a standalone system.
- The secondary node is disabled.
- HA synchronization is disabled on the secondary node.

To force synchronization by using the command line interface

At the command prompt, type:

force HA sync

To force synchronization by using the configuration utility

1. Navigate to System > High Availability.
2. On the Nodes tab, in the Action list, click Force Synchronization.

Synchronizing Configuration Files in a High Availability Setup

Apr 15, 2016

In a high availability setup, all configuration files are synchronised automatically from the primary node to the secondary node at an interval of one minute. Synchronizing configuration files can be performed manually by using the command line interface or the configuration utility at either the primary or the secondary node.

Files located on the secondary that are specific to the secondary (not present on the primary) are not deleted during the synchronization.

At the command prompt, type:

sync HA files <mode>

Example

```
> sync HA files all
 Done
> sync HA files ssl
 Done
```

Parameter Descriptions (of the command listed in the CLI procedure)

sync ha files <mode>

mode

Specify one of the following modes of synchronization.

- **all** - Synchronize files related to system configuration, Access Gateway bookmarks, SSL certificates, SSL CRL lists, HTML injection scripts, and Application Firewall XML objects.
- **bookmarks** - Synchronize all Access Gateway bookmarks.
- **ssl** - Synchronize all certificates, keys, and CRLs for the SSL feature.
- **htmlinjection** - Synchronize all scripts configured for the HTML injection feature.
- **imports** - Synchronizeall XML objects (for example, WSDLs, schemas, error pages) configured for the application firewall.
- **misc** - Synchronize all license files and the rc.conf file.
- **all_plus_misc** - Synchronize files related to system configuration, Access Gateway bookmarks, SSL certificates, SSL CRL lists, HTML injection scripts, application firewall XML objects, licenses, and the rc.conf file.

Navigate to System > Diagnostics and, in the Utilities group, click Start HA files synchronization.

Configuring Command Propagation

Aug 28, 2013

In an HA setup, any command issued on the primary node propagates automatically to, and is executed on, the secondary before it is executed on the primary. If command propagation fails, or if command execution fails on the secondary, the primary node executes the command and logs an error. Command propagation uses port 3010.

In an HA pair configuration, command propagation is enabled by default on both the primary and secondary nodes. You can enable or disable command propagation on either node in an HA pair. If you disable command propagation on the primary node, commands are not propagated to the secondary node. If you disable command propagation on the secondary node, commands propagated from the primary are not executed on the secondary node.

Note: After reenabling propagation, remember to force synchronization.
If synchronization occurs while you are disabling propagation, any configuration-related changes that you make before the disabling of propagation takes effect are synchronized with the secondary node. This is also true for cases where propagation is disabled while synchronization is in progress.

At the command prompt, type:

- set HA node -haProp DISABLED
- set HA node -haProp ENABLED

1. Navigate to System > High Availability and, on the Nodes tab, open the node.
2. Clear or select the Primary node will propagate configuration to the Secondary option.

Restricting High-Availability Synchronization Traffic to a VLAN

Dec 18, 2015

In a high availability (HA) deployment, traffic related to maintaining the HA configurationflows between the two HA nodes. This traffic is of the following types:

- Config synchronization
- Config propagation
- Connection mirroring
- Load balancing persistency config synchronization
- Persistent session synchronization
- Session state synchronization

Proper flow of this HA related traffic between the two nodes is critical for the functioning of the HA deployment. Typically, the HA related traffic is small in volume but can become very high during a failover. It becomes very high if stateful connection failover is enabled and the node that was primary before the failover was handling a large number of connections.

By default, the HA related traffic flows through the VLANs to which the NSIP address is bound. To accommodate a potential surge in this traffic, you can separate the HA related traffic from the management traffic and restrict its flow to a separate VLAN. This VLAN is called the HA SYNC VLAN.

Points to Consider before Configuring an HA SYNC VLAN

- The configuration of an HA SYNC VLAN is neither propagated nor synchronized. In other words, the HA SYNC VLAN is node specific and is configured independently on each nodes.
- HA SYNC VLAN configuration is removed when you clear the configuration in only FULL mode.
- HA MON must be set to OFF for interfaces that are part of the HA SYNC VLAN, to avoid a situation in which both nodes function as the primary node.
- Management interfaces (for example, 0/1 and 0/2) must not be part of the HA SYNC VLAN, so that HA related traffic does not flow through management interfaces.

To configure an HA SYNC VLAN on a NetScaler node, specify a configured VLAN with the HA SYNC VLAN parameter of the local node entity.

To configure an HA SYNC VLAN on a local node by using the command line

At the command prompt, type:

- **set node –hasyncvlan** <VLANID>
- **show node**

Parameter Description

Hasyncvlan (Sync VLAN)

VLAN on which HA related traffic is sent. This includes traffic for synchronization, propagation, connection mirroring, load balancing persistency, configuration synchonization, persistent session synchr

To configure an HA SYNC VLAN on a node by using the configuration utility

1. Navigate to **System** > **High Availability**.
2. Set the **Sync VLAN** parameter while modifying the local node.

Configuring Fail-Safe Mode

Aug 28, 2013

In an HA configuration, fail-safe mode ensures that one node is always primary when both nodes fail the health check. This is to ensure that when a node is only partially available, backup methods are enabled to handle traffic as best as possible. The HA fail-safe mode is configured independently on each node.

The following table shows some of the fail-safe cases. The NOT_UP state means that the node failed the health check yet it is partially available. The UP state means that the node passed the health check.

Table 1. Fail-Safe Mode Cases

Node A (Primary) Health State	Node B (Secondary) Health State	Default HA Behavior	Fail-Safe Enabled HA Behavior	Description
NOT_UP(failed last)	NOT_UP (failed first)	A (Secondary), B (Secondary)	A (Primary), B (Secondary)	If both nodes fail, one after the other, the node that was the last primary remains primary.
NOT_UP (failed first)	NOT_UP(failed last)	A (Secondary), B (Secondary)	A(Secondary), B(Primary)	If both nodes fail, one after the other, the node that was the last primary remains primary.
UP	UP	A (Primary), B (Secondary)	A (Primary), B (Secondary)	If both nodes pass the health check, no change in behavior with fail-safe enabled.
UP	NOT_UP	A(Primary), B(Secondary)	A (Primary), B (Secondary)	If only the secondary node fails, no change in behavior with fail-safe enabled.
NOT_UP	UP	A(Secondary), B(Primary)	A(Secondary), B(Primary)	If only the primary fails, no change in behavior with fail-safe enabled.
NOT_UP	UP (STAYSECONDARY)	A (Secondary), B (Secondary)	A (Primary), B (Secondary)	If the secondary is configured as STAYSECONDARY, the primary remains primary even if it fails.

At the command prompt, type:

set HA node [-failSafe (**ON** | **OFF**)]

Example

```
set ha node -failsafe ON
```

1. Navigate to System > High Availability and, on the Nodes tab, open the node.
2. Under Fail-Safe Mode, select the Maintain one Primary node even when both nodes are unhealthy option.

Configuring Virtual MAC Addresses

Feb 13, 2017

A Virtual MAC address (VMAC) is a floating entity shared by the primary and the secondary nodes in an HA setup.

In an HA setup, the primary node owns all of the floating IP addresses, such as the MIPs, SNIPs, and VIPs. The primary node responds to Address Resolution Protocol (ARP) requests for these IP addresses with its own MAC address. As a result, the ARP table of an external device (for example, an upstream router) is updated with the floating IP address and the primary node's MAC address.

When a failover occurs, the secondary node takes over as the new primary node. It then uses Gratuitous ARP (GARP) to advertise the floating IP addresses that it acquired from the primary. However, the MAC address that the new primary advertises is the MAC address of its own interface.

Some devices (notably a few routers) do not accept the GARP messages generated by the NetScaler appliance. As a result, some external devices retain the old IP to MAC mapping advertised by the old primary node. This can result in a site going down.

You can overcome this problem by configuring a VMAC on both nodes of an HA pair. Both nodes then possess identical MAC addresses. Therefore, when failover occurs, the MAC address of the secondary node remains unchanged, and the ARP tables on the external devices do not need to be updated.

To create a VMAC, you need to first create a Virtual Router ID (VRID) and bind it to an interface. (In an HA setup, you need to bind the VRID to the interfaces on both nodes.) Once the VRID is bound to an interface, the system generates a VMAC with the VRID as the last octet.

This section includes the following details:

- Configuring IPv4 VMACs
- Configuring IPv6 VMAC6s

When you create a IPv4 VMAC address and bind it to a interface, any IPv4 packet sent from the interface uses the VMAC address that is bound to the interface. If there is no IPv4 VMAC bound to an interface, the interface's physical MAC address is used.

The generic VMAC is of the form 00:00:5e:00:01:<VRID>. For example, if you create a VRID with a value of 60 and bind it to an interface, the resulting VMAC is 00:00:5e:00:01:3c, where 3c is the hex representation of the VRID. You can create 255 VRIDs with values from 1 to 255.

Creating or Modifying an IPv4 VMAC

Updated: 2013-08-28

You create an IPv4 virtual MAC by assigning it a virtual router ID. You can then you bind the VMAC to an interface. You cannot bind multiple VRIDs to the same interface. To verify the VMAC configuration, you should display and examine the VMACs and the interfaces bound to the VMACs.

At the command prompt, type:

- add vrID <id>
- bind vrid <id> -ifnum <interface_name>
- show vrID

Example

```
> add vrID 100
 Done
> bind vrid 100 -ifnum 1/1 1/2 1/3
 Done
```

At the command prompt, type:

- unbind vrid <id> -ifnum <interface_name>
- show vrID

Navigate to System > Network > VMAC and, on the VMAC tab, add a new VMAC, or edit an existing VMAC.

Removing an IPv4 VMAC

Updated: 2013-08-28

To remove an IPv4 virtual MAC, you delete its virtual router ID.

At the command prompt, type:
rm vrid <id>

Example

```
rm vrid 100s
```

Navigate to System > Network > VMAC and, on the VMAC tab, delete the IPv4 VMAC.

The NetScaler supports VMAC6 for IPv6 packets. You can bind any interface to a VMAC6, even if an IPv4 VMAC is bound to the interface. Any IPv6 packet sent from the interface uses the VMAC6 bound to that interface. If there is no VMAC6 bound to an interface, an IPv6 packet uses the physical MAC.

Creating or Modifying a VMAC6

Updated: 2013-08-28

You create an IPv6 virtual MAC by assigning it an IPv6 virtual router ID. You can then you bind the VMAC to an interface. You cannot bind multiple IPv6 VRIDs to an interface. To verify the VMAC6 configuration, you should display and examine the VMAC6s and the interfaces bound to the VMAC6s.

At the command prompt, type:

- add vrID6 <id>
- bind vrID6 <id> -ifnum <interface_name>
- show vrID6

Example

```
> add vrID6 100
Done
> bind vrID6 100 -ifnum 1/1 1/2 1/3
 Done
```

At the command prompt, type:

- unbind vrID6 <id> -ifnum <interface_name>
- show vrID6

Navigate to System > Network > VMAC and, on the VMAC6 tab, add a new VMAC6, or edit an existing VMAC6.

Removing a VMAC6

Updated: 2013-08-28

To remove an IPv4 virtual MAC, you delete its virtual router ID.

At the command prompt, type:
rm vrid6 <id>

Example

```
rm vrid6 100s
```

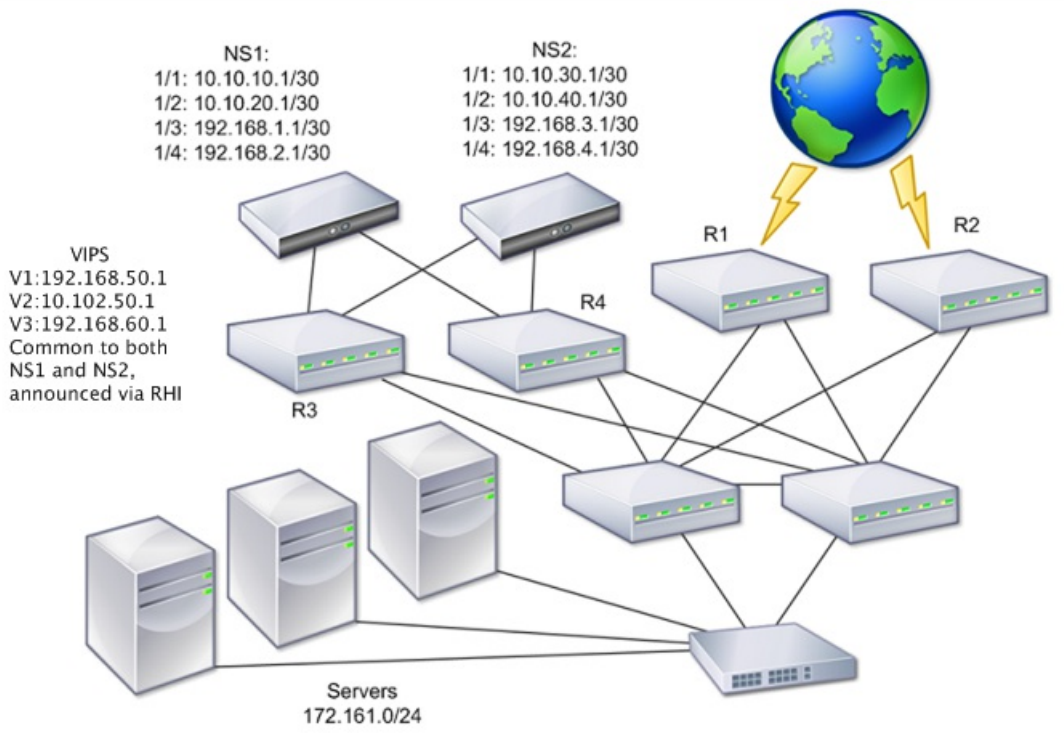
Navigate to System > Network > VMAC and, on the VMAC6 tab, delete the virtual router ID.

Configuring High Availability Nodes in Different Subnets

Sep 07, 2016

The following figure shows an HA deployment with the two systems located in different subnets:

Figure 1. High Availability over a Routed Network



In the figure, the systems NS1 and NS2 are connected to two separate routers, R3 and R4, on two different subnets. The NetScaler appliances exchange heartbeat packets through the routers. This configuration could be expanded to accommodate deployments involving any number of interfaces.

Note: If you use static routing on your network, you must add static routes between all the systems to ensure that heartbeat packets are sent and received successfully. (If you use dynamic routing on your systems, static routes are unnecessary.)

If the nodes in an HA pair reside on two separate networks, the primary and secondary node must have independent network configurations. This means that nodes on different networks cannot share entities such as SNIPs, VLANs, and routes. This type of configuration, where the nodes in an HA pair have different configurable parameters, is known as Independent Network Configuration (INC) or Symmetric Network Configuration (SNC).

The following table summarizes the configurable entities and options for an INC, and shows how they must be set on each node.

Table 1. Behavior of NetScaler Entities and Options in an Independent Network Configuration

NetScaler entities	Options

NetScaler entities	Options
IPs (NSIP/SNIPs)	Node-specific. Active only on that node.
VIPs	Floating.
VLANs	Node-specific. Active only on that node.
Routes	Node-specific. Active only on that node. Link load balancing routes are floating.
ACLs	Floating (Common). Active on both nodes.
Dynamic routing	Node-specific. Active only on that node. The secondary node should also run the routing protocols and peer with upstream routers.
L2 mode	Floating (Common). Active on both nodes.
L3 mode	Floating (Common). Active on both nodes.
Reverse NAT (RNAT)	Node-specific. RNAT with VIP, because NATIP is floating.

As in configuring HA nodes in the same subnet, to configure HA nodes in different subnets, you log on to each of the two NetScaler appliances and add a remote node representing the other appliance.

When two nodes of an HA pair reside on different subnets, each node must have a different network configuration. Therefore, to configure two independent systems to function as an HA pair, you must specify INC mode during the configuration process.

When you add an HA node, you must disable the HA monitor for each interface that is not connected or not being used for traffic. For CLI users, this is a separate procedure.

To add a node by using the command line interface

At the command prompt, type:

- add ha node <id> <IPAddress> -inc ENABLED
- show ha node

Example

```
> add ha node 3 10.102.29.170 -inc ENABLED
 Done
> add ha node 3 1000:0000:0000:0000:0005:0600:700a:888b
```

Done

To disable an HA monitor by using the command line interface

At the command prompt, type:

- set interface <ifNum> [-haMonitor (**ON** | **OFF**)]
- show interface <ifNum>

Example

```
> set interface 1/3 -haMonitor OFF
 Done
```

To add a remote node by using the configuration utility

1. Navigate to System > High Availability and, on the Nodes tab, add a new remote node.
2. Make sure to select the Turn off HA monitor on interfaces/channels that are down and Turn on INC (Independent Network Configuration) mode on self mode options.

Updated: 2013-08-28

If you remove a node, the nodes are no longer in high availability configuration.

To remove a node by using the command line interface

At the command prompt, type:

rm ha node <id>

Example

```
> rm ha node 2
 Done
```

To remove a node by using the configuration utility

Navigate to System > High Availability and, on the Nodes tab, delete the node.

Note: You can use the Network Visualizer to view the NetScaler appliances that are configured as a high availability (HA) pair and perform high availability configuration tasks.

Configuring Route Monitors

Sep 06, 2013

You can use route monitors to make the HA state dependent on the internal routing table, whether or not the table contains any dynamically learned or static routes. In an HA configuration, a route monitor on each node watches the internal routing table to make sure that a route entry for reaching a particular network is always present. If the route entry is not present, the state of the route monitor changes to DOWN.

When a NetScaler appliance has only static routes for reaching a network, and you want to create a route monitor for the network, you must enable monitored static routes (MSR) for the static routes. MSR removes unreachable static routes from the internal routing table. If MSR is disabled on static routes, an unreachable static route can remain in the internal routing table, defeating the purpose of having the route monitor.

Route Monitors are supported both in non-INC and INC mode.

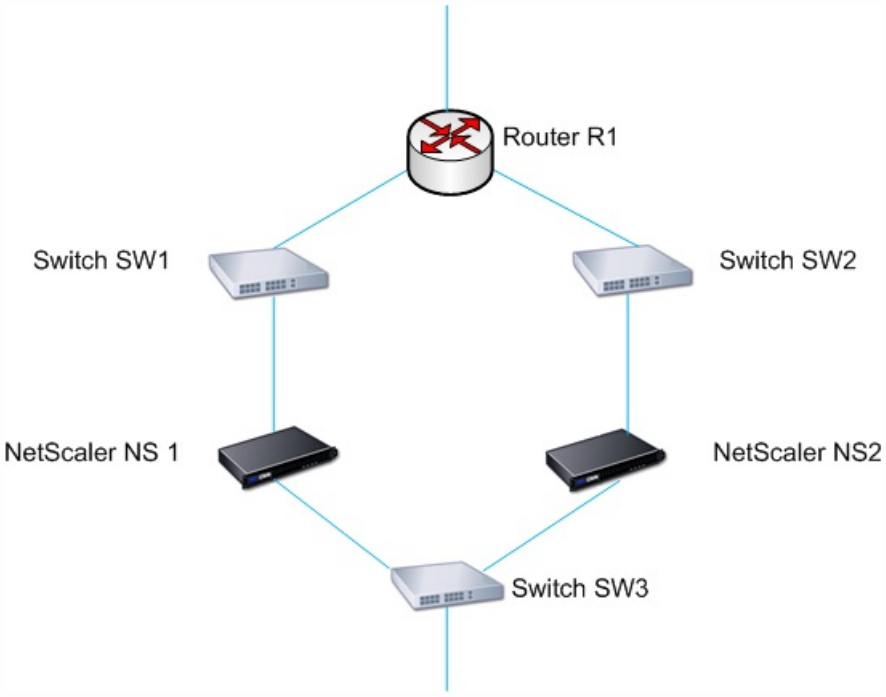
Route Monitors in HA in non-INC mode	Route Monitors in HA in INC mode
Route monitors are propagated by nodes and exchanged during synchronization.	Route monitors are neither propagated by nodes nor exchanged during synchronization.
Route monitors are active only in the current primary node.	Route monitors are active on both the primary and the secondary node.
The NetScaler appliance always displays the state of a route monitor as UP irrespective of the whether the route entry is present or not in the internal routing table.	The NetScaler appliance displays the state of the route monitor as DOWN if the corresponding route entry is not present in the internal routing table.
A route monitor starts monitoring its route after 180 seconds in the following cases [This is done to allow dynamic routes to get learnt, which may take 180 secs]: • reboot • failover • set route6 command for v6 routes • set route msr enable/disable command for v4 routes. • adding a new route monitor	-

Route monitors are useful in a non-INC mode HA configuration where you want the non-reachability of a gateway from a primary node to be one of the conditions for HA failover.

Consider an example of a non-Inc mode HA setup in a two-arm topology that has NetScaler appliances NS1 and NS2 in the same subnet, with router R1 and switches SW1, SW2, and SW3.

Because R1 is the only router in this setup, you want the HA setup to failover whenever R1 is not reachable from the current primary node. You can configure a route monitor (say, RM1 and RM2, respectively) on each of the nodes to monitor the reachability of R1 from that node.

Figure 1.



With NS1 as the current primary node, the execution flow is as follows:

1. Route monitor RM1 on NS1 monitors NS1's internal routing table for the presence of a route entry for router R1. NS1 and NS2 exchange heartbeat messages through switch SW1 or SW3 at regular intervals.
2. If switch SW1 goes down, the routing protocol on NS1 detects that R1 is not reachable and therefore removes the route entry for R1 from the internal routing table. NS1 and NS2 exchanges heartbeat messages through switch SW3 at regular intervals.
3. Detecting that the route entry for R1 is not present in the internal routing table, RM1 initiates a failover. If route to R1 is down from both NS1 and NS2, failover happens every 180 seconds till one of the appliances is able to reach R1 and restore the connectivity.

A single procedure creates a route monitor and binds it to an HA node.

To add a route monitor by using the command line interface

At the command prompt, type:

- bind HA node <id> (-routeMonitor <ip_addr|ipv6_addr> [<netmask>])
- show HA node

Example

```
> bind HA node 0 -routeMonitor 10.102.71.0 255.255.255.0
 Done
> bind HA node 0 -routeMonitor 1000:0000:0000:0000:0005:0600:700a:888b
 Done
```

To add a route monitor by using the configuration utility

Navigate to System > High Availability and, on the Route Monitors tab, click Configure.

Updated: 2013-08-28

To remove a route monitor by using the command line interface

At the command prompt, type:

- unbind HA node <id> (-routeMonitor <ip_addr|ipv6_addr> [<netmask>])
- show ha node

Example

```
unbind HA node 3 -routeMonitor 10.102.71.0 255.255.255.0
unbind HA node 3 -routeMonitor 1000:0000:0000:0000:0005:0600:700a:888b
```

To remove a route monitor by using the configuration utility

Navigate to System > High Availability and, on the Route Monitors tab, delete the route monitor.

Limiting Failovers Caused by Route Monitors in non-INC mode

Jul 05, 2016

In an HA configuration in non-INC mode, if route monitors fail on both nodes, failover happens every 180 seconds until one of the nodes is able to reach all of the routes monitored by the respective route monitors.

However, for a node, you can limit the number of failovers for a given interval by setting the Maximum Number of Flips and Maximum Flip Time parameters on the nodes. When either limit is reached, no more failovers occur, and the node is assigned as primary (but node state as NOT UP) even if any route monitor fails on that node. This combination of HA state as Primary and Node state as NOT UP is called Stick Primary state.

If the node is then able to reach all of the monitored routes, the next monitor failure triggers resetting of the Maximum Number of Flips and Maximum Flip Time parameters on the node and starting the time specified in the Maximum Flip Time parameter.

These parameters are set independently on each node and therefore are neither propagated nor synchronized.

Parameters for limiting the number of failovers

Maximum Number of Flips (maxFlips)

Maximum number of failovers allowed, within the Maximum Flip Time interval, for the node in HA in non INC mode, if the failovers are caused by route-monitor failure.

Maximum Flip Time (maxFlipTime)

Amount of time, in seconds, during which failovers resulting from route-monitor failure are allowed for the node in HA in non INC mode.

To limit the number of failovers by using the command line interface

At the command prompt, type:

- **set HA node** [-**maxFlips** < positive_integer>] [-**maxFlipTime** <positive_integer>]
- **show HA node** [< id>]

To limit the number of failovers by using the configuration utility

1. Navigate to **System** > **High Availability** and, on the **Nodes** tab, open the local node.
2. Set the following parameters:

- Maximum Number of Flips
- Maximum Flip Time

```
> set ha node -maxFlips 30 -maxFlipTime 60
```

```
Done

> sh ha node

1) Node ID: 0

SNMP Alarm for Sticky Primary State

Enable HA-STICKY-PRIMARY SNMP alarm in a node of a high availability set up if you want to be alerted of the node becoming sticky primary. When the node becomes sticky primary, it alerts by generating a trap message (stickyPrimary (1.3.6.1.4.1.5951.1.1.0.138)) and sends it to all the configured SNMP trap destinations. For more information about configuring SNMP alarms and trap destinations, see Configuring the NetScaler to Generate SNMPv1 and SNMPv2 Traps.

Frequently Asked Questions

Consider an example of a high availability setup of two NetScaler appliances NS-1 and NS-2 in non-INC mode. Maximum numbers of flips and maximum flip time in both the nodes have been set with the same values.

The following table lists the settings used in this example:

Entity	Detail
IP address of NS-1	10.102.173.211
IP address of NS-2	10.102.173.212
Maximum number of flips	2
Maximum flip time	200

The following table lists some FAQs and answers about maximum number of flips and maximum flip time settings:

Question	Answer
What must be the next plan of action after one of the node become sticky primary?	Rectify the routes, which are being monitored. After the maximum flip time is elapsed, any route monitor failure triggers resetting of the Maximum number of flips and maximum flip time, then starting the time specified in maximum flip time. The following example shows that NS-1 (10.102.173.211) becomes

	sticky primary. > show ha node 1) Node ID: 0 IP: 10.102.173.211 Node State: NOT UP Master State: Primary . . 2) Node ID: 1 IP: 10.102.173.212 Node State: UP Master State: Secondary . . Local node information: Route Monitor - Network: 10.102.173.216 Netmask: 255.255.255.255 State: DOWN Critical Interfaces: 1/1 1/2 **Configured/Completed Flips: 2/2** **Configured/Remaining Flip Time: 200/0** Done
What happens if a node recovers from sticky primary state before the maximum flip time is elapsed?	Nothing happens. Maximum number of flips and maximum flip time are not reset.
What happens if a node recovers from sticky primary state after the maximum flip time is elapsed?	Nothing happens. Maximum number of flips and maximum flip time are not reset.
What happens if a node recovers from sticky primary state and then the route that is being monitored goes down again before the maximum flip time is elapsed?	The node will again become sticky primary without a failover. Maximum number of flips and maximum flip time are not reset.

The following example shows that NS-1 (10.102.173.211) recovers from sticky primary state. NS-1 again becomes sticky primary when the route that is being monitored goes down again before the maximum flip time is elapsed.

> show ha node

1) Node ID: 0

IP: 10.102.173.211

Node State: UP

Master State: Primary

.

.

2) Node ID: 1

IP: 10.102.173.212

Node State: UP

Master State: Secondary

.

.

Local node information:

Configured/Completed Flips: 2/2
Configured/Remaining Flip Time: 200/113

Done

> show ha node

1) Node ID: 0

IP: 10.102.173.211

Node State: NOT UP

Master State: Primary

.

.

	2) Node ID: 1 IP: 10.102.173.212 Node State: UP Master State: Secondary . . Local node information: Route Monitor - Network: 10.102.173.216 Netmask: 255.255.255.255 State: DOWN Critical Interfaces: 1/1 1/2 **Configured/Completed Flips: 2/2** **Configured/Remaining Flip Time: 200/83** Done
What happens if a node recovers from sticky primary state and then the route that is being monitored goes down again after the maximum flip time is elapsed?	Maximum number of flips and maximum flip time are reset to the configured values. Then, Maximum flip time starts. Also, failover happens until either of the following condition is achieved: • one of the nodes is able to reach all of the routes monitored by the respective route monitors. • number of failover equals the maximum number of flips The following example shows that NS-1 (10.102.173.211) recovers from sticky primary state. When the route (10.102.173.216) that is being monitored goes down again before the maximum flip time is elapsed, maximum number of flips and maximum flip time are reset, and maximum flip time starts. The second output of show ha node shows NS-1 becomes secondary after a failover. > show ha node 1) Node ID: 0 IP: 10.102.173.211 Node State: UP

Master State: Primary

.

.

2) Node ID: 1

Configured/Completed Flips: 2/2

Configured/Remaining Flip Time: 200/0

Done

> show ha node

1) Node ID: 0

IP: 10.102.173.211

Node State: UP

Master State: Primary

.

.

2) Node ID: 1

IP: 10.102.173.212

Node State: UP

Master State: Secondary

.

.

	Local node information: Route Monitor - Network: 10.102.173.216 Netmask: 255.255.255.255 State: UP Critical Interfaces: 1/1 1/2 **Configured/Completed Flips: 2/1** **Configured/Remaining Flip Time: 200/196** Done
What happens when maximum number of flips and maximum flip time are unset?	After the maximum number of flips and maximum flip time, the setup falls to the failover cycle of180 seconds until the route monitor state become UP.
What happens when maximum flip time is over but not the maximum number of flips and there is a route down event?	The setup goes to continuous flip cycle. If maximum flip time is over before the maximum flips are completed, both these parameters are reset to the configured values. As a result, the flip cycle continues forever. The maximum flip time must be configured in such a way that the maximum number of flips can be completed in this configured time.

Configuring Failover Interface Set

Mar 19, 2012

A Failover Interface Set (FIS) is a logical group of interfaces. In an HA configuration, using a FIS is a way to prevent failover by grouping interfaces so that, when one interface fails, other functioning interfaces are still available. A FIS can also be configured for the nodes of a NetScaler cluster.

HA MON interfaces that are not bound to an FIS are known as critical interfaces (CI) because if any of them fails, failover is triggered.

Note: An FIS does not create an active and standby configuration. It also does not prevent bridging loops when connecting to links to the same VLAN.

> **Note**
>
> An FIS does not create an active and standby Interfaces or channels. It also does not prevent bridging loops when connecting to links to the same VLAN

To add an FIS and bind interfaces to it by using the command line interface

At the command prompt, type:

- add fis <name>
- bind fis <name> <ifnum> ...
- show fis <name>

Example

```
> add fis fis1
 Done
> bind fis fis1 1/3 1/5
 Done
```

An unbound interface becomes a critical interface (CI) if it is enabled and HA MON is on.

To unbind an interface from an FIS by using the command line interface

At the command prompt, type:

- unbind fis <name> <ifnum> ...
- show fis <name>

Example

```
> unbind fis fis1 1/3
 Done
```

To configure an FIS by using the configuration utility

Navigate to System > High Availability and, on the Failover Interface Set tab, add a new FIS, or edit an existing FIS.

Updated: 2013-08-28

When the FIS is removed, its interfaces are marked as critical interfaces.

To remove an FIS by using the command line interface

At the command prompt, type:

rm fis <name>

Example

```
> rm fis fis1
  Done
```

To remove an FIS by using the configuration utility

Navigate to System > High Availability and, on the Failover Interface Set tab, delete the FIS.

Understanding the Causes of Failover

Feb 13, 2017

The following events can cause failover in an HA configuration:

1. If the secondary node does not receive a heartbeat packet from the primary for a period of time that exceeds the dead interval set on the secondary. (See Note: 1.)
2. The primary node experiences a hardware failure of its SSL card.
3. The primary node does not receive any heartbeat packets on its network interfaces for three seconds.
4. On the primary node, a network interface that is not part of a Failover Interface Set (FIS) or a Link Aggregation (LA) channel and has the HA Monitor (HAMON) enabled, fails. (See Note: 2.)
5. On the primary node, all interfaces in an FIS fail. (See Note: 2.)
6. On the primary node, an LA channel with HAMON enabled fails. (See Note: 2.)
7. On the primary node, all interfaces fail (see Note: 2). In this case, failover occurs regardless of the HAMON configuration.
8. On the primary node, all interfaces are manually disabled. In this case, failover occurs regardless of the HAMON configuration.
9. You force a failover by issuing the force failover command on either node.
10. A route monitor that is bound to the primary node goes DOWN.

    Note: 1. For more information about setting the dead interval, see Configuring the Communication Intervals. Possible causes for a node not receiving heartbeat packets from a peer node include:

    - A network configuration problem prevents heartbeats from traversing the network between the HA nodes.
    - The peer node experiences a hardware or software failure that causes it to freeze (hang), reboot, or otherwise stop processing and forwarding heartbeat packets.

    Note: 2. In this case, fail means that the interface was enabled but goes to the DOWN state, as can be seen from the show interface command or from the configuration utility. Possible causes for an enabled interface to be in the DOWN state are LINK DOWN and TXSTALL.

Forcing a Node to Fail Over

Mar 19, 2012

You might want to force a failover if, for example, you need to replace or upgrade the primary node. You can force failover from either the primary or the secondary node. A forced failover is not propagated or synchronized. To view the synchronization status after a forced failover, you can view the status of the node.

A forced failover fails in any of the following circumstances:

- You force failover on a standalone system.
- The secondary node is disabled.
- The secondary node is configured to remain secondary.

The NetScaler appliance displays a warning message if it detects a potential issue when you run the force failover command. The message includes the information that triggered the warning, and requests confirmation before proceeding.

You can force a failover on a primary node, secondary node, and when nodes are in listen mode.

- **Forcing Failover on the Primary Node**.
  If you force failover on the primary node, the primary becomes the secondary and the secondary becomes the primary. Forced failover is possible only when the primary node can determine that the secondary node is UP.

  If the secondary node is DOWN, the force failover command returns the following error message: "Operation not possible due to invalid peer state. Rectify and retry."

  If the secondary system is in the claiming state or inactive, it returns the following error message: "Operation not possible now. Please wait for system to stabilize before retrying."

- **Forcing Failover on the Secondary Node**.
  If you run the force failover command from the secondary node, the secondary node becomes primary and the primary node becomes secondary. A force failover can occur only if the secondary node's health is good and it is not configured to stay secondary.

  If the secondary node cannot become the primary node, or if secondary node was configured to stay secondary (using the STAYSECONDARY option), the node displays the following error message: "Operation not possible as my state is invalid. View the node for more information."

- **Forcing Failover When Nodes Are in Listen Mode**.
  When the two nodes of an HA pair are running different versions of the system software, the node running the higher version switches to the listen mode. In this mode, neither command propagation nor synchronization works.

  Before upgrading the system software on both nodes, you should test the new version on one of the nodes. To do this, you need to force a failover on the system that has already been upgraded. The upgraded system then takes over as the primary node, but neither command propagation or synchronization occurs. Also, all connections need to be re-established.

To force failover on a node by using the command line interface

At the command prompt, type:

force HA failover

To force failover on a node by using the configuration utility

Navigate to System > High Availability and, on the Nodes tab, select the node, in the Action list, select Force Failover.

Forcing the Secondary Node to Stay Secondary

Aug 28, 2013

In an HA setup, the secondary node can be forced to stay secondary regardless of the state of the primary node.

For example, suppose the primary node needs to be upgraded and the process will take a few seconds. During the upgrade, the primary node may go down for a few seconds, but you do not want the secondary node to take over; you want it to remain the secondary node even if it detects a failure in the primary node.

When you force the secondary node to stay secondary, it will remain secondary even if the primary node goes down. Also, when you force the status of a node in an HA pair to stay secondary, it does not participate in HA state machine transitions. The status of the node is displayed as STAYSECONDARY.

Forcing the node to stay secondary works on both standalone and secondary nodes. On a standalone node, you must use this option before you can add a node to create an HA pair. When you add the new node, the existing node continues to function as the primary node, and the new node becomes the secondary node.

Note: When you force a system to remain secondary, the forcing process is not propagated or synchronized. It affects only the node on which you run the command.

At the command prompt, type:

set ha node -hastatus STAYSECONDARY

Navigate to System > High Availability, on the Nodes tab, open the local node, and select STAY SECONDARY.

Forcing the Primary Node to Stay Primary

Aug 28, 2013

In an HA setup, you can force the primary node to remain primary even after a failover. You can enable this option either on a primary node in an HA pair or on a standalone system.

On a standalone system, you must run this command before you can add a node to create an HA pair. When you add the new node, it becomes the primary node. The existing node stops processing traffic and becomes the secondary node in the HA pair.

At the command prompt, type:

set ha node -hastatus STAYPRIMARY

Navigate to System > High Availability, on the Nodes tab, open the local node, and select STAY PRIMARY.

Understanding the High Availability Health Check Computation

Mar 19, 2012

The following table summarizes the factors examined in a health check computation:

- State of the CIs
- State of the FISs
- State of the route monitors

The following table summarizes the health check computation.

Table 1. High Availability Health Check Computation

FIS	CI	Route monitor	Condition
N	Y	N	If the system has any CIs, all of those CIs must be UP.
Y	Y	N	If the system has any FISs, all of those FISs must be UP.
Y	Y	Y	If the system has any route monitors configured, all monitored routes must be present in the FIS.

High Availability FAQs

Jul 16, 2013

What are the various ports used to exchange the HA-related information between the nodes in an HA configuration?

In an HA configuration, both nodes use the following ports to exchange HA related information:

- UDP Port 3003, to exchange heartbeat packets.
- Port 3010, for synchronization and command propagation.

What are the conditions that trigger synchronization?

Synchronization is triggered by any of the following conditions:

- The incarnation number of the primary node, received by the secondary, does not match that of the secondary node. Note: Both nodes in an HA configuration maintain a counter called *incarnation number*, which counts the number of configurations in the node's configuration file. Each node sends its incarnation number to each other node in the heartbeat messages. The incarnation number is not incremented for the following commands:
  1. All HA configuration related commands. For example, add ha node, set ha node, and bind ha node.
  2. All Interface related commands. For example, set interface and unset interface.
  3. All channel-related commands. For example, add channel, set channel, and bind channel.
- The secondary node comes up after a restart.
- The primary node becomes secondary after a failover.

What configurations are not synced or propagated in an HA configuration in INC or non-INC mode?

The following commands are neither propagated nor synced to the secondary node:

- All node specific HA configuration commands. For example, add ha node, set ha node, and bind ha node.
- All Interface related configuration commands. For example, set interface and unset interface.
- All channel related configuration commands. For example, add channel, set channel, and bind channel.

What configurations are not synced nor propagated in an HA configuration in INC mode?

The following configurations are not synced or propagated. Each node has its own.

- MIPs
- SNIPs
- VLANs
- Routes (except LLB routes)
- Route monitors
- RNAT rules (except any RNAT rule with VIP as the NAT IP)
- Dynamic routing configurations.

Does a configuration added to the secondary node get synchronized on the primary?

No, a configuration added to the secondary node is not synchronized to the primary.

What could be the reason for both nodes claiming to be the primary in an HA configuration?

The most likely reason is that the primary and secondary nodes are both healthy but the secondary does not receive the heartbeat packets from the primary. The problem could be with the network between the nodes.

Does an HA configuration run into any issues if you deploy the two nodes with different system clock settings?

Different system-clock settings on the two nodes can cause the following issues:

- The time stamps in the log file entries do not match. This situation makes it difficult to analyze the log entries for any issues.
- After a failover, you might have problems with any type of cookie based persistence for load balancing. A significant difference between the times can cause a cookie to expire sooner than expected, resulting in termination of the persistence session.
- Similar considerations apply to any time related decisions on the nodes.

What are the conditions for failure of the *force HA sync* command?

Forced synchronization fails in any of the following circumstances:

- You force synchronization when synchronization is already in progress.
- You force synchronization on a standalone NetScaler appliance.
- The secondary node is disabled.
- HA synchronization is disabled on the current secondary node.
- HA propagation is disabled on the current primary node and you force synchronization from the primary.

What are the conditions for failure of the *sync HA files* command?

Synchronizing configuration files fail in either of the following circumstances:

- On a standalone system.
- With the secondary node disabled.

In an HA configuration, if the secondary node takes over as the primary, does it switch back to secondary status if the original primary comes back online?

No. After the secondary node takes over as the primary, it remains as primary even if the original primary node comes back online again. To interchange the primary and secondary status of the nodes, run the *force failover* command.

What are the conditions for failure of the *force failover* command?

A forced failover fails in any of the following circumstances:

- You force failover on a standalone system.
- The secondary node is disabled.
- The secondary node is configured to remain secondary.
- The primary node is configured to remain primary.
- The state of the peer node is unknown.

Troubleshooting High Availability Issues

Jul 29, 2013

The most common high availability issues involve the high availability feature not working at all, or working only intermittently. Following are common high availability issues, and probable causes and resolutions.

- Issue
  The inability of the NetScaler appliances to pair the NetScaler appliances in a high availability setup.
  - Cause
    Network connectivity

    Resolution

    Verify that both the appliances are connected to the switch and the interfaces are enabled.

  - Cause
    Mismatch in the Password for the default Administrator account

    Resolution

    Verify that the password on both the appliances is the same.

  - Cause
    IP conflict

    Resolution

    Verify that both the appliances have unique NetScaler IP (NSIP) address. The appliances should not have the same NSIP address.

  - Cause
    Node ID mismatch

    Resolution

    Verify that the Node ID Configuration on both the appliances is unique. The appliances should not have the same Node ID configuration. Additionally, you must assign value for a Node ID between 1 and 64.

  - Cause
    Mismatch in the password of the RPC node

    Resolution

    Verify that both the nodes have the same RPC node password.

  - Cause
    An administrator has disabled the remote node

    Resolution

    Enable the remote node.

- Cause
  The Firewall application has blocked the heartbeat packets

  Resolution

  Verify that the UDP port 3003 is allowed.

- Issue
  Both the appliances claim to be the primary appliance.
  - Cause
    Missing heartbeat packets between the appliances

    Resolution

    Verify that the UDP port 3003 is not blocked for communication between the appliances.

- Issue
  The NetScaler appliance is not able to synchronize the configuration.
  - Cause
    A Firewall application is blocking the required port.

    Resolution

    Verify that the UDP port 3010 (or UDP port 3008 with secure synchronization) is not blocked for communication between the appliances.

  - Cause
    An administrator has disabled synchronization.

    Resolution

    Enable synchronization on the appliance that has the issue.

  - Cause
    Different NetScaler releases or builds are installed on appliances.

    Resolution

    Upgrade the appliances to the same NetScaler release or build.

- Issue
  Command propagation fails between the appliances.
  - Cause
    A Firewall application is blocking the port.

    Resolution

    Verify that the UDP port 3011 (or UDP port 3009 with secure propagation) is not blocked for communication between the appliances.

  - Cause
    An administrator has disabled command propagation.

Resolution

Enable command propagation on the appliance that has the issue.

- Cause
  Different NetScaler releases or builds are installed on appliances.

  Resolution

  Upgrade the appliances to the same NetScaler release or build.

- Issue
  The NetScaler appliances in the high availability pair are unable to run the force failover process.
  - Cause
    The Secondary node is disabled.

    Resolution

    Enable the secondary node.

  - Cause
    The Secondary node is configured to stay secondary.

    Resolution

    Set the secondary high availability status of the secondary node to Enable from Stay Secondary.

- Issue
  The secondary appliance does not receive any traffic after the failover process.
  - Cause
    The upstream router does not understand GARP messages of NetScaler appliance.

    Resolution

    Configure Virtual MAC (VMAC) address on the secondary appliance.

Managing High Availability Heartbeat Messages on a NetScaler Appliance

Jul 07, 2016

The two nodes in a high availability configuration send and receive heartbeat messages to and from each other on all interfaces that are enabled. The heartbeat messages flow regardless of the HA MON setting on these interfaces. If NSVLAN or SYNCVLAN or both are configured on an appliance, the heartbeat messages flow only through the enabled interfaces that are part of the NSVLAN and SYNCVLAN.

If a node does not receive the heartbeat messages on an enabled interface, it sends critical alerts to the specified Command Center and SNMP managers. These critical alerts give false alarms and draw unnecessary attention from the administrators for interfaces that are not configured as part of the connections to the peer node.

To resolve this issue, the HAHeartBeat option for interfaces and channels is used for enabling or disabling HA heartbeat-message flow on them.

To manage the high availability heartbeat messages on an interface by using the command line interface

At the command prompt, type:

- **set interface** <ID> [-**HAHeartBeat** (**ON** | **OFF**)]
- **show interface** <ID>

To manage the high availability heartbeat messages on a channel by using the command line interface

At the command prompt, type:

- **set channel** <ID> [-**HAHeartBeat** (**ON** | **OFF**)]
- **show channel** <ID>

To manage the high availability heartbeat messages for an interface by using the configuration utility

1. Navigate to **System** > **Network** > **Interfaces**.
2. Enable or disable the **HA Heart Beat** parameter.

To manage the high availability heartbeat messages on a channel by using the configuration utility

1. Navigate to **System** > **Network** > **Channels**.
2. Enable or disable the **HA Heart Beat** parameter.

TCP Optimization

Sep 27, 2017

TCP uses the following optimization techniques and congestion control strategies (or algorithms) to avoid network congestion in data transmission.

Congestion Control Strategies

The Transmission Control Protocol (TCP) has long been used to establish and manage Internet connections, handle transmission errors, and smoothly connect web applications with client devices. But network traffic has become more difficult to control, because packet loss does not depend only on the congestion in the network, and congestion does not necessarily cause packet loss. Therefore, to measure congestion, a TCP algorithm should focus on both packet loss and bandwidth.

TCP Fast Recovery mechanisms reduce web latency caused by packet losses. The new Proportional Rate Recovery (PRR) algorithm is a fast recovery algorithm that evaluates TCP data during a loss recovery. It is patterned after Rate-Halving, by using the fraction that is appropriate for the target window chosen by the congestion control algorithm. It minimizes window adjustment, and the actual window size at the end of recovery is close to the Slow-Start threshold (ssthresh).

TCP Fast Open (TFO) is a TCP mechanism that enables speedy and safe data exchange between a client and a server during TCP's initial handshake. This feature is available as a TCP option in the TCP profile bound to a virtual server of a NetScaler appliance. TFO uses a TCP Fast Open Cookie (a security cookie) that the NetScaler appliance generates to validate and authenticate the client initiating a TFO connection to the virtual server. By using the TFO mechanism, you can reduce an application's network latency by the time required for one full round trip, which significantly reduces the delay experienced in short TCP transfers.

How TFO works

When a client tries to establish a TFO connection, it includes a TCP Fast Open Cookie with the initial SYN segment to authenticate itself. If authentication is successful, the virtual server on the NetScaler appliance can include data in the SYN-ACK segment even though it has not received the final ACK segment of the three-way handshake. This saves up to one full round-trip compared to a normal TCP connection, which requires a three-way handshake before any data can be exchanged.

A client and a backend server perform the following steps to establish a TFO connection and exchange data securely during the initial TCP handshake.

1. If the client does not have a TCP Fast Open Cookie to authenticate itself, it sends a Fast Open Cookie request in the SYN packet to the virtual server on the NetScaler appliance.
2. If the TFO option is enabled in the TCP profile bound to the virtual server, the appliance generates a cookie (by encrypting the client's IP address under a secret key) and responds to the client with a SYN-ACK that includes the generated Fast Open Cookie in a TCP option field.
3. The client caches the cookie for future TFO connections to the same virtual server on the appliance.
4. When the client tries to establish a TFO connection to the same virtual server, it sends SYN that includes the cached

Fast Open Cookie (as a TCP option) along with HTTP data.

5. The NetScaler appliance validates the cookie, and if the authentication is successful, the server accepts the data in the SYN packet and acknowledges the event with a SYN-ACK, TFO Cookie, and HTTP Response.

   Note: If the client authentication fails, the server drops the data and acknowledges the event only with a SYN indicating a session timeout.

1. On the server side, if the TFO option is enabled in a TCP profile bound to a service, the NetScaler appliance determines whether the TCP Fast Open Cookie is present in the service to which it is trying to connect.
2. If the TCP Fast Open Cookie is not present, the appliance sends a cookie request in the SYN packet.
3. When the backend server sends the Cookie, the appliance stores the cookie in the server information cache.
4. If the appliance already has a cookie for the given destination IP pair, it replaces the old cookie with the new one.
5. If the cookie is available in the server information cache when the virtual server tries to reconnect to the same backend server by using the same SNIP address, the appliance combines the data in SYN packet with the cookie and sends it to the backend server.
6. The backend server acknowledges the event with both data and a SYN.

   Note: If the server acknowledges the event with only a SYN segment, the NetScaler appliance immediately resends the data packet after removing the SYN segment and the TCP options from the original packet.

Configuring TCP Fast Open

To use the TCP Fast Open (TFO) feature, enable the TCP Fast Open option in the relevant TCP profile and set the TFO Cookie Timeout parameter to a value that suits the security requirement for that profile.

To enable or disable TFO by using the command line

At the command prompt, type one of the following commands to enable or disable TFO in a new or existing profile.

Note: The default value is DISABLED.

```
add tcpprofile <TCP Profile Name> - tcpFastOpen ENABLED | DISABLED

set tcpprofile <TCP Profile Name> - tcpFastOpen ENABLED | DISABLED

unset tcpprofile <TCP Profile Name> - tcpFastOpen

Examples

add tcpprofile Profile1 – tcpFastOpen

Set tcpprofile Profile1 – tcpFastOpen Enabled

unset tcpprofile Profile1 – tcpFastOpen
```

To set TCP Fast Open cookie timeout value by using the command line interface

At the command prompt, type:

```
set tcpparam –tcpfastOpenCookieTimeout <Timeout Value>

Example

set tcpprofile –tcpfastOpenCookieTimeout 30secs
```

To configure the TCP Fast Open by using the NetScaler GUI

1. Navigate to **Configuration** > **System** > **Profiles** > and then click **Edit** to modify a TCP profile.
2. On the **Configure TCP Profile** page, select the **TCP Fast Open** checkbox.
3. Click **OK** and then **Done**.

To Configure the TCP Fast Cookie timeout value by using the NetScaler GUI

Navigate to **Configuration** > **System** > **Settings** > **Change TCP Parameters** and then **Configure TCP Parameters** page to set the TCP Fast Open Cookie timeout value.

A new TCP profile parameter, hystart, enables the Hystart algorithm, which is a slow-start algorithm that dynamically determines a safe point at which to terminate (ssthresh). It enables a transition to congestion avoidance without heavy packet losses. This new parameter is disabled by default.

If congestion is detected, Hystart enters a congestion avoidance phase. Enabling it gives you better throughput in high-speed networks with high packet loss. This algorithm helps maintain close to maximum bandwidth while processing transactions. It can therefore improve throughput.

Configuring TCP Hystart

To use the Hystart feature, enable the Cubic Hystart option in the relevant TCP profile.

To configure Hystart by using the command line interface (CLI)

At the command prompt, type one of the following commands to enable or disable Hystart in a new or existing TCP profile.

```
add tcpprofile <profileName> -hystart ENABLED

set tcpprofile <profileName> -hystart ENABLED

unset tcprofile <profileName> -hystart

Examples

add tcpprofile Profile1 – tcpFastOpen

Set tcpprofile Profile1 – tcpFastOpen Enabled

unset tcpprofile Profile1 – tcpFastOpen
```

To configure Hystart support by using the NetScaler GUI

1. Navigate to **Configuration** > **System** > **Profiles** > and click **Edit** to modify a TCP profile.
2. On the **Configure TCP Profile** page, select the **Cubic Hystart** check box.
3. Click **OK** and then **Done**.

It is observed that TCP control mechanisms can lead to a bursty traffic flow on high speed mobile networks with a negative impact on the overall network efficiency. Due to mobile network conditions such as congestion or Layer-2 retransmission

of data, TCP acknowledgements arrive clumped at the sender triggering a burst of transmission. These group of consecutive packets sent with a short inter-packet gaps it is called TCP packet burst. To overcome the bustiness in traffic, the NetScaler appliance uses a TCP Burst Rate Control technique. This technique evenly spaces data into the network for an entire round-trip-time so that the data is not sent into a burst. By using this burst rate control technique, you can achieve better throughput and lower packet drop rates.

How TCP Burst Rate Control Works

In a NetScaler appliance, this technique evenly spreads the transmission of a packets across the entire duration of the round-trip-time (RTT). This is achieved by using a TCP stack and network packet scheduler that identifies the various network conditions to output packets for ongoing TCP sessions in order to reduce the bursts.

At the sender, instead of transmitting packets immediately upon receipt of an acknowledgment, the sender can delay transmitting packets to spread them out at the rate defined by scheduler (Dynamic configuration) or by the TCP profile (Fixed configuration).

Configuring TCP Burst Rate Control

To use the TCP Burst Rate Control feature, enable the TCP Burst Rate Control option in the relevant TCP profile and set the burst rate control parameters.

To enable or disable TCP Burst Rate Control by using the command line

At the command prompt, set one of the following TCP Burst Rate Control commands are configured in a new or existing profile.

Note: The default value is DISABLED.

```
add tcpprofile <TCP Profile Name> -burstRateControl Disabled | Dynamic | Fixed

set tcpprofile <TCP Profile Name> -burstRateControl Disabled | Dynamic | Fixed

unset tcpprofile <TCP Profile Name> -burstRateControl Disabled | Dynamic | Fixed
```

where

Disabled – If the Burst rate control is disabled, then a NetScaler appliance does not perform burst management other than the maxBurst setting.

Fixed – If the TCP burst rate control is Fixed, the appliance uses the TCP Connection Payload Send Rate value mentioned in the TCP Profile.

Dynamic – If the Burst Rate Control is “Dynamic” the connection is being regulated based on various network conditions to reduce TCP bursts. This mode works only when the TCP connection is in ENDPOINT mode. When Dynamic Burst Rate control is enabled the maxBurst parameter of the TCP profile is not in effect.

```
add tcpProfile  profile1 -burstRateControl Disabled

set tcpProfile profile1 -burstRateControl Dynamic

unset tcpProfile profile1 -burstRateControl Fixed
```

At the command prompt, type:

```
set ns tcpprofile nstcp_default_profile –burstRateControl <type of burst rate control> –tcprate <TCP rate> -rateqmax <maximum bytes in
```

```
T1300-10-2> show ns tcpprofile nstcp_default_profile

        Name: nstcp_default_profile

        Window Scaling status:  ENABLED

        Window Scaling factor: 8

        SACK status: ENABLED

        MSS: 1460

        MaxBurst setting: 30 MSS
```

MaxBurst setting: 30 MSS

Accept RST with last acknowledged sequence number: ENABLED

SYN spoof protection: ENABLED

TCP Explicit Congestion Notification: DISABLED

Multipath TCP: DISABLED

Multipath TCP drop data on pre-established subflow: DISABLED

Multipath TCP fastopen: DISABLED

Multipath TCP session timeout: 0 seconds

DSACK: ENABLED

ACK Aggregation: DISABLED

FRTO: ENABLED

TCP Max CWND : 4000000 bytes

FACK: ENABLED

TCP Optimization mode: ENDPOINT

TCP Fastopen: DISABLED

HYSTART: DISABLED

TCP dupack threshold: 3
```

```
Burst Rate Control: Dynamic

TCP Rate: 0

TCP Rate Maximum Queue: 0
```

1. Navigate to **Configuration** > **System** > **Profiles** > and then click **Edit** to modify a TCP profile.
2. On the **Configure TCP Profile** page, select **TCP Burst Control** option from the drop-down list.
3. Click **OK** and then **Done**.

Optimization Techniques

TCP uses the following optimization techniques and methods for optimized flow controls.

Network traffic today is more diverse and bandwidth-intensive than ever before. With the increased traffic, the effect that Quality of Service (QoS) has on TCP performance is significant. To enhance QoS, you can now configure AppQoE policies with different TCP profiles for different classes of network traffic. The AppQoE policy classifies a virtual server's traffic to associate a TCP profile optimized for a particular type of traffic, such as 3G, 4G, LAN, or WAN.

To use this feature, create a policy action for each TCP profile, associate an action with AppQoE policies, and bind the policies to the load balancing virtual servers.

For information about using subscriber attributes to perform TCP optimization, see Policy-based TCP Profile.

Configuring Policy Based TCP Profile Selection

Configuring policy based TCP profile selection consists of the following tasks:

- Enabling AppQoE. Before configuring the TCP profile feature, you must enable the AppQoE feature.
- Adding AppQoE Action. After enabling the AppQoE feature, configure an AppQoE action with a TCP profile.
- Configuring AppQoE based TCP Profile Selection. To implement TCP profile selection for different classes of traffic, you must configure AppQoE policies with which your NetScaler ADC can distinguish the connections and bind the correct AppQoE action to each policy.
- Binding AppQoE Policy to Virtual Server. Once you have configured the AppQoE policies, you must bind them to one or more load balancing, content switching, or cache redirection virtual servers.

Configuring using the command line interface

To enable AppQoE by using the command line interface

At the command prompt, type the following commands to enable the feature and verify that it is enabled:

- enable ns feature appqoe
- show ns feature

At the command prompt, type the following AppQoE action command with tcpprofiletobind option.

```
add appqoe action <name> [-priority <priority>] [-respondWith ( ACS | NS ) [<CustomFile>] [-altContentSvcName <string>] [-altCont

show appqoe action
```

To configure an AppQoE policy by using the command line interface

At the command prompt, type:

```
add appqoe policy <name> -rule <expression> -action <string>
```

To bind an AppQoE policy to load balancing, cache redirection or content switching virtual servers by using the command line interface

At the command prompt, type:

```
bind cs vserver cs1 -policyName <appqoe_policy_name> -priority <priority>

bind lb vserver <name> - policyName <appqoe_policy_name> -priority <priority>

bind cr vserver <name> -policyName <appqoe_policy_name> -priority <priority>
```

```
```

```
add ns tcpProfile tcp1 -WS ENABLED -SACK ENABLED -WSVal 8 -nagle ENABLED -maxBurst 30 -initialCwnd 16 -oooQSize 15000 -minF

add appqoe action appact1 -priority HIGH -tcpprofile tcp1

add appqoe policy apppol1 -rule "client.ip.src.eq(10.102.71.31)" -action appact1

bind lb vserver lb2 -policyName apppol1 -priority 1 -gotoPriorityExpression END -type REQUEST

bind cs vserver cs1 -policyName apppol1 -priority 1 -gotoPriorityExpression END -type REQUEST
```

Configuring Policy based TCP Profiling using the NetScaler GUI

To enable AppQoE by using the NetScaler GUI

1. Navigate to **System** > **Settings**.
2. In the details pane, click **Configure Advanced Features.**
3. In the **Configure Advanced Features** dialog box, select the **AppQoE** check box.
4. Click **OK**.

To configure AppQoE policy by using the NetScaler GUI

1. Navigate to **App-Expert** > **AppQoE** > **Actions**.
2. In the details pane, do one of the following:
3. To create a new action, click **Add**.
4. To modify an existing action, select the action, and then click **Edit**.
5. In the **Create AppQoE Action** or the **Configure AppQoE Action** screen, type or select values for the parameters. The contents of the dialog box correspond to the parameters described in "Parameters for configuring the AppQoE Action" as follows (asterisk indicates a required parameter):
   1. Name—name
   2. Action type—respondWith
   3. Priority—priority
   4. Policy Queue Depth—polqDepth
   5. Queue Depth—priqDepth
   6. DOS Action—dosAction
6. Click **Create**.

To bind AppQoE policy by using the NetScaler GUI

1. Navigate to **Traffic Management** > **Load Balancing** > **Virtual Servers**, select a server and then click **Edit**.
2. In the **Policies** section and click (+) to bind an AppQoE policy.
3. In the **Policies** slider, do the following:
   1. Select a policy type as AppQoE from the drop-down list.

2. Select a traffic type from the drop-down list.
4. In the **Policy Binding** section, do the following:
   1. Click **New** to create a new AppQoE policy.
   2. Click **Existing Policy** to select an AppQoE policy from the drop-down list.
5. Set the binding priority and click **Bind** to the policy to the virtual server.
6. Click **Done**.

TCP performance slows down when multiple packets are lost in one window of data. In such a scenario, a Selective Acknowledgement (SACK) mechanism combined with a selective repeat retransmission policy overcomes this limitation. For every incoming out-of-order packet, you must generate a SACK block.

If the out-of-order packet fits in the reassembly queue block, insert packet info in the block, and set the complete block info as SACK-0. If an out-of-order packet does not fit into reassembly block, send the packet as SACK-0 and repeat the earlier SACK blocks. If an out-of-order packet is a duplicate and packet info is set as SACK-0 then D-SACK the block.

Note: A packet is considered as D-SACK if it is an acknowledged packet, or an out of order packet which is already received.

A NetScaler appliance can handle client reneging during SACK based recovery.

In a NetScaler appliance, if the memory usage threshold is set to 75 percent instead of using the total available memory, it causes new TCP connections to bypass TCP optimization.

In a non-endpoint mode, when you send DUPACKS, if SACK blocks are missing for few out of order packets, triggers additional retransmissions from the server.

The following SNMP ids have been added to a NetScaler appliance to track number of connections bypassed TCP optimization due to overload.

1. 1.3.6.1.4.1.5951.4.1.1.46.131 (tcpOptimizationEnabled). To track the total number of connections enabled with TCP optimization.
2. 1.3.6.1.4.1.5951.4.1.1.46.132 (tcpOptimizationBypassed). To track the total number of connections bypassed TCP Optimization.

To maximize TCP performance, a NetScaler appliance can now dynamically adjust the TCP receive buffer size.

NITRO API

Oct 14, 2015

The NetScaler NITRO protocol allows you to configure and monitor the NetScaler appliance programmatically by using Representational State Transfer (REST) interfaces. Therefore, NITRO applications can be developed in any programming language. Additionally, for applications that must be developed in Java or .NET or Python, NITRO APIs are exposed through relevant libraries that are packaged as separate Software Development Kits (SDKs).

Important

- XML API are deprecated from NetScaler 10.5 onwards.

- Until specified otherwise, this NITRO documentation applies to NetScaler versions 11.0 and 10.5.

To use NITRO, you must have a basic understanding of the NetScaler appliance and you must make sure that the client application has the following:

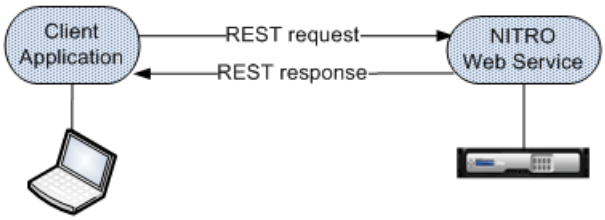
- Access to a NetScaler appliance, version 9.2 or later.
- To use REST interfaces, you must have a system to generate HTTP or HTTPS requests (payload in JSON format) to the NetScaler appliance. You can use any programming language or tool.
- For Java clients, you must have a system where Java Development Kit (JDK) 1.5 or later is available. The JDK can be downloaded from http://www.oracle.com/technetwork/java/javase/downloads/index.html.
- For .NET clients, you must have a system with .NET framework 3.5 or later installed. The .NET framework can be downloaded from http://www.microsoft.com/downloads/en/default.aspx.
- The Python SDK is available from NetScaler 10.5 onwards. For Python clients, you must have a system with Python 2.7 or above version and the Requests library (available in <NITRO_SDK_HOME>/lib) installed. The NITRO library must be installed on the client path. For installation instructions, read the <NITRO_SDK_HOME>/README.txt file.

The NITRO package is available as a tar file on the **Downloads** page of the configuration utility of the NetScaler appliance. You must download and untar the file to a folder on your local system. This folder is referred to as <NITRO_SDK_HOME> in this documentation.
The folder contains the NITRO libraries in the lib subfolder. The libraries must be added to the client application classpath to access NITRO functionality. The <NITRO_SDK_HOME> folder also provides samples and documentation that can help you understand the NITRO SDK.

Note

- The REST package contains only documentation for using the REST interfaces.
- For the Python SDK, the library must be installed on the client path. For installation instructions, read the <NITRO_SDK_HOME>/README.txt file.

The NITRO infrastructure consists of a client application and the NITRO Web service running on a NetScaler appliance. The communication between the client application and the NITRO web service is based on REST architecture using HTTP or HTTPS.



As shown in the above figure, a NITRO request is executed as follows:

1. The client application sends REST request message to the NITRO web service. When using the SDKs, an API call is translated into the appropriate REST request message.
2. The web service processes the REST request message.
3. The NITRO web service returns the corresponding REST response message to the client application. When using the SDKs, the REST response message is translated into the appropriate response for the API call.

To minimize traffic on the NetScaler network, you retrieve the whole state of a resource from the server, make modifications to the state of the resource locally, and then upload it back to the server in one network transaction. For example, to update a load balancing virtual server, you must retrieve the object, update the properties, and then upload the changed object in a single transaction.

Note: Local operations on a resource (changing its properties) do not affect its state on the server until the state of the object is explicitly uploaded.

NITRO APIs are synchronous in nature. This means that the client application waits for a response from the NITRO web service before executing another NITRO API.

REST Web Services

Jan 27, 2016

REST (REpresentational State Transfer) is an architectural style based on simple HTTP requests and responses between the client and the server. REST is used to query or change the state of objects on the server side. In REST, the server side is modeled as a set of entities where each entity is identified by a unique URL.

For information on the NITRO SDKs, see Java, .NET, and Python API.

The general format for NITRO URLs is as follows:

- **For configurations.** http://<netscaler-ip-address>/nitro/v1/config/<resource-type>
- **For retrieving statistics.** http://<netscaler-ip-address>/nitro/v1/stat/<resource-type>

For example, for a load balancing virtual server, <resource-type> can be replaced by lbvserver.

Important

From NetScaler 10.1 version onwards, the following Content-Type is supported:

Content-Type:application/json.

However, content types such as "application/x-www-form-urlencoded" and of the form "application/vnd.com.citrix.netscaler" that were supported in NetScaler 9.3 and earlier versions can also be used. You must make sure that the payload is the same as used in earlier versions.

The payloads provided in this documentation are applicable only for the "application/json" Content-Type.

For NetScaler version below 11.0 67.X and version 10.5 63.X and later, if you use "application/json" as the Content-Type the request/response format is different depending on the HTTP method used.

For PUT requests, provide warning and onerror parameters in the request payload rather than in the URI or Header.

For example:

```
{
  "params":
  {
   "warning":"yes",
   "onerror":"continue"
  },
  "lbvserver":[
   {
    "name":<String_value>,
    ...
   }
   ....
  ]
}
```

For PUT and DELETE operations, read the warning message from response payload rather than from X-NITRO-WARNING and note

that status code is set to "200 Ok" instead of "209 NetScaler specific warning".

For example:

```
{
  errorcode: 1067,
  message: "Feature(s) not enabled [LB]",
  severity: "WARNING"
}
```

Some points to remember:

- In addition to the CRUD operations (Create, Read, Update, and Delete), resources (such as lbvserver) can support other operations or actions. These operations use the HTTP POST method, with the URL specifying the operation to be performed and the request body specifying the parameters for that operation.
- All NITRO operations are logged in the /var/log/nitro.log file on the NetScaler appliance.

For more information on the REST objects and the usage, see the documentation provided in the <NITRO_SDK_HOME>/index.html file.

Connecting to the NetScaler Appliance

Feb 09, 2016

The first step towards using NITRO is to establish a session with the NetScaler appliance and then authenticate the session by using the NetScaler administrator's credentials. You must specify the username and password in the login object. The session ID that is created must be specified in the request header of all further operations in the session.

Note:

- You must have a user account on the appliance to log on to it. The configuration operations that you can perform are limited by the administrative roles assigned to your account.
- To ensure secure communication, use the HTTPS protocol in NITRO requests.
- Instead of creating a NITRO session, you can log on to the NetScaler appliance while performing individual operations. To do this, you must specify the username and password in the **request header** of the NITRO request as follows:
  X-NITRO-USER:<username>
  X-NITRO-PASS:<password>
  Content-Type:application/json

For example, to connect and create a session with a NetScaler appliance with NSIP address 10.102.29.60 by using the HTTP protocol:

- **Request:**

  HTTP Method

  POST

  URL

  http://10.102.29.60/nitro/v1/config/login

  Request Headers

  Content-Type:application/json

  Request Payload

```
{
   "login":
   {
      "username":"admin",
      "password":"verysecret"
   }
}
```

- **Response:**

  HTTP Status Code on Success

  201 Created

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

  Response Header

  Set-Cookie:
  NITRO_AUTH_TOKEN=<tokenvalue>;

path=/nitro/v1

Modifying the Session Timeout

You can modify the timeout period by specifying a new timeout period (in seconds) in the login object. For example, to modify the timeout period to 60 minutes:

```
{
   "login":
   {
      "username":"admin",
      "password":"verysecret",
      "timeout":"3600"
   }
}
```

Some points to note with regards to session timeout for NetScaler 10.5 and later versions:

- When restricted timeout param is enabled, NITRO, by default, uses the timeout value that is configured for the logged in user. You can customize this value but it must be limited to the value specified for the user. If no value is specified for the user, the default timeout value of 15 minutes is used.
- When restricted timeout param is not enabled, NITRO uses the default value of 30 minutes as session timeout.

Enabling NetScaler Features and Modes

Apr 10, 2015

Some NetScaler features and modes are disabled by default and therefore must be enabled before they can be configured. To enable a NetScaler feature or mode, specify the action as "enable" in the URL query string, and in the request payload, specify the feature or mode to be enabled.

For example, to enable the load balancing and content switching features:

- **Request:**

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/nsfeature?action=enable

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

  Content-Type:application/json

  Request Payload

```
{
   "nsfeature":
   {
      "feature":
      [
         "LB",
         "CS"
      ]
   }
}
```

- **Response:**

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

For example, to enable the L2 and fast ramp modes:

- **Request:**

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/nsmode?action=enable

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

Content-Type:application/json

Request Payload

```
{
   "nsmode":
   {
      "mode":
      [
         "L2",
         "FR"
      ]
   }
}
```

- Response:

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Note: To disable a feature or mode, in the URL query string, specify the action as "disable".

Saving NetScaler Configurations

Apr 10, 2015

To make sure that the configurations persist on rebooting the appliance, you must save the NetScaler configurations. To save the configurations, specify the action as "save" in the URL query string.

To save the configurations:

- Request:

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/nsconfig?action=save

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>
  Content-Type:application/json

  Request Payload

  ```
  {
    "nsconfig":
    {}
  }
  ```

- Response:

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

General API Usage

Apr 01, 2015

A NetScaler appliance has multiple features, and each feature has multiple resources. Each NetScaler resource, depending on the operation to be performed on it, has a unique URL associated with it. URLs for configuration operations have the following format:

http://<netscaler-ip-address>/nitro/v1/config/<resource_type>/<resource_name>.

For example, to access the lbvserver named MyFirstLbVServer on a NetScaler with IP 10.102.29.60, the URL is:

http://10.102.29.60/nitro/v1/config/lbvserver/MyFirstLbVServer.

This section explains, in general, the different types of operations that can be performed on the NetScaler appliance by using NITRO API.

Before going into the details of these operations, you must be aware of the following functionality:

- You can use the "action" query parameter in the URL to perform operations such as save, enable, disable, and kill sessions.
- You can use the "attrs", "filter", "args", "count" and other query parameters when retrieving NetScaler resources. For more information, see Retrieving Details of NetScaler Resources.
- You can perform bulk operations and thus minimize network traffic. To perform a bulk operation, specify the required parameters in the same request payload. You can also control the behavior of a bulk operation in case of failure of some operations. To do this, in the request header, specify the appropriate value for the X-NITRO-ONERROR parameter. For more information, see Performing Bulk Operations.
- NetScaler NITRO clearly shows the errors so that corrective actions can be taken. For more information, see Error Handling.

Adding a NetScaler Resource

Apr 10, 2015

To create a new resource (for example, an lbvserver) on the appliance, specify the resource name and other related arguments in the specific resource object.

For example, to create an load balancing virtual server named MyFirstLbVServer:

- Request:

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/lbvserver

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

  Content-Type:application/json

  Request Payload

```
{
   "lbvserver":
   {
      "name":"MyFirstLbVServer",
      "servicetype":"http"
   }
}
```

- Response:

  HTTP Status Code on Success

  201 Created

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Enabling a NetScaler Resource

Apr 10, 2015

To enable a resource on the NetScaler appliance, specify the action as "enable" in the URL query string, and in the request payload, specify the resource to be enabled.

For example, to enable a load balancing virtual server named MyFirstLbVServer:

- Request:

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/lbvserver?action=enable

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>
  Content-Type:application/json

  Request Payload

```
{
   "lbvserver":
   {
      "name":"MyFirstLbVServer"
   }
}
```

- Response:

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Note: To disable a resource, in the URL query string, specify the action as "disable".

Getting the Count of NetScaler Resources

Apr 10, 2015

To get a count of a specific resource type, in the URL specify the count query parameter as "yes".

For example, to get a count of all the load balancing virtual servers:

- Request:

  HTTP Method

  GET

  URL

  http://<netscaler-ip-address>/nitro/v1/config/lbvserver?count=yes

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

  Accept:application/json

- Response:

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

  Response Header

  Content-Type:application/json

  Response Payload

```
{
   "lbvserver":
   [
      {
         "__count": 4
      }
   ]
}
```

Retrieving Details of NetScaler Resources

Apr 10, 2015

NITRO provides multiple approaches using which you can retrieve resources and their relevant details. The following table explains each of these approaches with the required URL.

Note: A sample format of the request and response is provided below the table.

Retrieving all details of all resources of a specific type	In the URL, specify the type of resource for which you want to retrieve the details. For example, to retrieve all details of load balancing virtual servers available on a NetScaler appliance. http://<netscaler-ip-address>/nitro/v1/config/lbvserver
Retrieving all details of a specific resource	In the URL, specify the name of resource for which you want to retrieve the details. For example, to retrieve all details of a load balancing virtual server named MyFirstLbVServer: http://<netscaler-ip-address>/nitro/v1/config/lbvserver/MyFirstLbVServer
Retrieving summary or detailed view of resources	In the URL, use the "view" query parameter to specify whether you want to view the summary (mandatory parameters) or detail (all parameters). For example, to view the mandatory parameters for all load balancing virtual servers: http://<netscaler-ip-address>/nitro/v1/config/lbvserver?view=summary Note: By default, the retrieved results are displayed in detail view (?view=detail).
Retrieving all details of resources that have multiple unique identifiers	In the URL, specify the type of resource and use the "args" query parameter to specify the unique attributes and the values for those attributes. For example, to get the application firewall profiles that have unique identifiers "name" and "starturl" as appfw1 and aa respectively. http://<netscaler-ip-address>/nitro/v1/config/appfwprofile? args=name:appfw1,starturl:aa
Retrieving specific details of all resources of a specific type	In the URL, specify the type of the resource and use the "attrs" query parameter to specify the resource details that you want to retrieve. For example, to retrieve the "name" and "lbmethod" of all load balancing virtual servers: http://<netscaler-ip-address>/nitro/v1/config/lbvserver?attrs=name,lbmethod
Retrieving specific details of a specific	In the URL, specify the type and name of the resource and use the "attrs" query parameter to specify the resource details that you want to retrieve.

resource	For example, to retrieve the "name" and "lbmethod" of a load balancing virtual server named "MyFirstLbVServer": http://<netscaler-ip-address>/nitro/v1/config/lbvserver/MyFirstLbVServer?attrs=name,lbmethod
Filtering the retrieved resources	In the URL, specify the type of resource and use the "filter" query parameter to specify the attribute(s) and the value(s) of the attributes. The resources fetched will be filtered based on the filter criteria. Note: The filter query parameter supports the use of PCRE regular expressions. For example, to filter the load balancing virtual servers where the "lbmethod" is ROUNDROBIN. http://<netscaler-ip-address>/nitro/v1/config/lbvserver?filter=lbmethod:ROUNDROBIN
Retrieving resources in paginated manner	If the request is likely to result in a large number of resources, you can divide the results into pages and retrieve them page by page (paginated). For example, if you are retrieving all the 53 load balancing virtual servers of a NetScaler appliance, instead of retrieving all 53 in one response, you can configure the results to be divided into 6 pages each having 10 results. In the URL, specify the name of the resource and use the following query parameters: • "pageno" - The page number to be displayed. • "pagesize" - The number of resources to be displayed in each page. For example, to retrieve the load balancing virtual servers in a paginated form, first get a count (using the "count" query parameter shown in below row) of the load balancing virtual servers. Then, accordingly specify the number of results for each page and then specify the page number to be displayed. http://<netscaler-ip-address>/nitro/v1/config/lbvserver?pagesize=10&pageno=3

For example, to retrieve only the name and load balancing method of all load balancing virtual servers on a NetScaler:

- Request:

  HTTP Method

  GET

  URL

  http://<netscaler-ip-address>/nitro/v1/config/lbvserver?attrs=name,lbmethod

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

  Accept:application/json

- Response:

  HTTP Status Code on Success

200 OK

HTTP Status Code on Failure

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Response Header

Content-Type:application/json

Response Payload

```
{
   lbvserver:
   {
      name: "test",
      lbmethod: "LEASTCONNECTION"
   }
   {
      name: "test1",
      lbmethod: "LEASTCONNECTION"
   }
}
```

Retrieving Statistics of NetScaler Resources

Apr 10, 2015

The NetScaler appliance collects statistics about the usage of its features and the corresponding resources. NITRO can retrieve these statistics.

- To get statistics of a feature, the URL format must be: http://<netscaler-ip-address>/nitro/v1/stat/<feature_name>.
- To get statistics of a resource, the URL format must be: http://<netscaler-ip-address>/nitro/v1/stat/<resource_type>/<resource_name>.
- To get statistics of the services and service groups that are bound to a load balancing virtual server, the URL format must be: http://<netscaler-ip-address>/nitro/v1/stat/lbvserver/<name>?statbindings=yes.

For example, to get the statistics of a load balancing virtual server named MyFirstLbVServer:

- **Request:**

HTTP Method

GET

URL

http://<netscaler-ip-address>/nitro/v1/stat/lbvserver/MyFirstLbVServer

```
Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

Accept:application/json
```

- **Response:**

HTTP Status Code on Success

200 OK

HTTP Status Code on Failure

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

```
{
   "lbvserver":
   [
      {
         "name":"MyFirstLbVServer",
         "establishedconn":0,
         "vslbhealth":0,
         "primaryipaddress":"0.0.0.0",
         ...
      }
   ]
}
```

> **Note**
>
> Not all NetScaler features and resources have statistic objects associated with them.

To get statistics of the bound entities, use statbindings=yes.

For example, to get the statistics of the services that are bound to a load balancing virtual server named MyFirstLbVServer:

- **Request**

HTTP Method

GET

URL

http://<netscaler-ip-address>/nitro/v1/stat/lbvserver/MyFirstLbVServer?statbindings=yes

```
Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

Accept:application/json
```

- Response

HTTP Status code on success
200 OK

HTTP Status code on failure
4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

```
Content-Type:application/json
```

```
{

  "lbvserver": [{

    "name": "MyFirstLbVServer",

    "sortorder": "descending",

    "vsvrsurgecount": "0",

    "establishedconn": "0",

     ...

     ...

    "service": [{
```

```
          "name": "s1",

          "throughput": "0",

          "throughputrate": 0,

           "avgsvrttfb": "0",

            "primaryipaddress": "1.2.3.5",

            "primaryport": 80,

            "servicetype": "HTTP",

            "state": "DOWN",

             "totalrequests": "0",

             "requestsrate": 0,

             ...

             ...

             }]

    }]

}
```

Resetting Properties of a NetScaler Resource

Apr 10, 2015

To unset the value of an attribute of a NetScaler object or reset it to its default value (similar to the "unset" NetScaler CLI commands), specify the action as "unset" in the URL query string, and in the request payload, specify the value of the attributes to be unset as "true" (boolean).

For example, to unset the load balancing method and the comments attributes of a load balancer virtual server named MyFirstLbVServer:

- Request:

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/lbvserver?action=unset

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

  Content-Type:application/json

  Request Payload

```
{
   "lbvserver":
   {
      "name":"MyFirstLbVServer",
      "lbmethod":"true",
      "comment":"true"
   }
}
```

- Response:

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Renaming a NetScaler Resource

Apr 10, 2015

To change the name of an existing resource, specify the action as "rename" in the URL query string, and in the request payload, specify the existing name and the new name.

For example, to change the name of a load balancing virtual server from MyFirstLbVServer to MyServer:

- Request:

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/lbvserver?action=rename

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

  Content-Type:application/json

  Request Payload

```
{
   "lbvserver":
   {
      "name":"MyFirstLbVServer",
      "newname":"MyServer"
   }
}
```

- Response:

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Updating a NetScaler Resource

Apr 10, 2015

To update the details of an existing resource on the NetScaler appliance, specify the name of the resource in the URL, and in the request payload,within the specific resource object, specify the name and the updated details of the resource.

For example, to change the load balancing method to ROUNDROBIN and update the comment property for a load balancing virtual server named MyFirstLbVServer:

- Request:

  HTTP Method

  PUT

  URL

  http://<netscaler-ip-address>/nitro/v1/config/lbvserver/MyFirstLbVServer

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>
  Content-Type:application/json

  Request Payload

```
{
   "lbvserver":
   {
      "name":"MyFirstLbVServer",
      "lbmethod":"ROUNDROBIN",
      "comment":"Updated comments"
   }
}
```

- Response:

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Binding NetScaler Resources

Apr 15, 2015

NetScaler resources form relationships with each other through the process of binding. This is how services are associated with a load balancing virtual server, or how policies are bound to a load balancing virtual server. Each binding relationship is represented by its own object. A binding resource has properties representing the name of each NetScaler resource in the binding relationship. It can also have other properties related to that relationship (for example, the weight of the binding between an lbvserver resource and a service resource).

Read through the following examples to get a better understanding of the bind and unbind operation.

Example 1: To bind a service named "svc_prod" to a load balancing virtual server named "MyFirstLbVServer" and specify a weight for the binding:

- **Request:**

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/lbvserver_service_binding

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>
  Content-Type:application/json

  Request Payload

```
{
   "lbvserver_service_binding":
   {
      "servicename":"svc_prod",
      "weight":"20",
      "name":"MyFirstLbVServer"
   }
}
```

- **Response:**

  HTTP Status Code on Success

  201 Created

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Example 2: To bind a policy to a policy label:

- **Request:**

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/authenticationpolicylabel_authenticationpolicy_binding

Request Headers

Cookie:NITRO_AUTH_TOKEN=<tokenvalue>
Content-Type:application/json

Request Payload

```
{
   "authenticationpolicylabel_authenticationpolicy_binding":
   {
      "policyname":"p1",
      "priority":"100",
      "gotoprioritыexpression":"END",
      "labelname":"pl1"
   }
}
```

- Response:

  HTTP Status Code on Success

  201 Created

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

To unbind a resource, use the DELETE method and specify an "args" query string parameter in the URL that contains the attribute name and value in the relationship resource that designates the secondary resource.

For example, to unbind the service "svc_prod" from the load balancing virtual server "MyFirstLbVServer":

- Request:

  HTTP Method

  DELETE

  URL

  http://<netscaler-ip-address>/nitro/v1/config/lbvserver_service_binding/MyFirstLbVServer?args=servicename:svc_prod

  Request Header

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

- Response:

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Globally Binding NetScaler Resources

Apr 10, 2015

Some NetScaler resources can be bound globally to affect the whole system. For example, if a compression policy is bound to an load balancing virtual server, the policy affects only the traffic on that virtual server. However, if bound globally, it can affect any traffic on the NetScaler appliance regardless of the virtual server that handles the traffic.

The names of NITRO resources that can be used to bind resources globally have the pattern <featurename>global_<resourcetype>_binding. For example, the object aaaglobal_aaapreauthenticationpolicy_binding is used to bind preauthentication policies globally.

For example, to bind the policy named preautpol1 globally at priority 200:

- Request:

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/aaaglobal_aaapreauthenticationpolicy_binding/preautpol1

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>
  Content-Type:application/json

  Request Payload

```
{
  "aaaglobal_aaapreauthenticationpolicy_binding":
  {
    "policy":"preautpol1",
    "priority":"200"
  }
}
```

- Response:

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

To unbind a global resource, in the URL use the args query parameter to specify the resource to be unbound.

For example, to unbind the policy named preautpol1:

- Request:

  HTTP Method

  DELETE

  URL

  http://<netscaler-ip-address>/nitro/v1/config/aaaglobal_aaapreauthenticationpolicy_binding?args=policy:preautpol1

Request Header

Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

- Response:

HTTP Status Code on Success

200 OK

HTTP Status Code on Failure

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Deleting a NetScaler Resource

Nov 16, 2015

The usage of the delete operation depends on the unique identifiers (UIDs) of the resource being deleted.

Deleting Resource with Single UID

To delete a NetScaler resource that can be identified by a single identifier, specify the resource name in the URL.

For example, to delete a load balancing virtual server named MyFirstLbVServer:

- **Request:**

  HTTP Method

  DELETE

  URL

  http://<netscaler-ip-address>/nitro/v1/config/lbvserver/MyFirstLbVServer

  Request Header

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

- **Response:**

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Deleting Resource with Multiple UIDs

To delete a NetScaler resource that is identified using multiple identifiers, use the "args" query parameter to specify the unique attributes along with their values.

For example, consider a SNIP (10.102.29.71) that belongs to two traffic domains (TDs) 123 and 110. To delete the SNIP from one of the traffic domains, specify the IP address and the relevant TD in the URL as follows:

- **Request:**

  HTTP Method

  DELETE

  URL

  http://<netscaler-ip-address>/nitro/v1/config/nsip?args=ipaddress:10.102.29.71,td:123

Request Header

Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

- Response:

HTTP Status Code on Success

200 OK

HTTP Status Code on Failure

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Performing Bulk Operations

Jun 21, 2017

You can create and update multiple resources simultaneously and thus minimize network traffic. For example, you can add/enable/disable multiple load balancing virtual servers in the same operation. To perform a bulk operation, specify the required parameters in the same request payload.

To account for the failure of some operations within the bulk operation, NITRO allows you to configure one of the following behaviors:

- **Exit.** When the first error is encountered, the execution stops. The NITRO operations that were executed before the error are committed. This is the default behavior.
- **Rollback.** When the first error is encountered, the execution stops. The NITRO operations that were executed before the error are rolled back. Rollback is only supported for add and bind NITRO operations.
- **Continue.** All the NITRO operations in the list are executed even if some operations fail.

You must specify the behavior of the bulk operation in the request header using the X-NITRO-ONERROR parameter.

For example, to add two load balancing virtual servers in one operation, and continue even if one of the add operation fails:

- **Request:**

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/lbvserver

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>
  Content-Type:application/json

  Request Payload

```
{
  "lbvserver":
  [
    {
      "name":"new_lbvserver1",
      "servicetype":"http"
    },

    {
      "name":"new_lbvserver2",
      "servicetype":"http"
    }
  ]
}
```

- **Response:**

  HTTP Status Code on Success

  201 Created for the add operation and 200 OK for the update operation.

HTTP Status Code on Failure

207 Multi Status with error details in the response payload. For more information, see Error Handling.

Example for enabling multiple load balancing virtual servers in the same operation

- Request:

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/lbvserver?action=enable

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>
  Content-Type:application/json

  Request Payload

```
{
        "lbvserver":
   [
     {
       "name":"v1",
     },

     {
       "name":"v2",
     }
   ]
}
```

- Response:

  HTTP Status Code on Success

  201 Created for the add operation and 200 OK for the update operation.

  HTTP Status Code on Failure

  207 Multi Status with error details in the response payload. For more information, see Error Handling.

Performing File Operations

Nov 03, 2015

NetScaler operations such as configuring SSL certificates requires the input files to be available locally on the NetScaler appliance. NITRO allows you to perform file operations such as uploading files, retrieving files, retrieving file content, and deleting files of types: txt, cert, req, xml, lic, and key.

Note:

- File size must be less than or equal to 2 MB.
- Use the "BASE64" value for the fileencoding attribute in the request payload. This is the only valid encoding currently supported.
- The filelocation path must be URL encoded. For example, if the path is /nsconfig/ssl, encode the / and use the file location as %2Fnsconfig%2Fssl.
- When uploading a file, make sure that each directory of the file path has the 755 (read, write, execute) permission. For example, to upload a file to the "/nsconfig/ssl/" directory, the following directories must have the 755 permission:
  - flash (because the "/nsconfig" folder is actually a link to "/flash/nsconfig/" directory)
  - nsconfig
  - ssl

Uploading a File

To upload a file to the NetScaler, specify a name for the file, the location where the file must be created on the NetScaler, and the content of the file.

For example, to upload a file named cert1.crt in the /nsconfig/ssl/ directory:

- **Request:**

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/systemfile

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

  Content-Type:application/json

  Request Payload

```
{
   "systemfile":
   {
      "filename": "cert1.crt",
      "filelocation": "/nsconfig/ssl/",
      "filecontent":"VGhpcyBpcyBteSBmaWxl",
      "fileencoding": "BASE64"
   }
}
```

- **Response:**

HTTP Status Code on Success

200 OK

HTTP Status Code on Failure

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Retrieving the Files

To retrieve the files from a specific NetScaler directory, specify the directory path in the URL.

For example, to retrieve the files from the /nsconfig/ssl directory.

- Request:

  HTTP Method

  GET

  URL

  http://<netscaler-ip-address>/nitro/v1/config/systemfile?args=filelocation:%2Fnsconfig%2Fssl

  Request Header

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>
  Accept:application/json

- Response:

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

  Response Header

  Content-Type:application/json

  Response Payload

```
{
   "systemfile":
   [
      {
         "filename": "ns-root.key",
         "filelocation": "/nsconfig/ssl",
         "fileaccesstime": "Tue Jan 14 19:27:01 2014",
         "filemodifiedtime": "Tue Nov  5 17:16:00 2013"
      },
      {
         "filename": "ns-root.req",
         "filelocation": "/nsconfig/ssl",
         "fileaccesstime": "Tue Jan 14 19:27:01 2014",
         "filemodifiedtime": "Tue Nov  5 17:16:00 2013"
      }
```

```
    ]
}
```

Retrieving Contents of a Specific File

To retrieve the contents of a file, specify the filename and its directory path in the URL.

For example, to retrieve the contents of the ns-root.key file from the /nsconfig/ssl directory.

- Request:

  HTTP Method

  GET

  URL

  http://<netscaler-ip-address>/nitro/v1/config/systemfile/ns-root.key?args=filelocation:%2Fnsconfig%2Fssl

  Request Header

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

  Accept:application/json

- Response:

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

  Response Header

  Content-Type:application/json

  Response Payload

```
{
   "systemfile":
   [
      {
         "filename": "ns-root.key",
         "filelocation": "/nsconfig/ssl",
         "filecontent": "LS0tLS1CRUdJTiBSU0EgUFJJVkFU0tLQo=",
         "fileencoding": "BASE64",
         "fileaccesstime": "Tue Jan 14 19:27:01 2014",
         "filemodifiedtime": "Tue Nov  5 17:16:00 2013"
      }
   ]
}
```

Deleting a File

To delete a file from the NetScaler appliance, specify the filename and the directory path in the URL.

For example, to delete the ns-root.key file from the /nsconfig/ssl directory.

- Request:

  HTTP Method

  DELETE

  URL

  https://<netscaler-ip-address>/nitro/v1/config/systemfile/ns-root.key?args=filelocation:%2Fnsconfig%2Fssl

  Request Header

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

- Response:

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Killing a System Session

Apr 10, 2015

A NetScaler administrator can kill any system session by specifying the action as "kill" in the URL query string and by specifying the required system session ID in the request payload.

For example, to kill a system session that has ID as 311:

- Request:

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/systemsession?action=kill

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>
  Content-Type:application/json

  Request Payload

```
{
   "systemsession":
   {
      "sid":"311"
   }
}
```

- Response:

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Disconnecting from the NetScaler Appliance

Apr 10, 2015

Before disconnecting (logging out) from the NetScaler appliance, make sure that you have saved the NetScaler configurations.

To logout of the NetScaler appliance:

- Request:

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/logout

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

  Content-Type:application/json

  Request Payload

  ```
  {
     "logout":{}
  }
  ```

- Response:

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Usage Scenarios

Mar 30, 2015

In this section, we provide NITRO API specific to certain resources and scenarios. We will be adding more scenarios in future updates to this documentation.

Configuring a NetScaler Cluster

Apr 10, 2015

You can use NITRO to add or create and manage a NetScaler cluster.

Cluster Instance Operations

All operations on a cluster instance must be performed on the clusterinstance object.

For example, to create a cluster instance with ID 1, connect to the NetScaler appliance that you are first adding to the cluster:

- **Request:**

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/clusterinstance

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

  Content-Type:application/json

  Request Payload

```
{
   "clusterinstance":
   {
      "clid":1,
      "preemption":"ENABLED"
   }
}
```

- **Response:**

  HTTP Status Code on Success

  201 Created

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Cluster Node Operations

All operations on a cluster node must be performed on the clusternode object.

For example, to add a NetScaler appliance with NSIP address 10.102.29.60 to the cluster:

- **Request:**

  HTTP Method

  POST

  URL

http://<netscaler-ip-address>/nitro/v1/config/clusternode

Request Headers

Cookie:NITRO_AUTH_TOKEN=<tokenvalue>
Content-Type:application/json

Request Payload

```
{
   "clusternode":
   {
      "nodeid":1,
      "ipaddress":"10.102.29.60",
      "state":"ACTIVE",
      "backplane":"1/1/2"
   }
}
```

- **Response:**

  HTTP Status Code on Success

  201 Created

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Add a Cluster IP Address

To define a cluster IP address, specify the required parameters in the nsip object.

For example, to configure a cluster IP address:

- **Request:**

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/nsip

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>
  Content-Type:application/json

  Request Payload

```
{
   "nsip":
   {
      "ipaddress":"10.102.29.61",
      "netmask":"255.255.255.255",
      "type":"CLIP"
   }
}
```

- **Response:**

  HTTP Status Code on Success

  201 Created

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Add a Spotted IP Address

To configure an IP address as spotted, specify the required parameters in the nsip object. This configuration must be done on the cluster IP address.

For example, to configure a spotted SNIP address on a node with ID 1:

- **Request:**

  HTTP Method

  POST

  URL

  http://<cluster-ip-address>/nitro/v1/config/nsip

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>
  Content-Type:application/json

  Request Payload

```
{
   "nsip":
   {
      "ipaddress":"10.102.29.77",
      "netmask":"255.255.255.0",
      "type":"SNIP",
      "ownernode":1
   }
}
```

- **Response:**

  HTTP Status Code on Success

  201 Created

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Join NetScaler Appliance to Cluster

To join an appliance to a cluster, specify the required parameters in the cluster object.

For example, to join a NetScaler appliance to a cluster:

- **Request:**

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/cluster

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>
  Content-Type:application/json

  Request Payload

```
{
   "cluster":
   {
      "clip":"10.102.29.61",
      "password":"verysecret"
   }
}
```

- **Response:**

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Linkset Operations

To configure a linkset, do the following:

1. Create a linkset by specifying the required parameters in the linkset object.
   For example, to add a linkset LS/1:
   - **Request:**

     HTTP Method

     POST

     URL

     http://<cluster-ip-address>/nitro/v1/config/linkset

     Request Headers

     Cookie:NITRO_AUTH_TOKEN=<tokenvalue>
     Content-Type:application/json

     Request Payload

```
{
   "linkset":
   {
      "id":"LS/1"
   }
```

```
}
```

- **Response:**

  HTTP Status Code on Success

  201 Created

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

2. Bind the required interfaces to the linkset by specifying the interfaces in the linkset_interface_binding object.
   For example, to bind interfaces 1/1/2 and 2/1/2 to linkset LS/1:

- **Request:**

  HTTP Method

  PUT

  URL

  http://<cluster-ip-address>/nitro/v1/config/linkset_interface_binding/LS%2F1?action=bind
  Note: The linkset name (LS/1), must be URL encoded as LS%2F1.

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>
  Content-Type:application/json

  Request Payload

```
{
   "linkset_interface_binding":
   {
      "id":"LS/1",
      "ifnum":"1/1/2 2/1/2"
   }
}
```

- **Response:**

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Configuring Admin Partitions

Apr 10, 2015

To create an admin partition, you must perform a set of operations on the default partition. To understand this procedure, let us consider a company that has two departments each of which has an application that requires the NetScaler functionality. The NetScaler admin wants to have a different partition for each department so that there is isolation of users and configurations. The NetScaler admin must do the following (the sample shows configurations only for a single admin partition):

Note: For detailed information and best practices, see Admin Partitions.

1. Create a partition and allocate the required resources to that partition.

- **Request:**

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/nspartition

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

  Content-Type:application/json

  Request Payload

```
{
   "nspartition":
   {
      "partitionname":"partition-dept1",
      "maxbandwidth":"10240",
      "minbandwidth":"10240",
      "maxconn":"1024",
      "maxmemlimit":"10"
   }
}
```

- **Response:**

  HTTP Status Code on Success

  201 Created

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

2. Associate the appropriate users with the partition.

- **Request:**

  HTTP Method

  PUT

  URL

http://<netscaler-ip-address>/nitro/v1/config/systemuser_nspartition_binding/user1

Request Headers

Cookie:NITRO_AUTH_TOKEN=<tokenvalue>
Content-Type:application/json

Request Payload

```
{
   "systemuser_nspartition_binding":
   {
      "username":"user1",
      "partitionname":"partition-dept1"
   }
}
```

- **Response:**

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

3. Associate an appropriate command policy to the admin partition user.
   - **Request:**

     HTTP Method

     PUT

     URL

     http://<netscaler-ip-address>/nitro/v1/config/systemuser_systemcmdpolicy_binding/user1

     Request Headers

     Cookie:NITRO_AUTH_TOKEN=<tokenvalue>
     Content-Type:application/json

     Request Payload

```
{
   "systemuser_systemcmdpolicy_binding":
   {
      "username":"user1",
      "policyname":"partition-admin",
      "priority":"1"
   }
}
```

   - **Response:**

     HTTP Status Code on Success

     200 OK

     HTTP Status Code on Failure

     4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides

details of the error.

4. Specify the VLANs or bridgegroups to be associated with the partition. This step ensures network isolation of the traffic. Traffic received on the interfaces of the VLAN or bridgegroup is isolated from the traffic of other partitions.
   - **Request:**

     HTTP Method

     PUT

     URL

     http://<netscaler-ip-address>/nitro/v1/config/nspartition_vlan_binding/partition-dept1

     Request Headers

     Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

     Content-Type:application/json

     Request Payload

     ```
     {
       "nspartition_vlan_binding":
       {
         "partitionname":"partition-dept1",
         "vlan":"2"
       }
     }
     ```

   - **Response:**

     HTTP Status Code on Success

     200 OK

     HTTP Status Code on Failure

     4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

5. Save the configurations.
   - **Request:**

     HTTP Method

     POST

     URL

     http://<netscaler-ip-address>/nitro/v1/config/nsconfig?action=save

     Request Headers

     Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

     Content-Type:application/json

     Request Payload

     ```
     {
       "nsconfig":
       {
       }
     }
     ```

- **Response:**

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

  The admin partition is created.

6. Now, to configure this admin partition, you must log out of the default partition and log on again. You are automatically taken to the admin partition to which you were first bound and once there you can configure the NetScaler.
   Note: If you want to configure another admin partition, perform the switch operation given in the next step before performing this step.
7. [Optional] If you are associated with multiple admin partitions, you can switch to the required partition.
   - **Request:**

     HTTP Method

     POST

     URL

     http://<netscaler-ip-address>/nitro/v1/config/nspartition?action=Switch

     Request Headers

     Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

     Content-Type:application/json

     Request Payload

     ```
     {
       "nspartition":
       {
         "partitionname":"partition-dept2"
       }
     }
     ```

   - **Response:**

     HTTP Status Code on Success

     200 OK

     HTTP Status Code on Failure

     4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

8. View the partitions that are available on the NetScaler appliance. If a user is associated with more than one partition, the response payload includes the "partitiontype" attribute the value of which indicates the partition to which the user is currently logged on.
   - **Request:**

     HTTP Method

     GET

     URL

http://<netscaler-ip-address>/nitro/v1/config/nspartition

Request Headers

Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

Accept:application/json

- **Response:**

HTTP Status Code on Success

200 OK

HTTP Status Code on Failure

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Response Header

Content-Type:application/json

Response Payload

```
{
   "nspartition":
   {
      "partitionname":"partition-dept1",
      "partitionid": "2",
      "partitiontype": "Current Partition",
      "maxbandwidth":"10240",
      "minbandwidth":"10240",
      "maxconn":"1024",
      "maxmemlimit":"10"
   }
}
```

Managing AppExpert Applications

Apr 10, 2015

To export an AppExpert application, specify the parameters needed for the export operation in the apptemplateinfo object. Optionally, you can specify basic information about the AppExpert application template, such as the author of the configuration, a summary of the template functionality, and the template version number, in the template_info object. This information is stored as part of the template file that is created.

For example, to export an AppExpert application named MyApp1:

- **Request:**

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/apptemplateinfo?action=export

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

  Content-Type:application/json

  Request Payload

```
{
   "apptemplateinfo":
   {
      "appname":"MyApp1",
      "apptemplatefilename":"BizAp.xml",
      "template_info":
      {
         "templateversion_major":"2",
         "templateversion_minor":"1",
         "author":"XYZ",
         "introduction":"Intro",
         "summary":"Summary"
      }
   }
}
```

- **Response:**

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

To import an AppExpert application, specify the parameters needed for the import operation in the apptemplateinfo object.

For example, to import an AppExpert application named MyApp1:

- **Request:**

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/apptemplateinfo?action=import

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

  Content-Type:application/json

  Request Payload

```
{
  "apptemplateinfo":
  {
     "apptemplatefilename":"BizAp.xml",
     "deploymentfilename":"BizAp_deployment.xml",
     "appname":"MyApp1"
  }
}
```

- **Response:**

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

To import an AppExpert application by specifying different deployment settings:

- **Request:**

  HTTP Method

  POST

  URL

  http://<netscaler-ip-address>/nitro/v1/config/apptemplateinfo?action=import

  Request Headers

  Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

  Content-Type:application/json

  Request Payload

```
{
  "apptemplateinfo":
  {
     "apptemplatefilename":"BizAp.xml",
     "appname":"Myapp2",
      "deploymentinfo":
      {
         "appendpoint":
         [
```

```
            {
               "ipv46":"11.2.3.8",
               "port":80,
               "servicetype":"HTTP"
            }
         ],
         "service":
         [
            {
               "ip":"12.3.3.15",
               "port":80,
               "servicetype":"SSL"
            },
            {
               "ip":"14.5.5.16",
               "port":443,
               "servicetype":"SSL"
            }
         ]
      }
   }
}
```

- **Response:**

  HTTP Status Code on Success

  200 OK

  HTTP Status Code on Failure

  4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Automate NetScaler Upgrade and Downgrade with a Single API

Jun 08, 2016

You can use the "install" API to automate not just installation, but also an upgrade or a downgrade of the build on a NetScaler appliance. You can specify a local or remote location for the build file.

For example, the following information describes a downgrade to NetScaler release 10.5 build 46, using a local build file:

- Request

HTTP Method

POST

URL

http://<NSIP>/nitro/v1/config/install

Request Headers COPY

```
Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

Content-Type: application/json
```

Code COPY

```

```

Request Payload COPY

```
{
  “install”:
    {
      “url”: “file:///var/tagma/build_tagma_46_nc.tgz”
    }
}
```

- Response

HTTP status Code on Success
201 Created

209 Netscaler specific warning

Note: when “y” option is not specified and warning is enabled, API returns “1120 - The configuration must be saved and the system rebooted for these settings to take effect” message in X-NITRO-WARNING.

HTTP Status Code on Failure
599 Netscaler specific error

Additional parameters available in the install API request payload:

“y”:“true” - This option enables reboot on successful loading of kernel.

“L”:“true” - This option enables the callhome feature.

Supported formats for the "url" parameter (specifies the location of the tar.gz file for the build):

- http://[user]:[password]@host/path/to/file
- https://[user]:[password]@host/path/to/file
- sftp://[user]:[password]@host/path/to/file
- scp://[user]:[password]@host/path/to/file
- ftp://[user]:[password]@host/path/to/file
- file://path/to/file

Possible errors:

- Installation failed. [No space on file system. Please check the log file /var/tmp/install]
- Installation failed. [File transfer failed]
- Installation failed. [File does not exist]
- Installation failed. [Failed to copy file to /var/tmp]
- Installation failed. [Extraction failed, invalid tar archive?]

- Installation failed. [Invalid file transfer protocol]
- Installation failed. [Unable to create temporary directory]
- Installation failed. [Please check the log file /var/tmp/install for more information]

Handle Multiple NITRO Calls in a Single Request

Jun 08, 2016

You can use the "macroapi" API to create, update, and delete multiple resources simultaneously, and thereby minimize network traffic. For example, multiple load-balancing virtual servers can be added in a single API.

To account for the failure of some operations within the bulk operation, NITRO allows configuring one of the following behaviors.

- EXIT: When the first error is encountered, execution stops. The commands that were executed before the error are committed.
- ROLLBACK: When the first error is encountered, execution stops. The commands that were executed before the error are rolled back. Rollback is supported for add and bind commands only.
- CONTINUE: All the commands in the request are executed even if some commands fail.

You must specify the behavior of the bulk operation in the request header, by using the X-NITRO-ONERROR parameter.

Advantages

- Heterogeneous resources can be configured with a single API. For example, multiple load balancing virtual servers and multiple services can be created, and services can be bound to load balancing virtual servers in a single API.

Limitations

- Only homogenous operation is supported in this API. For example, multiple load balancing virtual servers can be created but cannot be updated or deleted in the same API.
- “rollback” is supported only on “add” and “bind” operations.

For example, to add multiple load balancing resources in a single request:

HTTP Method

POST

URL

http://<NSIP>/nitro/v1/config/macroapi

Request Headers COPY

```
Content-Type: application/json

Cookie: NITRO_AUTH_TOKEN=<tokenvalue>

X-NITRO-ONERROR: exit
```

Request Payload COPY

```
{
 "lbvserver":[
                    {"name":"lbv1","servicetype":"http"},
                    {"name":"lbv2","servicetype":"http"}
          ],
 "serviceGroup": [
                  { "servicegroupname": "sg1", "servicetype": "HTTP" },
                    { "servicegroupname": "sg2", "servicetype": "HTTP" }
  ],
 "lbvserver_servicegroup_binding":[
                  { "name":"lbv1", "servicegroupname":"sg1" },
                   { "name":"lbv2", "servicegroupname":"sg2" }
  ]
}
```

- Response:

HTTP Status Code on Success

201 Created for the add operation and 200 OK for the update operation.

HTTP Status Code on Failure

207 Multi Status with error details in the response payload. For more information, see Error Handling.

For deleting multiple resources using macroapi, use POST HTTP method with query parameter “action=remove” in the URI.

Simplify Management Operations with an idempotent API

Jun 08, 2016

You can add or update NetScaler resources seamlessly, with a single API. Previously, an attempt to add a resource that was already configured, or to update a resource that was not yet configured, caused an error.

If you enable the “idempotent” query parameter (“idempotent=yes”) in any POST request, NITRO executes the request in an idempotent manner. An idempotent HTTP method is an HTTP method that can be called many times without different results, and POST is desinged as a non-idempotent method.

> **Note**
>
> Use POST request with “idempotent” option if you are unsure whether the resource in the request exists on NetScaler or not.

This API hides the inconsistencies between parameter lists of POST and PUT operations. For some NITRO resources, certain parameters are accepted only on PUT not in POST, or vice versa. By using this idempotent API, you can overcome such challenges.

Limitations

- If a resource is already configured and you try to add the same resource again, the resource is "updated," but the arguments already present are not unset. For example, if a load balancing virtual server named "V1" is configured to use the round robin load balancing method, and you try to ADD an lbvserver named "V1" without specifying a value for "lbmethod" in the request, the NetScaler appliance does not unset "lbmethod" to its default value of "leastconnection."

In the following example, “preferredntpserver” is allowed only in PUT, but when given in POST request with idempotent=yes, NITRO internally adds the ntpserver and updates it with given properties.

HTTP Method

POST

URL

http://<NSIP>/nitro/v1/config/ntpserver?idempotent=yes

Request Headers COPY

```
Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

Content-Type: application/json
```

Request Payload COPY

```
{

        “ntpserver”:{“servername”:“ntp1”,“minpoll”:“4”,“preferredntpserver”: “yes”}

}
```

- Response

HTTP Status Code on Success
200 OK

HTTP Status Code on Failure
4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Retrieve Bindings in Bulk

Jun 08, 2016

You can use a bulk GET API to fetch bindings of all the entities of a given entity type.

For example, you can fetch bindings of all the load balancing virtual servers in one call instead of by using multiple GET by "name" calls. In the examples below, the NetScaler appliance has the following configuration.

- add lb vserver lbv1 http
- add lb vserver lbv2 http
- add service svc1 10.20.30.40 http 80
- add servicegroup sg1 http
- bind lb vserver lbv1 svc1
- bind lb vserver lbv1 sg1
- bind lb vserver lbv2 svc1
- bind lb vserver lbv2 sg1

Example. To fetch bindings of all lbvservers, in a single NITRO API:

- Request

HTTP Method
GET

URL
http://<NSIP>/nitro/v1/config/lbvserver_binding?bulkbindings=yes

Request Headers COPY

```
Cookie:NITRO_AUTH_TOKEN=<tokenvalue>

Accept: application/json
```

- Response

HTTP Status Code on Success
200 OK

HTTP Status Code on Failure
4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors). The response payload provides details of the error.

Response Header COPY

```
Content-Type:application/json
```

Response Payload COPY

```
{
   "errorcode":0,
   "message":"Done",
   "severity":"NONE",
   "lbvserver_binding":[
      {
         "name":"lbv1",
         "lbvserver_service_binding":[
            {
               "name":"lbv1",
               "servicename":"svc1",
               "stateflag":"536936451",
               "ipv46":"10.20.30.40",
               "port":80,
               "servicetype":"HTTP",
               "curstate":"DOWN",
               "weight":"1",
               "dynamicweight":"0",
               "cookieipport":"",
               "vserverid":"mcw1",
               "vsvrbindsvcip":"10.20.30.40",
               "vsvrbindsvcport":80,
```

```
        "preferredlocation":""
      }
    ],
    "lbvserver_servicegroup_binding":[
      {
        "name":"lbv1",
        "servicegroupname":"sg1",
        "stateflag":"536936464",
        "servicename":"sg1"
      }
    ]
  },
  {
    "name":"lbv2",
    "lbvserver_service_binding":[
      {
        "name":"lbv2",
        "servicename":"svc1",
        "stateflag":"536936451",
        "ipv46":"10.20.30.40",
        "port":80,
        "servicetype":"HTTP",
        "curstate":"DOWN",
        "weight":"1",
        "dynamicweight":"0",
        "cookieipport":"",
        "vserverid":"mcw2"
```

```
            "vsvrbindsvcip":"10.20.30.40",
            "vsvrbindsvcport":80,
            "preferredlocation":""
          }
        ],
      "lbvserver_servicegroup_binding":[
          {
            "name":"lbv2",
            "servicegroupname":"sg1",
            "stateflag":"536936464",
            "servicename":"sg1"
          }
        ]
    }
  ]
}
```

Example. To fetch only “service” bindings of all lbvservers:

- Request

HTTP Method

GET

URL

http://<NSIP>/nitro/v1/config/lbvserver_service_binding?bulkbindings=yes

Request Header COPY

```
Content-Type:application/json
```

Response Payload COPY

```
{
   "errorcode":0,
   "message":"Done",
   "severity":"NONE",
   "lbvserver_service_binding":[
      {
         "name":"lbv1",
         "servicename":"svc1",
         "stateflag":"536936451",
         "ipv46":"10.20.30.40",
         "port":80,
         "servicetype":"HTTP",
         "curstate":"DOWN",
         "weight":"1",
         "dynamicweight":"0",
         "cookieipport":"",
         "vserverid":"mcw1",
         "vsvrbindsvcip":"10.20.30.40",
         "vsvrbindsvcport":80,
         "preferredlocation":""
      },
      {
```

```
        "name":"lbv2",
        "servicename":"svc1",
        "stateflag":"536936451",
        "ipv46":"10.20.30.40",
        "port":80,
        "servicetype":"HTTP",
        "curstate":"DOWN",
        "weight":"1",
        "dynamicweight":"0",
        "cookieipport":"",
        "vserverid":"mcw2",
        "vsvrbindsvcip":"10.20.30.40",
        "vsvrbindsvcport":80,
        "preferredlocation":""
      }
  ]
}
```

Error Handling

Feb 13, 2017

In case of a failed request, NITRO provides the required information through the HTTP status code and in the response header and response payload.

- Error in a Single Resource Operation
- Error in a Bulk Operations
- Warnings in NITRO Opetations

Error in a Single Resource Operation

The response of a single erroneous operation is as follows:

HTTP Status Code

4xx <string> (for general HTTP errors) or 5xx <string> (for NetScaler-specific errors)

Response Header

Content-Type:application/json

Response Payload

```
{
   errorcode: <Error code>,
   message: "<Error message>",
   severity: "ERROR"
}
```

Error in a Bulk Operation

When there is a failure in one of the bulk operations, the response payload gives a combination of success and failure (depends on the value set for X-NITRO-ONERROR in the request header).

HTTP Status Code

207 Multi Status

Response Header

Content-Type:application/json

Response Payload when X-NITRO-ONERROR is set to continue

When the first operation fails, the request is not terminated. The response payload shows the error details of the failed operation and the success status of the other operations.

```
{
   "errorcode": 1243,
   "message": "Bulk operation failed",
   "severity": "ERROR",
   "response":
   [
      {
         "errorcode": 273,
         "message": "Resource already exists",
         "severity": "ERROR"
```

```
    },
    {
      "errorcode": 0,
      "message": "Done",
      "severity": "NONE"
    }
  ]
}
```

Response Payload when X-NITRO-ONERROR is set to exit

When the first operation fails, the request is terminated. The response payload only shows the error details of the failed operation.

```
{
  "errorcode": 1243,
  "message": "Bulk operation failed",
  "severity": "ERROR",
  "response":
  [
    {
      "errorcode": 273,
      "message": "Resource already exists",
      "severity": "ERROR"
    }
  ]
}
```

Warnings in NITRO Operations

Warnings can be captured by specifying the "warning" query parameter as "yes" when performing any NITRO operation. For example, to get warnings while connecting to the NetScaler appliance, the URL is as follows:

http://<netscaler-ip-address>/nitro/v1/config/lbvserver?warning=yes

If there are any warnings, the response is as follows:

HTTP Status Code

209 X-NITRO-WARNING

Response Header

X-NITRO-WARNING →1067 - Feature(s) not enabled [LB]

API Reference

Jul 05, 2017

- Error Messages

Java, .NET, and Python API

Oct 14, 2015

This section provides basic information for using the Java, .NET, and Python SDKs that are provided for the NITRO API. The API are categorized on their scope and purpose.

Important

- All NITRO operations are logged in the /var/log/nitro.log file on the appliance.

- Executable samples are available in the *<NITRO_SDK_HOME>/sample* directory.

Tutorial: Create Your First NITRO Application

Sep 12, 2012

After completing this tutorial, you will understand and be able to use NITRO to log in to the appliance, create a load balancing virtual server, retrieve details of an lbvserver, delete an lbvserver, save the configurations on the appliance, and log out of the appliance.

- Using Java API to Create your First NITRO Application
- Using .NET API to Create your First NITRO Application

> **Note**
>
> Before you begin, make sure that you have the latest NITRO SDK and that the client application satisfies the prerequisites for using the NITRO SDK.
>
> All NITRO exceptions are captured by the *com.citrix.netscaler.nitro.exception.nitro_exception* class. For a more detailed description, see Exception Handling.
>
> The executable code for the sample is available in the <NITRO_SDK_HOME>/sample/ directory.

Using Java API to Create your First NITRO Application

1. Copy the libraries from <NITRO_SDK_HOME>/lib folder to the project classpath.
2. Create a new class and name it **MyFirstNitroApplication**.
3. Create an instance of com.citrix.netscaler.nitro.service.nitro_service class. This instance is used to perform all operations on the appliance:
   ```
   nitro_service ns_session = new nitro_service("10.102.29.170","HTTP");
   ```
   This code establishes a connection with an appliance that has IP address 10.102.29.170 and uses the HTTP protocol. Replace 10.102.29.170 with the IP address of the NetScaler appliance that you have access to.
4. Use the nitro_service instance to log in to the appliance using your credentials:
   ```
   ns_session.login("admin","verysecret");
   ```
   This code logs into the appliance, with user name as admin and password as verysecret. Replace the credentials with your login credentials.
5. Enable the load balancing feature:
   ```
   String[] features_to_be_enabled = {"lb"};
   ns_session.enable_features(features_to_be_enabled);
   ```
   This code first sets the features to be enabled in an array and then enables the LB feature.
6. Create an instance of the com.citrix.netscaler.nitro.resource.config.lb.lbvserver class. You will use this instance to perform operations on the lbvserver.
   ```
   lbvserver new_lbvserver_obj = new lbvserver();
   ```
7. Use the lbvserver instance to create a new lbvserver:
   ```
   new_lbvserver_obj.set_name("MyFirstLbVServer");
   new_lbvserver_obj.set_ipv46("10.102.29.88");
   new_lbvserver_obj.set_servicetype("HTTP");
   new_lbvserver_obj.set_port(88);
   new_lbvserver_obj.set_lbmethod("ROUNDROBIN");
   ```

lbvserver.add(ns_session,new_lbvserver_obj);
This code first sets the attributes (name, IP address, service type, port, and load balancing method) of the lbvserver locally and then adds it to the appliance by using the corresponding add() method.

8. Retrieve the details of the lbvserver you have created:
   new_lbvserver_obj = lbvserver.get(ns_session,new_lbvserver_obj.get_name());
   System.out.println("Name : " +new_lbvserver_obj.get_name() +"\n" +"Protocol : " +new_lbvserver_obj.get_servicetype());
   This code first retrieves the details of the lbvserver as an object from the NetScaler, extracts the required attributes (name and service type) from the object, and displays the results.
9. Delete the lbvserver you created in the above steps:
   lbvserver.delete(ns_session, new_lbvserver_obj.get_name());
10. Save the configurations:
    ns_session.save_config();
11. Log out of the appliance:
    ns_session.logout();

Using .NET API to Create your First NITRO Application

1. Copy the libraries from <NITRO_SDK_HOME>/lib folder to the project classpath.
2. Create a new class and name it **MyFirstNitroApplication**.
3. Create an instance of com.citrix.netscaler.nitro.service.nitro_service class. This instance is used to perform all operations on the appliance:
   nitro_service ns_session = new nitro_service("10.102.29.170", "http");
   This code establishes a connection with an appliance that has IP address 10.102.29.170 and uses the HTTP protocol. Replace 10.102.29.170 with the IP address of the NetScaler appliance that you have access to.
4. Use the nitro_service instance to log in to the appliance using your credentials:
   ns_session.login("admin","verysecret");
   This code logs into the appliance, with user name as admin and password as verysecret. Replace the credentials with your login credentials.
5. Enable the load balancing feature:
   String[] features_to_be_enabled = {"lb"};
   ns_session.enable_features(features_to_be_enabled);
   This code enables load balancing on the appliance.
6. Create an instance of the com.citrix.netscaler.nitro.resource.config.lb.lbvserver class. You will use this instance to perform operations on the lbvserver.
   lbvserver new_lbvserver_obj = new lbvserver();
7. Use the lbvserver instance to create a new lbvserver:
   new_lbvserver_obj.name = "MyFirstLbVServer";
   new_lbvserver_obj.ipv46 = "10.102.29.88";
   new_lbvserver_obj.servicetype = "HTTP";
   new_lbvserver_obj.port = 80;
   new_lbvserver_obj.lbmethod = "ROUNDROBIN";
   lbvserver.add(ns_session,new_lbvserver_obj);
   This code first sets the attributes (name, IP address, service type, port, and load balancing method) of the lbvserver locally and then adds it to the appliance by using the corresponding add() method.
8. Retrieve the details of the lbvserver you have created:
   lbvserver new_lbvserver_obj1 = lbvserver.get(ns_session,new_lbvserver_obj.name);
   System.Console.Out.WriteLine("Name : " +new_lbvserver_obj1.name +"\n" +"Protocol : " +new_lbvserver_obj1.servicetype);
   This code first retrieves the details of the lbvserver as an object from the NetScaler, extracts the required attributes

(name and service type) from the object, and displays the results.

9. Delete the lbvserver you created in the above steps:
   lbvserver.delete(ns_session, new_lbvserver_obj.name);
10. Save the configurations:
    ns_session.save_config();
11. Log out of the appliance:
    ns_session.logout();

Tutorial: Create a NetScaler Cluster

Nov 05, 2013

This tutorial gives you the step-by-step process to create a NetScaler cluster. After completing this tutorial you will be able to create a two-node NetScaler cluster. To add more appliances to the cluster you must repeat the procedure that adds and joins the node to the cluster.

- Using Java API to Create a Cluster
- Using .NET API to Create a Cluster

> **Note**
>
> The executable code for the sample is available in the *<NITRO_SDK_HOME>/sample/* directory.

Using Java API to Create a Cluster

1. Copy the libraries from <NITRO_SDK_HOME>/lib folder to the project classpath.
2. Create a new class and name it CreateCluster.
3. Log on to one of the appliances that you want to add to the cluster and create a cluster:

```
//Connect to the first appliance that you want to add to the cluster
nitro_service nonClipSession0 = new nitro_service(nsipAddress0,protocol);
nonClipSession0.login(uName,password);

//Create a cluster instance
clusterinstance newClusterInstance = new clusterinstance();
newClusterInstance.set_clid(1);
clusterinstance.add(nonClipSession0,newClusterInstance);

//Add the appliance to the cluster
clusternode ClusterNode0 = new clusternode();
ClusterNode0.set_nodeid(0);
ClusterNode0.set_ipaddress(nsipAddress0);
ClusterNode0.set_state("ACTIVE");
ClusterNode0.set_backplane("0/1/1");
clusternode.add(nonClipSession0,ClusterNode0);

//Add the cluster IP address
nsip newNSIPAddress = new nsip();
newNSIPAddress.set_ipaddress(clipAddress);
newNSIPAddress.set_netmask("255.255.255.255");
newNSIPAddress.set_type("CLIP");
nsip.add(nonClipSession0,newNSIPAddress);

//Enable the cluster instance
clusterinstance.enable(nonClipSession0, newClusterInstance);

//Save the configurations
nonClipSession0.save_config();

//Warm reboot the appliance
nonClipSession0.reboot(true);
```

The cluster is created and the first node is added to the cluster. This node becomes the initial configuration coordinator of the cluster.

4. Log on to the cluster IP address to add other appliances to the cluster:

```
//Connect to the cluster IP address
nitro_service clipSession = new nitro_service(clipAddress,protocol);
clipSession.login(uName,password);

//Add the node to the cluster
clusternode ClusterNode1 = new clusternode();
ClusterNode1.set_nodeid(1);
ClusterNode1.set_ipaddress(nsipAddress1);
ClusterNode1.set_state("ACTIVE");
ClusterNode1.set_backplane("1/1/1");
clusternode.add(clipSession,ClusterNode1);

//Save the configurations
clipSession.save_config();
```

5. Log on to the appliance that you added in the previous step and join it to the cluster:

```
//Connect to the node that you have just added to the cluster
nitro_service nonClipSession1 = new nitro_service(nsipAddress1,protocol);
nonClipSession1.login(uName,password);

//Join the node to the cluster
cluster newCluster = new cluster();
newCluster.set_clip(clipAddress);
newCluster.set_password(password);
cluster.join(nonClipSession1,newCluster);

//Save the configurations
nonClipSession1.save_config();

//Warm reboot the appliance
nonClipSession1.reboot(true);
```

The second node is now a part of the cluster.

6. Verify the details of the cluster by logging on to the cluster IP address

```
//Retrieving the cluster node details
Long id = new Long(1);
clusternode node= clusternode.get(clipSession, id);
System.out.println("Node ID: "+ node.get_nodeid() + " | Admin state: " + node.get_state() + " | Backplane interface: "+ node.get_backplane());

//Retrieving the cluster instance details
Long id1 = new Long(1);
clusterinstance instance= clusterinstance.get(clipSession, id1);
System.out.println("Cluster instance ID: "+ instance.get_clid() + " | Operational state: " +instance.get_operationalstate());
```

Using .NET API to Create a Cluster

1. Copy the libraries from <NITRO_SDK_HOME>/lib folder to the project classpath.
2. Create a new class and name it CreateCluster.
3. Log on to one of the appliances that you want to add to the cluster and create a cluster:

```
//Connect to the first appliance that you want to add to the cluster
nitro_service nonClipSession0 = new nitro_service(nsipAddress0,protocol);
nonClipSession0.login(uName,password);

//Create a cluster instance
```

```
clusterinstance newClusterInstance = new clusterinstance();
newClusterInstance.clid = 1;
clusterinstance.add(nonClipSession0,newClusterInstance);

//Add the appliance to the cluster
clusternode ClusterNode0 = new clusternode();
ClusterNode0.nodeid = 0;
ClusterNode0.ipaddress = nsipAddress0;
ClusterNode0.state = "ACTIVE";
ClusterNode0.backplane = "0/1/1";
clusternode.add(nonClipSession0,ClusterNode0);

//Add the cluster IP address
nsip newNSIPAddress = new nsip();
newNSIPAddress.ipaddress = clipAddress;
newNSIPAddress.netmask = "255.255.255.255";
newNSIPAddress.type = "CLIP";
nsip.add(nonClipSession0,newNSIPAddress);

//Enable the cluster instance
clusterinstance.enable(nonClipSession0, newClusterInstance);

//Save the configurations
nonClipSession0.save_config();

//Warm reboot the appliance
nonClipSession0.reboot(true);
```

The cluster is created and the first node is added to the cluster. This node becomes the initial configuration coordinator of the cluster.

4. Log on to the cluster IP address to add other appliances to the cluster:

```
//Connect to the cluster IP address
nitro_service clipSession = new nitro_service(clipAddress,protocol);
clipSession.login(uName,password);

//Add the node to the cluster
clusternode ClusterNode1 = new clusternode();
ClusterNode1.nodeid = 1;
ClusterNode1.ipaddress = nsipAddress1;
ClusterNode1.state = "ACTIVE";
ClusterNode1.backplane = "1/1/1";
clusternode.add(clipSession,ClusterNode1);

//Save the configurations
clipSession.save_config();
```

5. Log on to the appliance that you added in the previous step and join it to the cluster:

```
//Connect to the node that you have just added to the cluster
nitro_service nonClipSession1 = new nitro_service(nsipAddress1,protocol);
nonClipSession1.login(uName,password);

//Join the node to the cluster
cluster newCluster = new cluster();
newCluster.clip = clipAddress;
newCluster.password = password;
```

```
cluster.join(nonClipSession1,newCluster);

//Save the configurations
nonClipSession1.save_config();

//Warm reboot the appliance
nonClipSession1.reboot(true);
```

The second node is now a part of the cluster.

6. Verify the details of the cluster by logging on to the cluster IP address

```
//Retrieving the cluster node details
uint id = 1;
clusternode node= clusternode.get(clipSession, id);
System.Console.Out.WriteLine("Node ID: " + node.nodeid + " | Admin state: " + node.state + " | Backplane interface: " + node.backplane);

//Retrieving the cluster instance details
uint id1 = 1;
clusterinstance instance= clusterinstance.get(clipSession, id1);
System.Console.Out.WriteLine("Cluster instance ID: "+ instance.clid + " | Operational state: " +instance.operationalstate);
```

Connecting to the NetScaler Appliance

Oct 16, 2015

The first step towards using NITRO is to establish a session with the NetScaler appliance and then authenticate the session by using the NetScaler administrator's credentials.

You must create an object of the *com.citrix.netscaler.nitro.service.nitro_service* class by specifying the NetScaler IP (NSIP) address and the protocol to connect to the appliance (HTTP or HTTPS). You then use this object and log on to the appliance by specifying the user name and the password of the NetScaler administrator.

Note:

- For the python SDK, the package path is of the form *nssrc.com.citrix.netscaler...*
- You must have a user account on that appliance. The configuration operations that you perform are limited by the administrative roles assigned to your account.

The following sample code establishes a session with a NetScaler appliance with IP address 10.102.29.60 by using the HTTPS protocol and also sets a session timeout period (in seconds) of 60 minutes.

Java - Sample code to establish session COPY

```
//Specify the NetScaler appliance IP address and protocol

nitro_service ns_session = new nitro_service("10.102.29.60","https");

//Specify the login credentials

ns_session.login("admin","verysecret",3600);
```

.NET - Sample code to establish session COPY

```
//Specify the NetScaler appliance IP address and protocol

nitro_service ns_session = new nitro_service("10.102.29.60","https");

//Specify the login credentials

ns_session.login("admin","verysecret",3600);
```

Python - Sample code to establish session

```
#Specify the NetScaler appliance IP address and protocol

ns_session = nitro_service("10.102.29.60","https")

#Specify the login credentials

ns_session.login("admin","verysecret",3600)
```

Disable SSL Checks

When using HTTPS, you must make sure that the root CA is added to the truststore. By default, NITRO validates the SSL certificate and verifies the hostname. Disable these validations as shown in the following sample codes.

Java - Sample code for disabling SSL checks

```
ns_session.set_certvalidation(false);

ns_session.set_hostnameverification(false);
```

.NET - Sample code for disabling SSL checks

```
ns_session.certvalidation = false;

ns_session.hostnameverification = false;
```

Python - Sample code for disabling SSL checks

```
ns_session.certvalidation = false

ns_session.hostnameverification = false
```

Some points to note with regards to session timeout for NetScaler 10.5 and later versions:

- When restricted timeout param is enabled, NITRO, by default, uses the timeout value that is configured for the logged in user. You can customize this value but it must be limited to the value specified for the user. If no value is specified for the user, the default timeout value of 15 minutes is used.
- When restricted timeout param is not enabled, NITRO uses the default value of 30 minutes as session timeout.

General API Usage

Sep 04, 2015

NetScaler resources are organized into a set of packages or namespaces. Each package or namespace corresponds to a NetScaler feature. For example, all load-balancing related resources, such as load balancing virtual server, load balancing group, and load balancing monitor are available in *com.citrix.netscaler.nitro.resource.config.lb*.

Note: For the python SDK, the package path is of the form *nssrc.com.citrix.netscaler.....*

Similarly, all application firewall related resources, such as application firewall policy and application firewall archive are available in *com.citrix.netscaler.nitro.resource.config.appfw*.

Each NetScaler resource is represented by a class. For example, the class that represents a load balancing virtual server is called **lbvserver** (in *com.citrix.netscaler.nitro.resource.config.lb*). The state of a resource is represented by properties of a class. You can get and set the properties of the class.

Note: The setter and getter properties are always executed locally on the client. They do not involve any network interaction with the NITRO web service. All properties have basic simple types: integer, long, boolean, and string.

Adding a NetScaler Resource

Oct 14, 2015

To create a new resource, instantiate the resource class, configure the resource by setting its properties locally, and then upload the new resource instance to the NetScaler appliance.

The following sample code creates a load balancing virtual server.

Java - Sample code to add a NetScaler resource COPY

```
//Create an instance of the lbvserver class

lbvserver new_lbvserver_obj = new lbvserver();

//Set the properties of the resource locally

new_lbvserver_obj.set_name("MyFirstLbVServer");

new_lbvserver_obj.set_ipv46("10.102.29.88");

new_lbvserver_obj.set_port(88);

new_lbvserver_obj.set_servicetype("HTTP");

new_lbvserver_obj.set_lbmethod("ROUNDROBIN");

//Upload the resource to NetScaler

lbvserver.add(ns_session,new_lbvserver_obj);
```

.NET - Sample code to add a NetScaler resource COPY

```
//Create an instance of the lbvserver class

lbvserver new_lbvserver_obj = new lbvserver();

//Set the properties of the resource locally

new_lbvserver_obj.name = "MyFirstLbVServer";

new_lbvserver_obj.ipv46 = "10.102.29.88";

new_lbvserver_obj.port = 88;

new_lbvserver_obj.servicetype = "HTTP";

new_lbvserver_obj.lbmethod = "ROUNDROBIN";

//Upload the resource to NetScaler

lbvserver.add(ns_session,new_lbvserver_obj);
```

Python - Sample code to add a NetScaler resource COPY

```
#Create an instance of the lbvserver class

new_lbvserver_obj = lbvserver()

#Set the properties of the resource locally

new_lbvserver_obj.name = "MyFirstLbVServer"

new_lbvserver_obj.ipv46 = "10.102.29.88"

new_lbvserver_obj.port = 88

new_lbvserver_obj.servicetype = "HTTP"

new_lbvserver_obj.lbmethod = "ROUNDROBIN"

#Upload the resource to NetScaler

lbvserver.add(ns_session, new_lbvserver_obj)
```

Enabling a NetScaler Resource

Oct 14, 2015

To enable a resource, invoke the **enable()** method and to disable, invoke the **disable()** method.

The following sample code enables a load balancing virtual server named "lb_vip".

Java - Sample code to enable a NetScaler resource COPY

```
lbvserver obj = new lbvserver();

obj.set_name("lb_vip");

lbvserver.enable(ns_session, obj);
```

.NET - Sample code to enable a NetScaler resource COPY

```
lbvserver obj = new lbvserver();

obj.name = "lb_vip";

lbvserver.enable(ns_session, obj);
```

Python - Sample code to enable a NetScaler resource COPY

```
obj = lbvserver()

obj.name = "lb_vip"

lbvserver.enable(ns_session, obj)
```

Retrieving Properties of NetScaler Resources

Oct 16, 2015

To retrieve the properties of a resource, you retrieve the resource object from the NetScaler appliance. Once the object is retrieved, you can extract the required properties of the resource locally, without further network traffic.

The following sample code retrieves the details of a load balancing virtual server.

Java - Sample code to get details of resource COPY

```
//Retrieve the resource object from the NetScaler

new_lbvserver_obj = lbvserver.get(ns_session,"MyFirstLbVServer");

//Extract the properties of the resource from the object locally

System.out.println(new_lbvserver_obj.get_name());

System.out.println(new_lbvserver_obj.get_servicetype());
```

.NET - Sample code to get details of resource COPY

```
//Retrieve the resource object from the NetScaler

new_lbvserver_obj = lbvserver.get(ns_session,"MyFirstLbVServer");

//Extract the properties of the resource from the object locally

Console.WriteLine(new_lbvserver_obj.name);

Console.WriteLine(new_lbvserver_obj.servicetype);
```

Python - Sample code to get details of resource COPY

```
#Retrieve the resource object from the NetScaler

new_lbvserver_obj = lbvserver.get(ns_session,"MyFirstLbVServer")

#Extract the properties of the resource from the object locally

print(new_lbvserver_obj.name)

print(new_lbvserver_obj.servicetype)
```

Filtering Results

You can also retrieve resources by specifying a filter on the value of their properties by using the *com.citrix.netscaler.nitro.util.filtervalue* class.

For example, you can retrieve all the load balancing virtual servers that have their port set to 80 and servicetype to HTTP.

Java - Sample code to get filtered results COPY

```
filtervalue[] filter = new filtervalue[2];

filter[0] = new filtervalue("port","80");

filter[1] = new filtervalue("servicetype","HTTP");

lbvserver[] result = lbvserver.get_filtered(ns_session,filter);
```

.NET - Sample code to get filtered results COPY

```
filtervalue[] filter = new filtervalue[2];

filter[0] = new filtervalue("port","80");

filter[1] = new filtervalue("servicetype","HTTP");

lbvserver[] result = lbvserver.get_filtered(ns_session,filter);
```

Python - Sample code to get filtered results COPY

```
filter_params = []

    filter_params = [ filtervalue() for _ in range(2)]

    filter_params[0] = filtervalue("servicetype","HTTP")

    filter_params[1] = filtervalue("port","80")

    result = lbvserver.get_filtered(ns_session1, filter_params)
```

Retrieving Statistics of NetScaler Resources

Oct 14, 2015

The NetScaler appliance collects statistics about the usage of its features and the corresponding resources. You can retrieve these statistics by using NITRO API. The statistics APIs are available in different packages from the configuration APIs.

For example, the API to retrieve statistics of the load balancing virtual server are available in *com.citrix.netscaler.nitro.resource.stat.lb*.

Note:

- For the python SDK, the package path is of the form *nssrc.com.citrix.netscaler.....*
- Not all NetScaler features and resources have statistic objects associated with them.

The following sample code retrieves the statistics of a load balancing virtual server and displays some of the statistics returned.

Java - Sample code to get feature statistics COPY

```
lbvserver_stats stats = lbvserver_stats.get(ns_session,"MyFirstLbVServer");

System.out.println(stats.get_curclntconnections());

System.out.println(stats.get_deferredreqrate());
```

.NET - Sample code to get feature statistics COPY

```
lbvserver_stats stats = lbvserver_stats.get(ns_session,"MyFirstLbVServer");

Console.WriteLine(stats.curclntconnections);

Console.WriteLine(stats.deferredreqrate);
```

Python - Sample code to get feature statistics COPY

```
stats = lbvserver_stats.get(ns_session,"MyFirstLbVServer")

print(stats.curclntconnections)

print(stats.deferredreqrate)
```

Resetting Properties of a NetScaler Resource

Oct 16, 2015

To unset the value that is set to a parameter, invoke the **unset()** method on the resource class, by passing the name of the resource and the parameters to be unset. If the parameter has a default value, the value is reset to that value.

The following sample code unsets the load balancing method and the comments of a load balancing virtual server named "lb_123".

Java - Sample code to reset properties COPY

```
lbvserver lb1 = new lbvserver();

lb1.set_name("lb_123");

String args[] = {"comment", "lbmethod"};

lbvserver.unset(ns_session, lb1, args);
```

.NET - Sample code to reset properties COPY

```
lbvserver obj = new lbvserver();

obj.name = "lb_123";

String[] args = { "lbmethod","comment" };

lbvserver.unset(ns_session, lb1, args);
```

Python - Sample code to reset properties COPY

```
lb1 = lbvserver()

    lb1.name = "lb_123"

    args = ["comment", "lbmethod"]

    lbvserver.unset(nitroService, lb1, args)
```

Updating a NetScaler Resource

Oct 14, 2015

To update the properties of a resource, instantiate the resource class, specify the name of the resource to be updated, configure the resource by updating its properties locally, and then upload the updated resource instance to the NetScaler appliance.

Note: Some properties in some NetScaler resources are not allowed to be modified after creation. The port number or the service type (protocol) of a load balancing virtual server or a service, are examples of such properties. Even though the update method appears to succeed, these properties retain their original values on the appliance.

The following sample code updates the service type and load balancing method of a load balancing virtual server.

Java - Sample code to update a NetScaler resource COPY

```
//Create an instance of the lbvserver class

lbvserver update_lb = new lbvserver();

//Specify the name of the lbvserver to be updated

update_lb.set_name("MyFirstLbVServer");

//Specify the updated service type and lb method

update_lb.set_servicetype("https");

update_lb.set_lbmethod("LEASTRESPONSETIME");

//Upload the resource to NetScaler

lbvserver.update(ns_session,update_lb);
```

.NET - Sample code to update a NetScaler resource COPY

```
//Create an instance of the lbvserver class

lbvserver update_lb = new lbvserver();

//Specify the name of the lbvserver to be updated

update_lb.name = "MyFirstLbVServer";

//Specify the updated service type and lb method

update_lb.servicetype = "https";

update_lb.lbmethod = "LEASTRESPONSETIME";

//Upload the resource to NetScaler

lbvserver.update(ns_session, update_lb);
```

Python - Sample code to update a NetScaler resource COPY

```
#Create an instance of the lbvserver class

update_lb = lbvserver()

#Specify the name of the lbvserver to be updated

update_lb.name = "MyFirstLbVServer"

#Specify the updated service type and lb method

update_lb.servicetype = "https"

update_lb.lbmethod = "LEASTRESPONSETIME"

#Upload the resource to the NetScaler

lbvserver.update(ns_session, update_lb)
```

Binding NetScaler Resources

Oct 14, 2015

NetScaler resources form relationships with each other through the process of binding. This is how services are associated with a load balancing virtual server (by binding them to it), or how various policies are bound to a load balancing virtual server. Each binding relationship is represented in NITRO by its own class.

To bind one NetScaler resource to another, you must instantiate the appropriate binding class (for example, to bind a service to a load balancing virtual server, you must instantiate the **lbvserver_service_binding** class) and add it to the NetScaler configuration (by using the static **add()** method on this class).

Binding classes have a property representing the name of each resource in the binding relationship. They can also have other properties related to that relationship (for example, the weight of the binding between a load balancing virtual server and a service).

The following sample code binds a service to a load balancing virtual server, by specifying a certain weight for the binding.

```
lbvserver_service_binding bindObj = new lbvserver_service_binding();

bindObj.set_name("MyFirstLbVServer");

bindObj.set_servicename("svc_prod");

bindObj.set_weight(20);

lbvserver_service_binding.add(ns_session,bindObj);
```

```
lbvserver_service_binding bindObj = new lbvserver_service_binding();

bindObj.name = "MyFirstLbVServer";

bindObj.servicename = "svc_prod";

bindObj.weight = 20;

lbvserver_service_binding.add(ns_session,bindObj);
```

```
bindObj = lbvserver_service_binding()

bindObj.name = "MyFirstLbVServer"

bindObj.servicename = "svc_prod"

bindObj.weight = 20

lbvserver_service_binding.add(ns_session, bindObj)
```

Unbinding Resources

To unbind a resource from another, invoke the **delete()** method from the resource binding class, by passing the name of the two resources.

The following code sample unbinds a service from a server.

```
lbvserver_service_binding bindObj = new lbvserver_service_binding();

bindObj.set_name("MyFirstLbVServer");

bindObj.set_servicename("svc_prod");

lbvserver_service_binding.delete(ns_session,bindObj);
```

```
lbvserver_service_binding bindObj = new lbvserver_service_binding();

bindObj.name("MyFirstLbVServer");

bindObj.servicename("svc_prod");

lbvserver_service_binding.delete(ns_session,bindObj);
```

```
bindObj = lbvserver_service_binding()

bindObj.name = "MyFirstLbVServer"

bindObj.servicename = "svc_prod"

lbvserver_service_binding.delete(ns_session, bindObj)
```

Globally Binding NetScaler Resources

Oct 14, 2015

Some NetScaler resources can be bound globally to affect the whole system. For example, a compression policy can be bound to an load balancing virtual server, in which case the policy affects only the traffic on that load balancing virtual server. However, if bound globally, it can affect any traffic on the appliance, regardless of which virtual servers handle the traffic.

Some NITRO classes can be used to bind resources globally. These classes have names that follow the following pattern: **<featurename>global_<resourcetype>_binding**.

For example, the class **aaaglobal_preauthenticationpolicy_binding** is used to bind preauthentication policies globally.

The following sample code creates a preauthentication action and a preauthentication policy that uses that action, and then binds the policy globally at priority 200.

```
aaapreauthenticationaction preauth_act1;

aaapreauthenticationpolicy preauth_pol1;

aaaglobal_aaapreauthenticationpolicy_binding glob_binding;

preauth_act1 = new aaapreauthenticationaction();

preauth_act1.set_name("preauth_act1");

preauth_act1.set_preauthenticationaction("ALLOW");

aaapreauthenticationaction.add(ns_session,preauth_act1);

preauth_pol1 = new aaapreauthenticationpolicy();

preauth_pol1.set_name("preauth_pol1");

preauth_pol1.set_rule("CLIENT.APPLICATION.PROCESS(antivirus.exe) EXISTS");

preauth_pol1.set_reqaction("preauth_act1");

aaapreauthenticationpolicy.add(ns_session,preauth_pol1);

glob_binding = new aaaglobal_aaapreauthenticationpolicy_binding();

glob_binding.set_policy("preauth_pol1");

glob_binding.set_priority(200);

aaaglobal_aaapreauthenticationpolicy_binding.add(ns_session,glob_binding);
```

```
aaapreauthenticationaction preauth_act1;

aaapreauthenticationpolicy preauth_pol1;

aaaglobal_aaapreauthenticationpolicy_binding glob_binding;

preauth_act1 = new aaapreauthenticationaction();

preauth_act1.name = "preauth_act1";

preauth_act1.preauthenticationaction = "ALLOW";

aaapreauthenticationaction.add(ns_session, preauth_act1);

preauth_pol1 = new aaapreauthenticationpolicy();

preauth_pol1.name = "preauth_pol1";

preauth_pol1.rule = "CLIENT.APPLICATION.PROCESS(antivirus.exe) EXISTS";

preauth_pol1.reqaction = "preauth_act1";

aaapreauthenticationpolicy.add(ns_session, preauth_pol1);

glob_binding = new aaaglobal_aaapreauthenticationpolicy_binding();

glob_binding.policy = "preauth_pol1";

glob_binding.priority = 200;

aaaglobal_aaapreauthenticationpolicy_binding.add(ns_session,glob_binding);
```

```
preauth_act1 = aaapreauthenticationaction()

preauth_act1.name = "preauth_act1"

preauth_act1.preauthenticationaction = "ALLOW"

aaapreauthenticationaction.add(ns_session, preauth_act1)

preauth_pol1 = aaapreauthenticationpolicy()

preauth_pol1.name = "preauth_pol1"

preauth_pol1.rule = "CLIENT.APPLICATION.PROCESS(antivirus.exe) EXISTS"

preauth_pol1.reqaction = "preauth_act1"

aaapreauthenticationpolicy.add(ns_session, preauth_pol1)

glob_binding = aaaglobal_aaapreauthenticationpolicy_binding()

glob_binding.policy = "preauth_pol1"

glob_binding.priority = 200

aaaglobal_aaapreauthenticationpolicy_binding.add(ns_session, glob_binding)
```

Deleting a NetScaler Resource

Oct 14, 2015

To delete an existing resource, invoke the static method **delete()** on the resource class, by passing the name of the resource.

The following sample code deletes a load balancing virtual server with name "MyFirstLbVServer".

```
lbvserver remove_lb = new lbvserver();

remove_lb.set_name("MyFirstLbVServer");

lbvserver.delete(ns_session, remove_lb);
```

```
lbvserver remove_lb = new lbvserver();

remove_lb.name("MyFirstLbVServer");

lbvserver.delete(ns_session, remove_lb);
```

```
remove_lb = lbvserver()

remove_lb.name = "MyFirstLbVServer"

lbvserver.delete(ns_session, remove_lb)
```

Performing Bulk Operations

Oct 14, 2015

You can create, retrieve, update, and delete multiple resources simultaneously and thus minimize network traffic. For example, you can add multiple load balancing virtual servers in the same operation. To perform a bulk operation, you instantiate an array of the resource class, configure the properties of all the instances locally, and then upload all the instances to the NetScaler with one command.

Specifying the Bulk Operation Behavior on the NetScaler

To account for the failure of some operations within the bulk operation, NITRO allows you to configure one of the following behaviors while establishing a connection with the appliance.

- **Exit.** When the first error is encountered, the execution stops. The commands that were executed before the error are committed.
- **Rollback.** When the first error is encountered, the execution stops. The commands that were executed before the error are rolled back. Rollback is only supported for add and bind commands.
- **Continue.** All the commands in the list are executed even if some commands fail.

```
nitro_service ns_session = new nitro_service("10.102.29.60","http");

ns_session.set_onerror(OnerrorEnum.CONTINUE);

ns_session.login("admin","verysecret");
```

```
nitro_service ns_session = new nitro_service("10.102.29.60","http");

ns_session.onerror = OnerrorEnum.CONTINUE;

ns_session.login("admin","verysecret");
```

```
ns_session = nitro_service("10.102.29.60","http")

ns_session.onerror = OnerrorEnum.CONTINUE

ns_session.login("admin","verysecret")
```

Bulk Operations

The following sample code creates two load balancing virtual servers.

```
//Create an array of lbvserver instances

lbvserver[] lbs = new lbvserver[2];

//Specify properties of the first lbvserver

lbs[0] = new lbvserver();

lbs[0].set_name("lbvserv1");

lbs[0].set_servicetype("http");

lbs[0].set_ipv46("10.70.136.5");

lbs[0].set_port(80);

//Specify properties of the second lbvserver

lbs[1] = new lbvserver();

lbs[1].set_name("lbvserv2");

lbs[1].set_servicetype("https");

lbs[1].set_ipv46("10.70.136.5");

lbs[1].set_port(443);

//Upload the properties of the two lbvservers to the NetScaler

lbvserver.add(ns_session,lbs);
```

```
//Create an array of lbvserver instances

lbvserver[] lbs = new lbvserver[2];

//Specify details of first lbvserver

lbs[0] = new lbvserver();

lbs[0].name = "lbvserv1";

lbs[0].servicetype = "http";

lbs[0].ipv46 = "10.70.136.5";

lbs[0].port = 80;

//Specify details of second lbvserver

lbs[1] = new lbvserver();

lbs[1].name = "lbvserv2";

lbs[1].servicetype = "https";

lbs[1].ipv46 = "10.70.136.5";

lbs[1].port = 443;

//upload the details of the lbvservers to the NITRO server

lbvserver.add(ns_session,lbs);
```

```
#Create an array of lbvserver instances

lbs = lbvserver[2]

#Specify properties of the first lbvserver

lbs[0] = lbvserver()

lbs[0].name = "lbvserv1"

lbs[0].servicetype = "http"

lbs[0].ipv46 = "10.70.136.5"

lbs[0].port = 80

#Specify properties of the second lbvserver

lbs[1] = lbvserver()

lbs[1].name = "lbvserv2"

lbs[1].servicetype = "https"

lbs[1].ipv46 = "10.70.136.5"

lbs[1].port = 443

#Upload the properties of the two lbvservers to the NetScaler

lbvserver.add(ns_session, lbs)
```

Usage Scenarios

Sep 04, 2015

In this section, we provide NITRO API specific to certain resources and scenarios. We will be adding more scenarios in future updates to this documentation.

Configuring a NetScaler Cluster

Oct 14, 2015

For managing clusters, you can add or remove a cluster instance or an individual node and perform a few other instance or node operations such as viewing instance or node properties. You can also configure the cluster IP address. Other cluster-management tasks include joining a NetScaler appliance to the cluster and configuring a linkset. For detailed information and best practices, see Clustering.

Note: For the python SDK, the package path is of the form *nssrc.com.citrix.netscaler.....*

Cluster Instance Operations

The *com.citrix.netscaler.nitro.resource.config.cluster.clusterinstance* class provides APIs to manage a cluster instance.

The following sample code creates a cluster instance with ID 1.

```
clusterinstance new_cl_inst_obj = new clusterinstance();

//Set the properties of the cluster instance locally

new_cl_inst_obj.set_clid(1);

new_cl_inst_obj.set_preemption("ENABLED");

//Upload the cluster instance

clusterinstance.add(ns_session,new_cl_inst_obj);
```

```
clusterinstance new_cl_inst_obj = new clusterinstance();

//Set the properties of the cluster instance locally

new_cl_inst_obj.clid = 1;

new_cl_inst_obj.preemption = "ENABLED";

//Upload the cluster instance

clusterinstance.add(ns_session,new_cl_inst_obj);
```

```
new_cl_inst_obj = clusterinstance()

#Set the properties of the cluster instance locally

new_cl_inst_obj.clid = 1

#Upload the cluster instance

clusterinstance.add(ns_session, new_cl_inst_obj)
```

Cluster Node Operations

The *com.citrix.netscaler.nitro.resource.config.cluster.clusternode* class provides APIs to manage cluster nodes.

The following sample code adds a cluster node with NSIP address 10.102.29.60.

```
clusternode new_cl_node_obj = new clusternode();

//Set the properties of the cluster node locally

new_cl_node_obj.set_nodeid(0);

new_cl_node_obj.set_ipaddress("10.102.29.60");

new_cl_node_obj.set_state("ACTIVE");

new_cl_node_obj.set_backplane("0/1/1");

//Upload the cluster node

clusternode.add(ns_session,new_cl_node_obj);
```

```
clusternode new_cl_node_obj = new clusternode();

//Set the properties of the cluster node locally

new_cl_node_obj.nodeid = 0;

new_cl_node_obj.ipaddress = "10.102.29.60";

new_cl_node_obj.state = "ACTIVE";

new_cl_node_obj.backplane = "0/1/1";

//Upload the cluster node

clusternode.add(ns_session,new_cl_node_obj);
```

```
new_cl_node_obj = clusternode()

#Set the properties of the cluster node locally

new_cl_node_obj.nodeid = 0

new_cl_node_obj.ipaddress = "10.102.29.60"

new_cl_node_obj.state = "ACTIVE"

new_cl_node_obj.backplane = "0/1/1"

#Upload the cluster node

clusternode.add(ns_session, new_cl_node_obj)
```

Add a Cluster IP Address

The *com.citrix.netscaler.nitro.resource.config.ns.nsip* class provides the **add()** API to configure an IP address. To configure the IP address as a cluster IP address, you must specify the type as CLIP.

The following sample code configures a cluster IP address on NetScaler appliance with IP address 10.102.29.60.

```
nsip new_nsip_obj = new nsip();

//Set the properties locally

new_nsip_obj.set_ipaddress("10.102.29.61");

new_nsip_obj.set_netmask("255.255.255.255");

new_nsip_obj.set_type("CLIP");

//Upload the cluster node

nsip.add(ns_session,new_nsip_obj);
```

```
nsip new_nsip_obj = new nsip();

//Set the properties locally

new_nsip_obj.ipaddress = "10.102.29.61";

new_nsip_obj.netmask = "255.255.255.255";

new_nsip_obj.type = "CLIP";

//Upload the cluster node

nsip.add(ns_session,new_nsip_obj);
```

```
new_nsip_obj = nsip()

#Set the properties locally

new_nsip_obj.ipaddress = "10.102.29.61"

new_nsip_obj.netmask = "255.255.255.255"

new_nsip_obj.type = "CLIP"

#Upload the cluster node

nsip.add(ns_session, new_nsip_obj)
```

Add a Spotted IP Address

The *com.citrix.netscaler.nitro.resource.config.ns.nsip* class provides the **add()** API to configure an IP address. To configure the IP address as spotted, you must specify the ID of the node that must own the IP address. This configuration must be done on the cluster IP address.

The following sample code configures a spotted SNIP address on a node with ID 1.

```
nsip new_nsip_obj = new nsip();

//Set the properties locally

new_nsip_obj.set_ipaddress("10.102.29.77");

new_nsip_obj.set_netmask("255.255.255.0");

new_nsip_obj.set_type("SNIP");

new_nsip_obj.set_ownernode(1);

//Upload the cluster node

nsip.add(ns_session,new_nsip_obj);
```

```
nsip new_nsip_obj = new nsip();

//Set the properties locally

new_nsip_obj.ipaddress = "10.102.29.77";

new_nsip_obj.netmask = "255.255.255.0";

new_nsip_obj.type = "SNIP";

new_nsip_obj.ownernode = 1;

//Upload the cluster node

nsip.add(ns_session,new_nsip_obj);
```

```
#Add a spotted IP address

new_nsip_obj = nsip()

#Set the properties locally

new_nsip_obj.ipaddress = "10.102.29.77"

new_nsip_obj.netmask = "255.255.255.0"

new_nsip_obj.type = "SNIP"

new_nsip_obj.ownernode = 1

#Upload the cluster node

nsip.add(ns_session, new_nsip_obj)
```

Join NetScaler Appliance to Cluster

The *com.citrix.netscaler.nitro.resource.config.cluster.cluster* class provides the **join()** API to join a NetScaler appliance to the cluster. You must specify the cluster IP address and the nsroot password of the configuration coordinator.

The following sample code joins a NetScaler appliance to a cluster.

```
cluster new_cl_obj = new cluster();

//Set the properties of the cluster  locally

new_cl_obj.set_clip("10.102.29.61");

new_cl_obj.set_password("verysecret");

//Upload the cluster

cluster.add(ns_session,new_cl_obj);
```

```
cluster new_cl_obj = new cluster();

//Set the properties of the cluster locally

new_cl_obj.clip = "10.102.29.61";

new_cl_obj.password = "verysecret";

//Upload the cluster node

cluster.add(ns_session,new_cl_node_obj);
```

```
new_cl_obj = cluster()

#Set the properties of the cluster locally

new_cl_obj.clip = "10.102.29.61"

new_cl_obj.password = "verysecret"

#Upload the cluster

cluster.add(ns_session, new_cl_obj)
```

Linkset Operations

The *com.citrix.netscaler.nitro.resource.config.network.linkset* class provides the APIs to manage linksets.

To configure a linkset, do the following:

1. Add a linkset by invoking the **add()** method of the *linkset* class.
2. Bind the interfaces to the linkset using the **add()** method of the *linkset_interface_binding* class.

The following sample code creates a linkset LS/1 and bind interfaces 1/1/2 and 2/1/2 to it.

```
linkset new_linkset_obj = new linkset();

new_linkset_obj.set_id("LS/1");

linkset.add(ns_session,new_linkset_obj);

//Bind the interfaces to the linkset

linkset_interface_binding new_linkif_obj = new linkset_interface_binding();

new_linkif_obj.set_id("LS/1");

new_linkif_obj.set_ifnum("1/1/2 2/1/2");

linkset_interface_binding.add(ns_session,new_linkif_obj);
```

```
linkset new_linkset_obj = new linkset();

new_linkset_obj.id = "LS/1";

linkset.add(ns_session,new_linkset_obj);

//Bind the interfaces to the linkset

linkset_interface_binding new_linkif_obj = new linkset_interface_binding();

new_linkif_obj.id = "LS/1";

new_linkif_obj.ifnum = "1/1/2 2/1/2";

linkset_interface_binding.add(ns_session,new_linkif_obj);
```

```
#Create a new linkset

new_linkset_obj = linkset()

new_linkset_obj.id = "LS/1"

linkset.add(ns_session, new_linkset_obj)

#Bind the interfaces to the linkset

new_linkif_obj = linkset_interface_binding()

new_linkif_obj.id = "LS/1"

new_linkif_obj.ifnum = "1/1/2 2/1/2"

linkset_interface_binding.add(ns_session, new_linkif_obj)
```

Configuring Admin Partitions

Oct 16, 2015

To create an admin partition, you must perform a set of operations on the default partition. To understand this procedure, let us consider a company that has two departments each of which has an application that requires the NetScaler functionality. The NetScaler admin wants to have a different partition for each department so that there is isolation of users and configurations. The NetScaler admin must do the following (the sample shows configurations only for a single admin partition):

Note: For detailed information and best practices, see Admin Partitions.

Creating an Admin Partition

While creating an admin partition, you must also specify the system resources that must be allocated to that partition.

The following sample code creates an admin partition named "partition-dept1".

```
nspartition nspartitionObject = new nspartition();

nspartitionObject.set_partitionname("partition-dept1");

nspartitionObject.set_maxbandwidth(10240);

nspartitionObject.set_maxconn(1024);

nspartitionObject.set_maxmemlimit(10);

nspartitionObject.set_minbandwidth(1240);

base_response result = nspartition.add(nitroService, nspartitionObject);
```

```
nspartition nspartitionObject = new nspartition();

nspartitionObject.partitionname = "partition-dept1";

nspartitionObject.maxbandwidth = 10240;

nspartitionObject.maxconn = 1024;

nspartitionObject.maxmemlimit = 10;

nspartitionObject.minbandwidth = 1240;

base_response result = nspartition.add(nitroService, nspartitionObject);
```

```
nspartitionObject = nspartition()

nspartitionObject.partitionname = "partition-dept1"

nspartitionObject.maxbandwidth = 10240

nspartitionObject.maxconn = 1024

nspartitionObject.maxmemlimit = 10

nspartitionObject.minbandwidth = 1240

result = nspartition.add(nitroService, nspartitionObject)
```

Associating Users with Partitions

Associate the appropriate users with the partition.

The following sample code associates "user1" to a partition named "partition-dept1".

```
systemuser_nspartition_binding systemuser_nspartition_binding_object = new systemuser_nspartition_binding();

systemuser_nspartition_binding_object.set_partitionname("partition-dept1");

systemuser_nspartition_binding_object.set_username("user1");

base_response result = systemuser_nspartition_binding.add(nitroService, systemuser_nspartition_binding_object);
```

```
systemuser_nspartition_binding systemuser_nspartition_binding_object = new systemuser_nspartition_binding();

systemuser_nspartition_binding_object.partitionname = "partition-dept1";

systemuser_nspartition_binding_object.username = "user1";

base_response result = systemuser_nspartition_binding.add(nitroService, systemuser_nspartition_binding_object);
```

```
systemuser_nspartition_binding_object =  systemuser_nspartition_binding()

systemuser_nspartition_binding_object.partitionname = "partition-dept1"

systemuser_nspartition_binding_object.username = "user1"

result = systemuser_nspartition_binding.add(nitroService, systemuser_nspartition_binding_object)
```

Specifying Command Policy for Partition Users

Associate an appropriate command policy to the admin partition user.

The following sample code associates the command policy "partition-admin" to "user1".

```
systemuser_systemcmdpolicy_binding binding_object = new systemuser_systemcmdpolicy_binding();

binding_object.set_username("user1");

binding_object.set_policyname("partition-admin");

binding_object.set_priority(1);

base_response result = systemuser_systemcmdpolicy_binding.add(nitroService,binding_object);
```

```
systemuser_systemcmdpolicy_binding binding_object = new systemuser_systemcmdpolicy_binding();

binding_object.username = "user1";

binding_object.policyname = "partition-admin";

binding_object.priority = 1;

base_response result = systemuser_systemcmdpolicy_binding.add(nitroService,binding_object);
```

```
binding_object = systemuser_systemcmdpolicy_binding()

binding_object.username = "user1"

binding_object.policyname = "partition-admin"

binding_object.priority = 1

result = systemuser_systemcmdpolicy_binding.add(nitroService,binding_object)
```

Specifying the Admin Partition VLAN or Bridgegroup

Specify the VLANs or bridgegroups to be associated with the partition. This step ensures network isolation of the traffic. Traffic received on the interfaces of the VLAN or bridgegroup is isolated from the traffic of other partitions.

The following sample code specifies a VLAN for an admin partition.

```
nspartition_vlan_binding nspartition_vlan_binding_object = new nspartition_vlan_binding();

nspartition_vlan_binding_object.set_vlan(2);

nspartition_vlan_binding_object.set_partitionname("partition-dept1");

base_response result = nspartition_vlan_binding.add(nitroService, nspartition_vlan_binding_object);
```

```
nspartition_vlan_binding nspartition_vlan_binding_object = new nspartition_vlan_binding();

nspartition_vlan_binding_object.vlan = 2;

nspartition_vlan_binding_object.partitionname = "partition-dept1";

base_response result = nspartition_vlan_binding.add(nitroService, nspartition_vlan_binding_object);
```

```
nspartition_vlan_binding_object = nspartition_vlan_binding()

nspartition_vlan_binding_object.vlan = 2

nspartition_vlan_binding_object.partitionname = "partition-dept1"

result = nspartition_vlan_binding.add(nitroService, nspartition_vlan_binding_object)
```

Switching Partitions

If you are associated with multiple admin partitions, you can switch to the required partition.

The following sample code switches from current partition to a partition named "partition-dept2".

```
nspartition nspartitionObject = new nspartition();

vnspartitionObject.set_partitionname("partition-dept2");

base_response result = nspartition.Switch(nitroService, nspartitionObject);
```

```
nspartition nspartitionObject = new nspartition();

nspartitionObject.partitionname = "partition-dept2";

base_response result = nspartition.Switch(nitroService, nspartitionObject);
```

```
nspartitionObject = nspartition()

nspartitionObject.partitionname = "partition-dept2"

result = nspartition.Switch(nitroService, nspartitionObject)
```

Managing AppExpert Applications

Oct 14, 2015

Exporting an AppExpert Application

To export an AppExpert application, you must do the following:

1. Instantiate the *com.citrix.netscaler.nitro.resource.config.app.application* class.

   Note: For the python SDK, the package path is of the form *nssrc.com.citrix.netscaler.....*

2. Configure the properties of the AppExpert locally.
3. Export the AppExpert application.

The following samples export an AppExpert application named "MyApp1".

```
application myapp = new application();

myapp.set_appname("MyApp1");

myapp.set_apptemplatefilename("myapp_template");

application.export(ns_session,myapp);
```

```
application myapp = new application();

myapp.appname = "MyApp1";

myapp.apptemplatefilename = "myapp_template";

application.export(ns_session,myapp);
```

```
myapp = application()

myapp.appname = "MyApp1"

myapp.apptemplatefilename = "myapp_template"

application.export(ns_session, myapp)
```

Importing an AppExpert Application

To import an AppExpert application, you must do the following:

1. Instantiate the *com.citrix.netscaler.nitro.resource.config.app.application* class.

   Note: For the python SDK, the package path is of the form *nssrc.com.citrix.netscaler.....*

2. Configure the properties of the AppExpert locally.
3. Import the AppExpert application.

The following samples import an AppExpert application named "MyApp1".

```
application myapp = new application();

myapp.set_appname("MyApp1");

myapp.set_apptemplatefilename("myapp_template");

application.Import(ns_session,myapp);
```

```
application myapp = new application();

myapp.appname = "MyApp1";

myapp.apptemplatefilename = "myapp_template";

application.Import(ns_session,myapp);
```

```
myapp = application()

myapp.appname = "MyApp1"

myapp.apptemplatefilename = "myapp_template"

application.Import(ns_session, myapp)
```

Exception Handling

Jun 03, 2014

The status of a NITRO request is captured in the com.citrix.netscaler.nitro.exception.nitro_exception class. This class provides the following details of the exception:

- **Session ID.** The session in which the exception occurred.
- **Severity.** The severity of the exception: error or warning. By default, only errors are captured. To capture warnings, you must set the warning flag to true, while connecting to the appliance.
- **Error code.** The status of the NITRO request. An error code of 0 indicates that the NITRO request is successful. A non-zero error code indicates an error in processing the NITRO request.
- **Error message.** Provides a brief description of the exception.

For a list of error codes, see the errorlisting.html file available in the <NITRO_SDK_HOME>/doc/api_reference folder.

NITRO Changes Across Releases

Feb 13, 2017

Some NITRO API have changed across releases. This topic details information which can help you avoid compatibility issues in your application. The changes are categorized as:

- Changes made from 9.3 -> 10.1/10.5
  - Changes across NITRO flavors
  - Changes specific to NITRO SDKs
- Changes made from 10.5 57.x -> 11.0
  - Changes across NITRO flavors
  - Changes specific to NITRO SDKs
- Changes made from 11.0 70.x -> 11.1 53.x
  - Changes across NITRO flavors
  - Changes specific to NITRO SDKs

> **Note**
>
> No changes are introduced from NetScaler 10.1 to NetScaler 10.5. Therefore, you should not face any compatibility issues when migrating from NetScaler 10.1 to 10.5.

The NITRO changes that were made in NetScaler 10.1/10.5 when compared with NetScaler 9.3.

Type of Change	Resource	Method	Attribute
Resource removed	lbmonitor_lbmetrictable_binding ---------- Replaced with the resource 'lbmonitor_metric_binding'.	-	-
	vserver	GET ---------- Perform the GET operation on specific virtual server types such as lb/cr/cs.	-

Method removed	filterpolicy	POST with 'action=unset' ---------- This method is removed as unsetting the attributes('action') of a policy makes it invalid.	-
	auditsyslogpolicy	POST with 'action=unset' ---------- This method is removed as unsetting the attributes('action') of a policy makes it invalid.	-
	auditnslogpolicy	POST with 'action=unset' ---------- This method is removed as unsetting the attributes('action') of a policy makes it invalid.	-
	authorizationpolicy	POST with 'action=unset' ---------- This method is removed as unsetting the attributes('action') of a policy makes it invalid.	-
	snmpengineid	GET ----------	-

Return-type changed		Return type changed to an array.	
	nshostname	GET --- Return type changed to an array.	-
Attribute-type changed	appfwpolicy_lbvserver_binding	-	activepolicy --- Data type changed from Boolean to Integer.
	appfwpolicy_appfwglobal_binding	-	activepolicy --- Data type changed from Boolean to Integer.
	vlan	-	portbitmap --- Data type changed from uint to ulong.
	vlan	-	tagbitmap --- Data type changed from uint to ulong.
	policypatset_pattern_binding	-	indextype --- This attribute is moved to 'policypatset' resource as this attribute is applicable at patset level.
	system_stats	-	powersupply1failure

			---------- Replaced with 'powersupply1status'. Note: Change is applicable from NetScaler 9.3 Build 65.8.
	system_stats	-	powersupply2failure ---------- Replaced with 'powersupply2status'. Note: Change is applicable from NetScaler 9.3 Build 65.8.
	server_servicegroup_binding	-	servicetype ---------- Replaced with 'svctype'.
	server_service_binding	-	servicetype ---------- Replaced with 'svctype'.
	crvserver	-	hits ---------- Hits are calculated per policy binding hence moved this parameter to binding resources.
	crvserver	-	dstvsvr ---------- Replaced with 'destinationvserver'.
Attribute removed	crvserver	-	destvserver ----------

		Replaced with 'domain'.
crvserver	-	dnsvserver --- Replaced with 'dnsvservername'.
appflowpolicylabel	-	type --- Replaced with 'policylabeltype'.
sslcipher	-	ciphgrpals --- Replaced with 'ciphergroupname'.
csvserver_cspolicy_binding	-	targetvserver --- Replaced with 'targetlbvserver'. Note: This change is applicable for the 'sslcipher_*_binding' resources also.
csvserver_cspolicy_binding	-	targetvserver --- Replaced with 'targetlbvserver'.
rewriteaction	-	allow_unsafe_pi1, allow_unsafe_pi --- Replaced with 'bypassSafetyCheck'.
nsconfig	-	nwfwmode ---

			Marked as a hidden attribute.

The SDK-specific changes that were made in NetScaler 10.1/10.5 when compared with NetScaler 9.3.

Type of Change	Class	Method	Replace with...
Class removed	Routerbgp	-	This class is removed as all router configurations are deprecated in 9.2.
Method signature changed	dnsptrrec	get(dnsptrrec obj, nitro_service session)	get(nitro_service session, String reversedomain)
	dnsaddrec	get(dnsaddrec obj, nitro_service session)	get(nitro_service session, String hostname)
	dnsnsrec	get(dnsnsrec obj, nitro_service session)	get(nitro_service session, String domain)
	snmpengineid	unset(nitro_service session, String[] args)	unset(nitro_service session, snmpengineid resource, String[] args)
	arp	arp.get(nitro_service session, String ipaddress)	arp.get(nitro_service session, arp resource)
	nsip	get(nitro_service session, String ipaddress)	get(nitro_service client, nsip resource)
	nsip6	get(nitro_service session, String ipv6address)	get(nitro_service session, nsip6 resource)
	dnsmxrec	dnsmxrec.get(dnsmxrec obj, nitro_service session)	dnsmxrec[] get(nitro_service service, dnsmxrec_args args)
Method	authenticationnegotiatepolicy	(base_response) unset(nitro_service session, String[] args, String name)' is missing in	-

Missing	authenticationnegotiatepolicy	(base_response) unset(authenticationnegotiatepolicy obj, nitro_service session, String[] args)	-
Attribute missing in method	nsconfig	(base_response) update(nsconfig obj, nitro_service session) ---------- 'nwfwmode' attribute is missing in this method.	-

The NITRO changes that were made in NetScaler 11.0 when compared with NetScaler 10.5 Build 57.x.

Type of Change	Resource	Attribute
Attribute removed	nstrace	doruntimemerge
	nstrace	tcpdump
	cacheobject	force

The SDK-specific changes that were made in NetScaler 11.0 when compared with NetScaler 10.5 Build 57.x.

Type of Change	Class	Method	Replace with...
Attribute missing in method	cacheobject	(base_response) flush(cacheobject obj, nitro_service session) ---------- 'force' attribute missing in this method.	-
Method missing	clustersync	(base_response) Force(clustersync obj, nitro_service session)	(base_response) Force(nitro_service session)
	shutdown	(base_response) Shutdown(shutdown obj, nitro_service session)	(base_response) Shutdown(nitro_service session)
	systemfile	(systemfile) get(systemfile obj, nitro_service session)	-

	sslfips	(base_response) reset(sslfips obj, nitro_service session)	(base_response) reset(nitro_service session)

The NITRO changes that were made in NetScaler 11.1 build 53.x when compared with NetScaler 11.0 Build 70.x.

Type of change	Resource	Method	Attribute
Attribute removed	l3param	ALL	overrideIsn **Note**: **overrideIsn** attribute can be set in a net profile.
Attribute removed	sslocspresponder	-	useaia
Attribute removed	sslcertkey_*_binding	-	cerlcheck **Note**: **cerlcheck** attribute is deprecated from release 9.2 and is removed from release 11.1.
Attribute removed	nsconnectiontable	GET	name **Note**: **name** attribute is replaced with **filtername** attribute. **name** in a response carries the name of the TCP profile associated with the connection.
Attribute removed	feoparameter	-	cachemaxage **Note**: Support for setting **cachemaxage** attribute at the global level is removed. This attribute can be set at feo action level.
Attribute removed	iptunnel	-	pbrname Note: **refcnt** attribute returns the number of policy based routes (PBRs) associated with an IP tunnel.
Attribute removed	hanode	-	network
Attribute removed	interface	-	• conndistr • macdistr **Note**: These parameters are deprecated from release 9.2 and is removed from release 11.1.

The SDK-specific changes that were made in NetScaler 11.1 build 53.x when compared with NetScaler 11.0 Build 70.x.

Type of change	Class	Method / Attribute	Notes
Method removed	dnsproxyrecords	flush (nitro_service session)	**flush (nitro_service session)** method is replaced with **flush (nitro_service session, dnsproxyrecords obj)** method.
Attribute type changed	• sslvserver • sslservice • sslservicegroup • sslprofile • sslocspresponder	nonfipsciphers	Access level is changed from read-write to read-only for **nonfipsciphers** attribute. This attribute is removed from add and update methods.
Attribute type changed	nstcpparam	maxpktpermss	The data type is changed from integer to double for **maxpktpermss** attribute.
Attribute type changed	vpnsessionaction	clientoptions	The data type is changed from string-array to string for **clientoptions** attribute. This attribute is deprecated in release 11.1.

Unsupported NetScaler Operations

Sep 29, 2016

The topic lists the NetScaler operations that cannot be performed by using NITRO API.

> **Note**
>
> These operations can be performed on the NetScaler CLI or the GUI.

- install API (supported from NetScaler 11.1 onwards)
- diff API on nsconfig resource (supported from NetScaler 10.5 onwards)
- UI-internal APIs (update, unset, and get)
- show ns info
- shutdown
- Application firewall API
  - importwsdl
  - importcustom
  - importxmlschema
  - importxmlerrorpage
  - importhtmlerrorpage
  - rmcustom
  - rmxmlschema
  - rmxmlerrorpage
  - rmhtmlerrorpage
- CLI-specific API
  - start nstrace/stop nstrace/show nstrace
  - scp
  - configaudit
  - show defaults
  - show permission
  - batch
  - source

Reference Material

Jul 05, 2017

Use this reference information to get an in-depth understanding of the following NetScaler components:

NetScaler SNMP OIDs - Details of the SNMP OIDs that can be used to obtain information from a NetScaler appliance.

NetScaler Syslog Messages - Details of the Syslog messages given by the NetScaler appliance.

NetScaler CLI Commands - Details of the commands that can be used to configure the NetScaler appliance through the CLI. You can also view the details of each command in the NetScaler CLI, by entering the "man <ns-command-name>" command.

API Reference - Details of all operations that can be performed on the NetScaler appliance by using the REST API.

NetScaler Advanced Policy Expressions - Details of the expressions that can be used to define advanced policies.
